Talc (Ger. talk, probably akin to talg, *tallow*). A very widely diffused mineral which enters into the composition of many crystalline rocks, in which it also sometimes forms extensive beds. It is a hydrated silicate of magnesia, rarely met with crystallised, but generally in granular, or foliated, masses of various colours, frequently apple-green or silver-white.

It is met with at Greiner, in the Tyrol; Sahla, Fahlun, and other places in Sweden; the Pyrenees, &c.

Talc forms the basis of the *rouge* used by ladies; it is also employed by tailors for marking lines on cloth, and in a powdered state for making gloves and boots slip on easily, and to diminish the friction of machinery.

Talc Apatite. A variety of Apatite containing magnesia, found in the chlorite-slate of the Schischimskian Mountains, in the Ural.

Talc Spar. [MAGNESITE.]

Talcite. [NACRITE.]

Talent (Gr. τάλαντον). A Grecian weight, which was much used in the computation of money. It contained sixty minæ; but its value varied in different states. The Attic talent was equivalent to about 198*l*. of English money; the Æginetan to 331*l*.

Tales (Lat.). In Law. If by reason of challenges or other causes a sufficient number of jurors do not appear at a trial, either party may pray a tales; i.e. may pray the judge at the trial to allow a sufficient number of qualified men who happen to be present (tales circumstantibus) to be joined with the other jurors to make up the twelve. In practice this seldom arises, except in the case of special jury trials, when the talesmen are taken from the common jury panel in the same court. [JURY.]

Talesfur. An Indian name for the highly fragrant leaves of *Rhododendron Anthopogon*, used as a medicinal snuff in India.

Talionis Lex (Lat.). A punishment in which a person convicted of a crime suffered exactly in the same manner as he had offended: thus an eye was required for an eye, and a tooth for a tooth. This mode of punishment was recognised by the Mosaic law, and was in some cases imitated by the Romans. If, from a more advanced point of view, it appear barbarous, we should not forget that the idea of retaliation is a restriction on the license of unlimited vengeance. The fallacy of the theory is exposed in an apophthegm attributed to Lord Bacon, which states that in Flanders a Flemish tiler fell accidentally on a Spaniard, whom he killed without being hurt himself, and when the next of blood insisted on the lex talionis, the judge remarked that, if he urged that sentence, he should go to the top of the house and then fall down upon the tiler.

Talipat or **Talipot.** The Indian names of certain kinds of Palms, called by botanists *Corypha umbraculifera* and *C. Taliera*.

Talisman (from the Arabic, dual of the noun telesm). Among the Eastern nations, a figure cut in metal, stone, &c., supposed to have been made with particular ceremonies, and under particular astrological circumstances, and to possess various virtues, but chiefly that of averting disease or violent death from the wearer. In a more general sense, any portable object endowed with imaginary influence in controlling evil spirits, &c., has been so designated. The term is frequently used as synonymous with AMULET; but the latter is not believed to possess such extensive powers as the talisman. (See a curious article in the *Encyclopædia Metropolitana*.)

Talkoid. Sparry crystalline Talc from Presnitz.

Tallage (from Fr. taille). In the language of the old English Law, this word is said by Sir E. Coke to be a general name for all taxes. According to the practice of early feudal history in England, the tallage or toll levied by the lord on his dependants, and derivable from the produce of the lands which they held of him, was arbitrary and discretionary in the case of villeins, paid as a rent in that of socagers, and in compensation for military duties in that of tenants by knight service. The power, however, of levying discretionary tallage was checked by the Great Charter; and it appears to have been early held, that the mesne lord could not claim a tallage from his tenants except with the king's consent. By the latter end of the thirteenth century, it is clear that even villeins were exempt from arbitrary tallages. Hence the right of levying a tallage was never so

oppressive as the taille in France. [TAILLE; TOLL.]

Talleh. An Arabic name for the Abyssinian Myrrh, produced by *Acacia Sassa* and *A. gummifera*.

Tallicoonah. A medicinal oil, called also *Kundah oil*, made in Sierra Leone from the seeds of *Carapa guineensis*, sometimes called *C. Touloucouna*.

Tallow (Ger. talg). Animal fat separated from membranous matters by fusion. It consists chiefly of stearin with a small quantity of olein.

Tallow is an article of great importance. It is manufactured into candles and soap, and is extensively used in the dressing of leather, and in various processes of the arts. Besides our extensive supplies of native tallow, we annually import a very large quantity, principally from Russia, whence more than half our imports reach us; the imports of tallow from that country exceeding 30,000 tons a year, while those from Australia and South America may be stated as averaging 4,000 and 2,000 tons respectively: the whole imports into this country from all quarters having been 1,160,219, 1,014,566, and 1,361,248 cwts. in 1863, 1864, and 1865 respectively.

Tallow-tree. *Stillingia sebifera*, the seeds of which are covered with a waxy substance, used in China for making candles.

Tally (Fr. tailler, *to cut*). The practice of keeping a pledge, conveying orders, or guaranteeing accounts by laying two sticks of the same size together, and making similar notches in each, is exceedingly ancient. It was the *symbolum* of the Athenians, probably the SCYTALE of the Spartans, and it was the *tally* of this country; a mode of reckoning only lately antiquated, if indeed it be quite extinct. The same convenience is the basis of the legal *indenture*.

Up to within the last forty years, the public income was checked by tallies made of hazel or ash rods, *indented* and *split into two parts*, one part being retained by the payer, the other by the teller of the exchequer. Daily sales of milk to private families were registered in the same way, as were also the scores kept by brewers against publicans. It is said that the more modern system of account-books is not found to be possessed of checks equal in point of safety to these ancient modes of reckoning.

Talmud. The traditionary or unwritten laws of the Jews. It is called *unwritten*, to distinguish it from the textual or written law; and is, in fact, the interpretation which the rabbins affix to the law of Moses. This interpretation embodies their doctrine, polity, and ceremonies, and to it many of them adhere more than to the law itself. [RABBINISM.]

The word is derived from Heb. lamad, *he taught*. The Talmud, therefore, is a book, or volume, which contains such doctrines and duties as are *taught* to the Jews by their own authorised *teachers*, the ancient rabbins.

There are two Talmuds, that of Jerusalem and that of Babylon: not to mention those of Onkelos and Jonathan, which are rather paraphrases than volumes of traditionary doctrines.

The Talmud of Jerusalem consists of two parts—the *Gemara* and the *Mischna*. The *Mischna* signifies a doubling or reiteration; the *Gemara*, a work brought to perfection or completed—from the Chaldee *gamar*, to finish or complete. The Gemara and the Mischna together, strictly speaking, form the Talmud; but the rabbins sometimes designate the Pentateuch of Moses the *first* part of the Talmud.

The Mischna is the work of Rabbi Judah Hakkadosh, 120 years after the destruction of the temple of Jerusalem. It is written in a tolerably pure style, and its reasonings are much more solid than those of the Gemara, which was written about 100 years afterwards by Rabbi Jochanan, the rector of the school at Tiberias. These two works form the Jerusalem Talmud.

But the Talmud of Jerusalem is less esteemed than the Talmud of Babylon formed by Rabbi Asa or Aser, who had an academy for forty years at a place called Sara, near Babylon, whence it was denominated the Babylonish Talmud. It is this Talmud which the Jews more frequently consult; and it is especially esteemed by those Jews who live beyond the Euphrates from the circumstance that it was compiled at Babylon. Rabbi Asa died before this celebrated commentary on the Mischna was completed; but it was finished by his disciples (some say his children) about 500 years after Christ. With the exception of the sacred authors, these Talmuds, after the Chaldee paraphrases, are the most ancient books of doctrine possessed by the Jews.

A converted Jew in the year 1238 detected several errors in the Talmud, which he laid before Pope Gregory IX., who required the archbishop of France and the kings of Spain and Portugal to seize and burn all such books of the Jews, and twenty cartloads of Hebrew books were accordingly burnt in France alone. Pope Paul IV. and Clement VIII. also signalised themselves in destroying all the Talmudic books that could be found, and many thousand volumes of the Talmud were by their orders juridically condemned to the flames.

The Talmud of Jerusalem was printed in one vol. folio, and that of Babylon in twelve and fourteen vols. folio, which we find in a bookseller's catalogue thus described: 'Talmud Babylonicum Hebraicum integrum ex Sapientum Scriptis et Responsis compositum a Rab. Aser, additis Comment. Rab. Sal. Iarchi et Rab. Mosis Maimonidis, Hebraice, 14 tom. folio, Amstelodami 1644.'

Two curious works on the traditions and doctrines of the Jews, and selections from the Talmud, were written by Peter Stehelin and W. Wotton; the former entitled *Traditions of the Jews with the Expositions and Doctrines of the Rabbins contained in the Talmud and other Rabbinical Writings*, 2 vols. 8vo. 1742; the latter, *Miscellaneous Discourses relating to the Traditions and Usages of the Scribes and Pharisees*

in our Saviour's Time, 2 vols. 8vo. 1718. (*Encyclopædia Metropolitana*; Wolff, *Bibl.* ii. 658; Eisenmenger, *Das entdeckte Judenthum*; Milman's *History of Christianity*; Renan, *Les Apôtres*, Introduction; Remarks on the Study of it in *Quart. Rev.* vol. xliii.) [CABALA.]

Talon (Fr.). In Architecture, the same as OGEE.

Talookdar (Hin.). In India, the holder of a talook, or district, generally smaller than that held by a zemindar, with proprietary rights, concerning the validity and extent of which, in some portions of the old Mogul empire, there has been much dispute: some regarding them as originally mere collectors of revenue, others as possessed of a property in the soil, to whom the actual cultivators are mere subordinate holders. In Oude, in particular, the case of the talookdars, a wealthy and numerous body, has afforded of late much subject of discussion.

Talpa. A genus of burrowing insectivorous mammals called *moles*; of which some species (*T. cæca*, Savi) appear to be blind; others, as our indigenous *Talpa europæa*, have minute eyes and a limited range of vision. The mole is remarkable for the complicated regularity of its subterraneous dwelling and galleries.

TALPA. In Surgery, a tumour under the skin or cuticle, commonly called a *mole*.

Taltalite. A mineral found in large quantities near Taltal, in the desert of Atacama, in Peru, where it forms the bulk of the copper ore derived from the mines. It occurs in masses consisting of an agglomeration of long crystalline fibres of a black or brownish-black colour, and consists chiefly of silicate of copper, together with the silicate of alumina and peroxide of iron.

Talus (Lat. *the ankle*). The sloping heap of fragments accumulated at the foot of a steep rock.

The term *talus* has also been applied to the *astragalus*, one of the bones of the ankle.

Tamanu. A green heavy resin from the Society Islands, obtained from *Calophyllum inophyllum*.

Tamarac. A North American name for the Hackmatack, or American Larch, *Larix americana*.

Tamaricaceæ (Tamarix, one of the genera). An order of hypogynous Exogens, consisting chiefly of shrubs or undershrubs, found growing in maritime sands, or in sandy or gravelly places along torrents in mountain districts. Allied in many respects to *Portulacaceæ*, *Elatinaceæ*, and *Hypericaceæ*, they are at once known by the structure of the ovary, which is not completely divided into cells, but contains three placentas erect from the base of the cavity, these being either quite free, or cohering variously with each other or with the walls of the cavity, so as to form three imperfect cells; and by the erect seeds bearing long hairs.

Tamarindus. This name is supposed to be derived from the Arabic *Tamar*, signifying *dates*, and *Indus*, in allusion to the country whence the tree was originally derived. The Tamarind-tree, *T. indica*, is the only species of the genus, but the East Indian variety has long pods, with six to twelve seeds, whereas the variety cultivated in the West Indies has much shorter pods containing one to four seeds. The

Tamarindus indica (fruit).

tree has an elegant appearance, from its graceful pinnated foliage and its racemes of sweet-smelling flowers. Tamarind-pods, as imported from the East Indies, vary in length from three to six inches, and are slightly curved. They consist of a brittle brown shell, within which is a soft acid brown pulp, traversed by strong woody fibres; the seeds are again immediately invested by a thin membranous covering. West Indian tamarinds are usually imported preserved in syrup, the outer shell having been removed. Tamarinds owe their grateful acidity to the presence of citric, tartaric, and other vegetable acids. In addition to their cooling qualities, they act as gentle laxatives, and are useful in some forms of sore-throat. The pulp mixed with salt is used as a liniment in rheumatism by the Creoles of the Mauritius. The timber is valuable for building purposes, and furnishes excellent charcoal for the manufacture of gunpowder.

Tamarisk. [TAMARIX.]

Tamarite. A Mineralogical synonym for Copper-Mica, from its occurrence at Huel Tamar.

Tamarix (Tamarisia, the people among whom it grows). A name given by botanists to some shrubs of slender growth, known as Tamarisks. They are clothed with very small green leaves and long spikes of pink flowers, the natural country of which seems to extend from Spain to Delhi, occupying a band of ten or twelve degrees of latitude. They represent the order *Tamaricaceæ*.

The Tamarisk will bear exposure to any degree of wind. The stems and leaves abound in sulphate of soda, and a species either closely allied to or identical with the common Tamarisk produces in Arabia a substance considered by the Bedouins a great dainty, and called by them *mann* or MANNA. In the month of June it drops from the branches upon the fallen twigs and leaves, which always cover the ground beneath the tree, and being collected and cleaned is eaten with bread. Some travellers suppose this substance to be not an exudation from the tree, but the produce of an insect which infests the

Tamarisk. It is said to be most abundant in rainy seasons.

Tambac. [TOMBAC.]

Tambookie Wood. A hard handsome wood, which, when powdered, is used by the South African Zulus as an emetic.

Tambourine (Fr. tambourin). A musical instrument of percussion of the drum species, being a cylinder of about six inches long in which bells are suspended. It is covered at one end with parchment, after the fashion of a drum.

Tammela Tantalite. A variety of Tantalite from Tammela, in Finland, containing only a small quantity of tin.

Tamping. A term used by miners to express the filling up of a hole bored in a rock for the purpose of blasting.

TAMPING. In Military Mining, packing with rammed earth, sand-bags, &c. that part of the mine nearest to the charge. This is intended to increase the effect of the charge.

Tamus. Of this, the only European representative of the order *Dioscoreaceæ*, one well-known species, *T. communis*, is the Black Bryony of our hedges. It has thick tuberous roots, sending up annual twining stems, which grow to a great length, and climb over bushes and hedges. The large fleshy roots of the Bryony contain an abundance of acrid clammy juice, and were formerly used in the preparation of stimulating plaisters. Rustic practitioners employ them for removing the discoloration of the skin from bruises. The fruits steeped in gin are a popular remedy for chilblains.

Tang or **Tangle.** The common name of *Laminaria digitata*. The Orkney kelpmen give this name exclusively to the narrow-fronded variety, while the ordinary form is called Cuvy. What is called Black Tangle is *Fucus vesiculosus*.

Tangencies (Lat. tango, *I touch*). In the ancient Geometry, the *problem of tangencies* or *tactions* was one of the six branches of the geometrical analysis created by Apollonius of Perga. Its general object was to describe a circle passing through given points, and touching straight lines or circles given in position, the number of data in each case being, of course, limited to three. Of the treatise of Apollonius some lemmas only were preserved in the mathematical collections of Pappus. From these collections the treatise was restored by Vieta, of whose restoration there is an English translation by Lawson, with the addition of a supplement by Fermat, on Spherical Tangencies. The principal cases of the problem of plane tangencies are given, and neatly demonstrated, in Leslie's *Geometrical Analysis*.

Tangent (Lat. tango, *I touch*). In Geometry, a right line passing through two consecutive points of a curve. If we conceive a right line to rotate around one of its intersection points with the curve until another intersection point comes to coincide with the first, it will in the last position become a tangent. Unless the point on the curve be a MULTIPLE POINT, the tangent at it will be unique; and, unless the curve be of the second order, it will cut the curve again in points which are termed TANGENTIALS. If two of these tangentials coincide with each other, the tangent is termed a DOUBLE TANGENT. A tangent is termed *stationary* when one of the tangentials coincides with the point of contact. [TANGENT, STATIONARY.]

To find the equation to the tangent is a simple problem in the differential calculus which is explained in all text-books. If the equation to the curve, rendered homogeneous by the introduction of a third co-ordinate, z, be $u=0$, the homogeneous equation of the tangent at a point (x_1, y_1, z_1) will be

$$x\frac{du_1}{dx_1} + y\frac{du_1}{dy_1} + z\frac{du_1}{dz_1} = 0,$$

where u_1 denotes what u becomes when x, y, z are replaced by x_1, y_1, z_1. This equation, it will be seen, is that of the *polar line* of x_1, y_1, z_1. [POLES AND POLARS.] Euclid has shown that no straight line can be drawn between a circle and its tangent which does not cut the circle. This property is true of all other curves, and the contact of a curve with its tangent is called a contact of the first order. [CONTACT.]

When rectangular co-ordinates are employed, the term *tangent* is frequently applied to that portion thereof which is intercepted between the point of contact and the abscissa axis. The intercept, on this axis, between the ordinate and the tangent is termed the SUBTANGENT. When polar co-ordinates are used, the portion of the tangent which is intercepted between the radius vector to its point of contact and a perpendicular to this radius vector through the pole, is termed the *polar tangent*; it is expressed by $\frac{r\,ds}{dr}$, where ds denotes the arc-element.

In *Trigonometry*, the ratio of the perpendicular to the base of any right-angled triangle is termed the *tangent of the angle* at the base; and by the *tangent of an arc*, in earlier works on trigonometry, is meant the portion of the tangent at one extremity of the arc intercepted between the radii to the two extremities.

Tangent, Inflectional. [INFLECTIONAL TANGENTS.]

Tangent Plane. In Geometry, it is shown that the tangents at any ordinary point on a surface to the several plane sections through that point all lie in one plane. This is called the *tangent plane* to the surface at the point in question. If the Cartesian equation $U=0$ of the surface be rendered homogeneous by the introduction of a fourth co-ordinate, u, the homogeneous equation of the tangent plane at the point x_1, y_1, z_1, u_1 will be

$$x\frac{dU_1}{dx_1} + y\frac{dU_1}{dy_1} + z\frac{dU_1}{dz_1} + u\frac{dU_1}{du_1} = 0,$$

where $\frac{dU_1}{dx_1}, \frac{dU_1}{dy_1}$ &c. denote what $\frac{dU}{dx}, \frac{dU}{dy}$ &c. become when x, y, z, u are replaced by x_1, y_1, z_1, u_1. In general the tangent plane intersects the surface in a curve which has the point of contact for a double point. [INDICATRIX.] The two tangents to this curve at the double point are termed INFLEXIONAL TANGENTS. Should the latter coincide, the curve will have a cusp, and at an adjacent point thereto will coincide with the original tangent plane, which is then said to be *stationary*.

Tangent Scale. [SIGHTS FOR ORDNANCE.]

Tangent Screw. An endless screw, applied as a tangent at the edge of a toothed wheel, with which the screw gears, and by each revolution of the screw the wheel is turned on its axis the distance of one tooth of the wheel from the next one. Screws of this kind are useful for minute adjustments, as a considerable amount of rotation in the screw gives but a small amount of rotation to the wheel.

Tangent, Stationary. In Geometry, a tangent which meets a curve in *three* consecutive points. The point of contact is called a *point of inflexion*. [INFLEXION, POINT OF.] A curve being regarded as the envelope of a line which turns continually around one of its own *points* (itself in motion), this line becomes a *stationary* tangent when, previous to turning in an opposite direction, its motion is for an instant arrested.

Tangents, Method of. A method, based on kinematical principles, and devised by Roberval in the seventeenth century, for constructing the tangent at any point of a curve. It consists simply in the composition of the several velocities which the generating point is known to possess; for the direction of the resultant velocity will obviously coincide with the required direction of the tangent. Thus the generating point of a parabola may be regarded as having two equal velocities, one along the focal radius vector, and the other parallel to the diameter. Hence we may conclude that the direction of the resultant velocity, in other words, the tangent, will bisect the angle between the radius vector and a parallel to the axis—a well-known theorem. Roberval's method, though still occasionally used, is interesting chiefly as being the forerunner of Newton's more elaborate method of fluxions. An account of it, written by one of Roberval's pupils and containing numerous applications, will be found in the *Mémoires de l'Acad. Roy. des Sciences*, tome vi. Paris 1730.

One of the earliest uses which was made of the differential calculus was to find the positions of tangents to curve lines; and hence the calculus itself, in its early period, was often denominated the *method of tangents*. When the equation of the curve is given, it is easy to find the tangent at any point, as only a simple differentiation is required in addition to the ordinary operations of algebra; but the inverse problem, to determine the equation of the curve when its subtangent at any point is given, requires an integration, and is consequently, in general, attended with much greater difficulty. The first problem was called the *direct*, and the second the *inverse* method of tangents. The terms are synonymous with *differential* and *integral calculus*.

Tangentials. The tangentials of a point on a curve are the intersections with the curve of the tangent at that point. Every point on a curve of the n^{th} order has $n-2$ tangentials. In the case of a cubic, each point has but one tangential, and the tangentials of three points in the same right line are themselves in a right line. [TRANSVERSALS.]

Tanghicin or **Tanguin.** A crystallisable neutral principle said to possess narcotic properties, extracted from the kernel or seed of the *Tanghinia venenifera*, a native of Madagascar. The extract of the seed has been called *Tanginine*.

Tanghinia (Tanghin, its Malagassy name). The Tanghin, or Tanquen, is the only plant belonging to a genus of the *Apocynaceæ*, named *Tanghinia*, confined to Madagascar. *T. venenifera* is a tree with smooth alternate thickish leaves, clustered towards the points of the branches, and bears large terminal cymes of flowers, having a salver-shaped corolla with rose-coloured lobes. The ovary is double, with a long style and thick stigma, but in general only one comes to perfection, forming an ellipsoid fruit, somewhat pointed at the ends, and having a smooth purplish skin tinged with green, containing a hard stone surrounded by a thick fibrous flesh. In Madagascar the natives formerly placed unbounded confidence in the poisonous seed of the Tanghin as an infallible detector of guilt. The portion used as an ordeal is the seed, which is pounded, and a small piece is swallowed by each person to be tried: those in whom it causes vomiting escape, but to those whose stomachs retain it it is quickly fatal, and their guilt is then held to be proven. [ORDEAL BEAN.]

Tanistry (Gael. tanais-teachd). An ancient Irish custom of descent, defined as 'descent from the oldest and worthiest of the blood.' (Sir J. Davies's *Cases before the Irish Judges*, 1762.)

The name, however, is alone local. The custom of tanistry is universal in rude societies, where the security of the administration will not permit a minor or incompetent person to assume the reins of government. The elections of the Merovingian kings in France, of the Gothic kings in Spain, of the Anglo-Saxon kings in England, and, for some time, even of their Norman successors, was determined by the worthiness of any member of the royal house. The principle of an indefeasible hereditary right, resting in one individual, is of later origin. But the worst feature in the Irish custom was its concomitant custom of gavelkind, by which a redistribution of the property possessed by the sept or clan was made on the decease of the

chief; a custom wholly incompatible with the growth of civilisation and wealth.

Tank (Sansc. tanghi, Port. tanque). In Gardening, a cistern, or reservoir, made of stone, slate, timber, or some other material, used in collecting and preserving water during a scarcity or drought. Tanks are sometimes built in the ground, and lined with lead or cement. (Loudon's *Encyc. of Gardening*, p. 603.)

TANK. In the Navy, a case of sheet iron about four feet square, and containing about two tons. Bilge tanks are of various forms, in order to employ the vacant spaces near the sides in small vessels. Wooden casks were formerly employed; but iron tanks have for many years been used in the navy, from their incomparable superiority over casks in keeping the water sweet.

Tannenite. A double sulphide of bismuth and copper found at Tannenbaum in Saxony.

Tanner's Bark. The bark of oak, chestnut, willow, larch, and other trees, which abounds in tannin, and is used by tanners for preparing leather. After being exhausted of the tanning principle by being chopped into small pieces, or bruised, and steeped in water, it is laid up in heaps to dry, and in this state is sold to gardeners for the purpose of producing artificial heat by fermentation in pits or beds, in bark-stoves or pits. [STOVE.]

Tannic Acid. *Tannin.* The pure astringent principle of vegetables, upon which their power of converting skin into leather depends. Its leading character is its property of producing a dense whitish precipitate in a solution of animal jelly, such, for instance, as isinglass. The action of astringents upon persalts of iron has given rise to its distinction into two varieties; the first changing them to deep blue or black, the second to green. The tan of galls, oak-bark, grape-seeds, &c. possesses the former property; that of catechu and tea the latter.

Several varieties of tannic acid are distinguished, as to the sources whence they are obtained, as *gallotannic* acid from gall-nuts, *quercitannic* from oak-bark, *mimotannic* from catechu, &c., each having certain peculiarities, but all agreeing in forming insoluble compounds with gelatine, and producing a black colour with persalts of iron. Tannin occurs in an infinity of plants, and may be detected in their infusions by the tests just mentioned, and by their astringent taste. Gallotannic acid, obtained by the action of washed ether upon powdered galls, may be taken as a specimen of tannin in its purest form; it is yellowish, amorphous, very soluble in water, reddens litmus, and tastes intensely astringent; its aqueous solution absorbs oxygen from the air, and passes into *gallic acid*; when boiled with dilute sulphuric acid, it is resolved into gallic acid and glucose, as shown in the following equation:—

$$\underbrace{C_{54}H_{22}O_{34}}_{\text{Tannic acid.}} + \underbrace{8HO}_{\text{Water.}} = \underbrace{3C_{14}H_6O_{10}}_{\text{Gallic acid.}} + \underbrace{C_{12}H_{12}O_{12}}_{\text{Glucose.}}$$

By digesting powdered charcoal in nitric acid, and carefully evaporating the solution, Mr. Hatchett obtained a brown astringent substance which precipitated gelatine, and which he called *artificial tannin*. (*Phil. Trans.* 1805, 1806.) The uses of tannin are numerous and important: among them may be mentioned especially the manufacture of leather, the formation of black dyes, of writing ink, and its medicinal and dietetic applications.

Tannin. The astringent principle or tannic acid of the bark or galls of the oak and other trees [BARK], of the leaves of sumach [RHUS], and of other vegetable productions, used for tanning leather. The name has reference to its property of combining with the skins of animals, by which they are prevented from becoming putrid, and rendered impervious to water. The process by which this is effected is called *tanning*.

Tansy (Fr. tanaisie). The common name for *Tanacetum vulgare*, a perennial herb of the Composite family. The herb and flower-heads of this plant, used sometimes as a kind of medicinal pot-herb, have a disagreeable though somewhat aromatic odour, and a strong nauseous bitter taste. A small portion is sometimes added to omelets, and Tansy wine enjoys some reputation among rustic practitioners as a stomachic. The curled-leaved variety is a very beautiful plant for garnishing dishes.

Tantalite. Native tantalic acid. It occurs crystallised in iron-black quadrangular prisms, which are mostly incomplete and variously modified. The chief localities where it is found are Finland; Chanteloube, near Limoges, in France; Bodenmais, in Bavaria; and Haddam, in Connecticut. Certain varieties from Finbo, Broddbo, and Kimito, contain a large quantity of oxide of tin. [CASSITEROTANTALITE.]

The metal Tantalum was discovered by Ekeberg in specimens from the last-mentioned locality.

Tantalum. A rare metal, formerly supposed to be identical with columbium. It is found in TANTALITE and YTTRO-TANTALITE.

Tantalus (Gr. Τάνταλος). The myths of Tantalus and Ixion may be considered together, as exhibiting, throughout, the working of the same ideas. These myths exist in many versions, the chief points in each being the following.

Tantalus is represented by some as a son of Zeus, his wife being Euryanassa. His children are Pelops, Broteas, and Niobe, and he is said to have been king of Lydia, of the Phrygian Sipylus, or of Argos. Admitted to the banquet-table of Zeus, he was made acquainted with the secret counsels of the father of gods and men. These, contrary to his promise, he made known, and for this offence he was punished by being placed in the midst of a lake, the waters of which turned to slime when he stooped to drink of them, and under branches laden with fruit, which vanished when he sought to grasp them, while over his head a huge rock suspended in the air threatened constantly to destroy him. Another version relates that, like the sons of

Lycaon, Tantalus served up to Zeus at a banquet the body of his son Pelops, while another says that he stole nectar and ambrosia, and gave them to his people. (Pindar. *Ol.* i. 98.) It is also related that he was intrusted by Pandareos with the care of the dog which had guarded the infant Zeus in Crete, but that when Pandareos demanded back the dog, Tantalus declared that he had never received it.

According to one tradition, Ixion was a son of Phlegyas, and the husband of Dia, the daughter of Hesioneus, to whom he refused to give the rich presents which he had promised for the gift of his child in marriage. When Hesioneus insisted on the performance of the contract, Ixion invited him to a banquet and then let him fall into a pit full of fire. (Diodorus iv. 69.) Zeus alone of all the gods could be induced to purify Ixion from this murder, and Ixion rewarded his kindness by attempting to win the love of HERA. But Zeus placed in his way a phantom resembling Hera, and by this phantom Ixion became the father of the Centaurs. As a punishment for his treachery to Zeus, he was bound on a blazing cross of four limbs, which rolls round in the air for ever and ever. (Pind. *Pyth.* ii. 73.)

Thus these two myths closely resemble each other, while the chief incidents of each recur in other legends, in which the names and details point to mythical phrases indicating the action of the sun. Tantalus lives in a golden palace like that of Helios, from which PHAETHON went forth on his ill-starred journey. His wisdom is the wisdom of Phœbus Apollo (*Hymn to Hermes*, 534), received immediately from Zeus, and which he may not impart even to HERMES. His frequent communings with Zeus are paralleled by the daily visits of Helios to the dizzy heights of heaven. His theft of nectar and ambrosia for the benefit of his friends answers to the stealing of the fire by PROMETHEUS; and in the gifts thus bestowed by Tantalus on his people we see the wealth which the sun brings from the sky and lavishes on the children of men. The hound given to him in pledge by Pandareos is the hound of Artemis, which reappears in the tale of PROCRIS; it is the mighty hound of the gods (the wind), who chases the clouds over seas and mountains, always felt but never seen, and which the sun cannot, therefore, restore. The slaughter of Pelops, although as repulsive as the legend of Erichthonios (Apollodorus iii. 14, 6), may, like that tale, be traced to similar mythical phrases. The warmth of the sun brings to light the fruits of the earth, which is his bride; his raging heat kills his offspring, which is offered up as a scorched and withered victim in the eyes of ZEUS (the sky). His punishment accords not less closely with the meaning of the old mythical expressions. Hermes, who kindles a fire and roasts the sacrifice, cannot appease his hunger, for the wind cannot eat of that which the fire devours. So, like Tantalus, the sun may look on the fruits of the earth or on the clear rivers; but if he stoops to drink and brings his lips near to the laden branches, his breath withers the fruits and dries the streams as in a time of drought, and thus, in the words of the Homeric poet (*Odyss.* xi. 187), only black mud and gaping clay remain in place of flowing water, and the leaves shrivel up beneath the fierce glare of noonday. The rock which hangs over Tantalus and threatens to crush him is the Cyclops Polyphemus [CYCLOPES], and the Theban SPHINX, which broods ominously over the city of ŒDIPUS, both being images of the thunder-cloud, which gathers into the shape of mountains, and remains motionless in the sky until its wrath breaks forth in the storm. [VRITRA.]

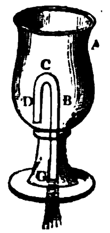
The punishment of Tantalus, which has given rise to the verb *tantalise*, answers to the disappointment of Orpheus when he turns too soon to embrace Eurydikê, who is following him from Hades. In the restoration of Pelops to life we see the operation of that power which is exercised at will by the Colchian MEDEIA. Like that of Eurydikê, the name of Euryanassa, the wife of Tantalus, belongs to that vast class of names which denote the broad flush of light which overspreads the sky at dawn.

Phrases of the same import with those which gave shape to the legend of Tantalus account for the myth of Ixion. Like the name ORPHEUS, the name Ixion is explained by a comparison with the Sanscrit Akshivan, the being who turns on a wheel (Gr. ἄξων, Lat. axis, *axle*). Of this identification, M. Bréal ('Le Mythe d'Œdipe,' *Revue Archéologique* for Sept. 1863) says that no doubt can remain when in Vedic hymns we read of the wheel of the sun, and the battle waged by Dyaus (ZEUS, the heaven) to snatch it from the grasp of night. Thus Ixion loves Hera, the queen of the pure air, as Indra loves the Dawn and Phœbus loves DAPHNE. In his children the Kentaurs [CENTAURS] are seen the Sanscrit Gandharvas, the bright clouds in whose arms the sun reposes as he journeys through the sky. The treasure-house of Ixion answers to the golden palaces of Tantalus and Helios. These are represented as flaming with gold: the treasure-chamber of Ixion is a gulf of fire which scorches the body of Hesioneus, when he insists on the fulfilment of Ixion's promise. The darkness and gloom which follows this deed is a time of plague and drought, answering to that which is brought about by the efforts of Tantalus to appease his thirst. When pardoned for this offence, Ixion incurs deeper guilt, and each day his love for Hera becomes warmer, as the summer sun gains a greater power; but when he seeks to embrace her, she vanishes like Daphne from Phœbus or Eurydikê from Orpheus, and Ixion himself is bound to that four-spoked wheel which figures to the eye the disc of the sun at noontide.

Like Peleus, Ixion has horses which cannot die, and which under the names of Xanthos and Balios are yoked to the chariot of Achilleus. The name of his father Phlegyas (φλέγω) is significant of burning heat, and the withholding of the bridal gifts after the marriage of Dia

corresponds with an incident in the story of Hesionê, where Laomedon, playing the part of Ixion, refuses to give to Heracles the horses which he had promised to him for the rescue of his daughter.

Tantalus's Cup. A philosophical toy which amusingly exhibits the principle of the siphon. Into a hole in the bottom of a cup A the longer leg of a siphon B C D is cemented, so that the end D of the shorter leg nearly touches the bottom of the cup within. When water is poured into the cup, it rises in the shorter leg of the siphon until it reaches the level of the top of the bend at C, when it flows over into the larger leg, and is carried off at G; so that if water is not supplied to the cup faster than it is drawn off by the siphon, the cup will be emptied.



To form the toy, the legs of the siphon are concealed by the hollow figure of a man whose chin is on a level with the bend of the siphon; so that the figure stands like Tantalus in the fable—up to the chin in water, but unable to quench his thirst.

Tantipartite Function. This term denotes a function which is linear with respect to several distinct sets of quantities. Thus, a determinant is a tantipartite function, the elements in each line or column constituting a set. When there are only two sets of facients, the function is said to be *lineo-linear*; an example of such a function, x, y, and x', y' being the two sets of facients, is

$$axx' + bxy' + cx'y + dyy'.$$

Tanystomes (Gr. τανύω, *I stretch*, and στόμα, *a mouth*). The name of a family of Dipterous insects, comprehending those which have a projecting proboscis, with the last joint of the antennæ undivided.

Tanystropheus (Gr. τανύω, and στρέφω, *to twist*). A genus of Sauropterygian Reptilia, in which the longitudinal diameter of the vertebræ was greater than in any other vertebrate animal, recent or fossil.

Tap Root. The main root of a plant, which strikes perpendicularly into the soil. It is sometimes succulent with few fibres, as in the carrot and radish; sometimes woody with many horizontal ramifications, as in the oak-tree. This tap root grows in advance of the other roots, and acts as a sort of anchor to keep the tree firm in the ground; hence, in transplanting trees or shrubs, it should never be divided.

Tap-rooted. Having a large simple conical root, which forms a centre round which the divisions are arranged.

Tape-worm. [Tænia.]

Taper (A.-Sax.). In Botany, this term is applied to parts the opposite of angular; usually employed in contradistinction to that term, when speaking of long bodies. [Terete.]

Tapestry (Fr. tapisserie, from tapis, Lat. tapete). An ornamental figured textile fabric of worsted or silk for lining the walls of apartments. Of the earlier manufactories of this kind were those of Arras, Brussels, Antwerp, and Valenciennes. Those of Arras were executed chiefly in wool with a little hemp and cotton, but without silk or gold or silver thread. The best known tapestry is now produced at the Gobelins royal manufactory near Paris.

In Painting, the word *tapestry* is applied to a representation of a subject in wool or silk, or both, worked on a woven ground of hemp or flax.

Tapioca. The prepared starch of the root of the *Manihot utilissima*, employed as a diet for invalids. The root abounds with a milky juice, which is poisonous, but which deposits an inert starch when diffused through water. It is called *Cassava*, and is rendered harmless by boiling.

Tapir. The name of a genus of Perissodactyle Mammals, of which three existing and several extinct species have been determined. Of the existing species one is a native of Sumatra, the other two of South America. They have a short proboscis; four toes on the fore foot, and three toes on the hind foot.

Tar (A.-Sax. tare, Ger. theer). A dark brown or black viscid liquid obtained in the destructive distillation of organic matters. There are three principal kinds of tar: *wood tar*, obtained in the manufacture of wood vinegar and wood spirit by the destructive distillation of wood; *Stockholm tar*, largely used in the arts, as in shipbuilding, &c., which is obtained by a rude distillatio per descensum of the roots and other useless parts of the resinous pine; and *coal tar*, obtained during the destructive distillation of coal in the manufacture of coal gas. The tars are extremely complex mixtures. Wood tar yields on repeated fractional distillations paraffin, eupion, picamar, kapnomor, cedriret, and creosote. The residue left in the retort constitutes pitch, and from it the two hydrocarbons chrysen and pyren have been obtained. Coal tar by distillation furnishes carbolic acid or phenol; cresylic alcohol; xylylic alcohol; the liquid hydrocarbons benzol, toluol, xylol, cumol, and cymol; the solid hydrocarbons naphthalin, paranaphthalin, and paraffin; rosolic and brunolic acids; and the basic compounds aniline, cespitine, pyridine, picoline, lutidine, collidine, parvoline, coridine, rubidine, viridine, leucoline, cryptidine and pyrrol.

In former days, *tar water*, under the authority of Bishop Berkeley, was considered as a universal remedy, more especially in rheumatic, syphilitic, and cutaneous affections. The bishop's practice was ridiculed with much point and effect in a pamphlet by Mr. Reeve, entitled *A Cure for the Epidemic Madness of Drinking Tar Water*, in which he says: 'In your younger days, my lord, you made the surprising discovery of the unreality of matter, and

now in your riper age you have undertaken to prove the reality of an universal remedy; an attempt to talk men out of their reason did of right belong to that philosopher who at first tried to reason them out of their senses.'

Tar, Mineral. A viscid variety of Bitumen, much resembling Petroleum.

Tara. An Indian name for *Corypha Taliera*, the Talipat Palm.

Taranis. In Mythology, a Celtic divinity, confounded by Latin writers with their Jupiter. (Lucan, *Phars.* i. 446.)

Tarantella. [Tarantula.]

Tarantula (so called from Taranto in Sicily). The name of a Fabrician genus of pedipalpous pulmonary Arachnidans, infesting the torrid regions of Asia and America. The group is now divided into the genera *Phrynus* and *Thelyphonus*. The term is also applied to a genus of spiders found in some parts of Sicily, whose bite produces a train of symptoms long believed to be curable only by music. From this word is derived the term *tarantella*, the national dance of the Sicilians.

Taraxacin. A crystallisable bitter principle contained in the juice of the root of dandelion (*Taraxacum dens leonis*).

Taraxacum. The Dandelion, one of our most familiar weeds, is the type of this genus of Composites. This plant, the *T. dens leonis*, is universally found in Europe, Central Asia, North America, and the Arctic regions, and varies much in stature and appearance, according to the locality in which it grows. The rootstock is extensively used in medicine as an aperient and tonic, especially in liver-complaints. It has also diuretic properties, and may be used in the same manner as chicory. The leaves are eaten by cattle with advantage, and are greedily devoured by rabbits.

The bright yellow flowers of this plant open in the morning between five and six o'clock, and close in the evening between eight and nine—hence this was one of the plants selected by Linnæus to form his floral clock.

Tardigrades (Lat. tardus, *slow*; gradior, *I march*). A family of edentate Mammals, comprising those which are remarkable for the slowness of their motions when upon the ground, as the sloths.

Tardo (Ital. *slow*). In Music, a term denoting that the movement to which it is affixed is to be performed slowly. It is nearly the same in signification as *largo*.

Tare. In Agriculture, the name of the common Vetch (*Vicia sativa*).

Tare. In Commerce, tare is a deduction made from the weight of goods by taking into account the weight of the packing. It is said to be *real*, when the true weight of such a packing is estimated; *average*, when a few similar cases are taken, and the average estimated as equal on all the cases; *customary*, when a uniform weight is taken as the rule of the place. Some of the weights found in England, as the hundred of 112 lbs. and probably the pound of 16 ounces, were originally inclusive of the tare. The hundred passed through another stage when it was reckoned at 108 lbs.

Targum. A Chaldee word, denoting, generally, the Chaldee, or more properly Aramaic, versions of the Old Testament; the two best known being those of Jonathan Ben Uzziel (or rather the Pseudo-Jonathan), an author who wrote a paraphrase or commentary upon the Greater and Lesser Prophets, about B.C. 30; and of Onkelos, upon the Pentateuch, which is considered the most valuable of all, and is referred to the first century of our era. (*Ency. Met.*; see also the treatise on this subject, under the head 'Versions,' by Mr. Emanuel Deutz, in Smith's *Dictionary of the Bible*.)

Tari. The sap of *Phœnix sylvestris*, which is drunk in India either fresh or fermented.

Tariff. A table arranged alphabetically, and containing a schedule of all duties, &c. levied upon imports and exports. This name is taken from the Spanish town Tarifa, at the entrance of the straits of Gibraltar, where duties were formerly collected. The English tariff, till the reforms of Sir Robert Peel, was exceedingly lengthy, but it is now confined to very few articles. Changes in tariffs have been the prominent purposes of those acts of commercial diplomacy which have been entered upon between this and other countries of late years.

Tarnowitzite. A variety of carbonate of lime, or species of Aragonite, containing a small proportion of lead; found at Tarnowitz in Upper Silesia.

Taro. The tuberous roots of *Caladium esculentum*, *Colocasia macrorhiza*, &c.

Tarpawling or **Tarpauline.** A painted or tarred canvas cover.

Tarpeia. In Roman Mythology, the maiden who gave her name to the Tarpeian rock. According to one story, she agreed to open the gates of the city to the followers of Titus Tatius, bargaining with them that they should give her what they wore on their left arms; but they threw upon her their shields instead of the bracelets which she had desired. In another version, she wishes to deceive the Sabines, and not to favour them; while in a third legend she is described as betraying the Capitol to a king of the Gauls of whom she was enamoured, and not to a king of the Sabines. (Sir G. C. Lewis, *Credibility of Early Roman History*, ch. xi. sect. 4.)

Tarras, Terras, or **Trass.** A volcanic product of the nature of pozzuolano. Mixed with ordinary mortar, it gives the resulting material the property of setting or hardening under water. Several argillo-ferruginous minerals possess the same property, and are indiscriminately used under this term. [Pozzuolano.]

Tarse or **Tarsus** (Gr. ταρσός, *sole of foot*). In Mammalia, this word signifies the collection of small bones between the tibia and metatarsus, or those which constitute the first part of the foot. In birds, it is sometimes applied

to the third segment of the leg, which is rarely fleshy or feathered, and corresponds with the tarsus and metatarsus conjoined. In insects, it signifies the aggregate of minute joints which constitute the fifth principal segment of the leg or the foot.

Tartar (Gr. τάρταρος, *the nether world*, because it is the sediment or dregs of wine). The substance which concretes upon the inside of wine casks. It is called *red* and *white argol*, according to the wine from which it is obtained. When purified, it is often called *cream of tartar*: it is a bitartrate of potash. [TARTARIC ACID.]

Tartar Emetic. [EMETIC TARTAR.]

Tartar of the Teeth. This substance, which occasionally concretes upon the teeth, consists, according to Berzelius, of—

Salivary mucus	13·5
Animal matter soluble in muriatic acid	7·5
Phosphate of lime (earthy phosphates)	79·0
	100·0

Tartaric Acid. The acid of tartar. This acid, which in its ordinary state may be represented as = (2HO, $C_8H_4O_{10}$), is found free, and in combination, in many vegetables; its principal source is in the juice of the grape, in which it exists in the form of *tartar*, or bitartrate of potash. The acid is obtained from this salt as follows: 4 parts of it, in fine powder, are well mixed with 1 part of powdered chalk, and the mixture thrown, by small portions at a time, into 10 parts of boiling water. When the effervescence is over, the whole is stirred and left to subside. The liquid, which is a solution of neutral tartrate of potash, is then poured off the sediment, which is tartrate of lime, and a solution of chloride of calcium is added to it. This throws down an additional portion of tartrate of lime, which is mixed with the first, and having been well washed, is decomposed by dilute sulphuric acid. This forms sulphate of lime, while the tartaric acid remains in solution, and is obtained by slow evaporation. The first crystals require to be redissolved, and digested with a little purified animal charcoal until the liquid is colourless; it is then again evaporated and crystallised.

Tartaric acid is very sour; its crystals exhibit complicated forms, derived from an oblique rhombic prism. Water dissolves about 1·5 its weight at 60°, and more than twice its weight at 212°. It is also soluble in alcohol.

Tartaric acid is distinguished by the white crystalline precipitate which it produces when added in excess to solutions containing potash. If these solutions are very dilute, the precipitation is accelerated by the addition of alcohol. It is used in calico printing, and is much employed as a cheap substitute for citric acid in lemonade and in effervescent solutions.

Pasteur has shown that there are two modifications of tartaric acid. The crystals of one variety, when dissolved in water, turn the plane of polarisation to the right—*dextro-tartaric*, or the common tartaric acid. The crystals of the other variety, when dissolved in water, turn the plane to the left—*lævo-tartaric acid*. It is remarkable that when equal parts of the two acids are mixed, crystals are deposited from the mixture, which appear to be identical in properties with racemic or paratartaric acid; they have no action on a ray of polarised light.

The *Tartrates* are mostly crystallisable, and are either neutral or acid. In the neutral tartrates 2 atoms of base are combined with 1 atom of acid, as in neutral tartrate of potash, which is 2(KO), $C_8H_4O_{10}$, or in tartrate of potash and soda, = KO,NaO,$C_8H_4O_{10}$. In the acid tartrates (or bitartrates) 1 atom of water replaces 1 of the bases, as in bitartrate of potash, which is KO,HO,$C_8H_4O_{10}$. There is also an important class of tartrates in which one of the bases is a protoxide and the other sesquioxide, the salt being neutral, as in the tartrate of potash and antimony (emetic tartar), which is KO,SbO_3,$C_8H_4O_{10}$. *Tartrate of potash*, used as an aperient under the name of *soluble tartar*, forms prismatic crystals of a saline and bitter taste, soluble in 2 parts of water. *Bitartrate of potash* or *Tartar* exists in the juice of the grape, and is deposited in wine casks in the form of a white or red crystalline incrustation, called *argol* or *crude tartar*. It is purified by dissolving it in boiling water, with one-twentieth of its weight of pipeclay, which absorbs the colouring-matter, and falls as a sediment, the crystals of tartar separating afterwards upon the surface of the liquor, and upon the sides and bottom of the boiler; the term *cream of tartar* was originally applied to the superficial crust.

The acid tartrate of potash is also formed by adding excess of tartaric acid to a solution of potash: the mixture presently deposits crystalline grains, and furnishes an example of diminution of solubility by increase of acid in the salt. Upon this the use of tartaric acid as a *test* for potash depends; for soda forms an easily soluble supertartrate, and affords no precipitate.

The crystals of this salt, which are rhombic prisms, are soluble in 184 parts of water at 68°; and in 18 parts at 212°.

Tartrate of Potash and Soda is prepared by saturating the excess of acid in tartar, with carbonate of soda. It is the *Soda tartarizata* of pharmacy, and forms fine transparent prismatic crystals. This salt has long been used as a mild aperient, under the name of *Rochelle Salt* and *Sel de Seignette*, having been first prepared at Rochelle by an apothecary of the name of Seignette.

Tartrate of Lime is often found as a crystalline deposit in light white wines. It falls on dropping tartaric acid into lime-water, and is soluble in excess of the acid.

Tartrate of Potash and Antimony. [EMETIC TARTAR.]

When common tartaric acid is heated to

about 350°, it fuses and congeals on cooling into a vitreous mass, which has the same saturating power as the original acid, but which produces salts differing in crystalline form. If the heat exceed 360°, the acid becomes monobasic, but still without loss of weight, and is represented by $HO,C_8H_5O_{11}$. These isomeric modifications have been designated *metatartaric* and *isotartaric* acids: when solutions of their salts are boiled, they gradually revert to common tartrates. When the common acid is kept in fusion at about 372°, it loses half an equivalent of water, and is changed into *tartralic acid*. When the temperature of the fused acid is raised to 392°, it loses an equivalent of water, and becomes *tartrelic acid*. The tartralates and tartrelates are converted into tartrates, when boiled with water. By carefully continuing the action of heat on tartaric acid, it may be obtained *anhydrous*; it is then white, amorphous, and insoluble in cold water; but by the protracted action of water, or by boiling, it reverts to its ordinary condition, by the resumption of two atoms of water.

The relations of the anhydrous tartaric acid to its several hydrated modifications, are as follow:—

Anhydrous tartaric acid . .	$C_8H_4O_{10}$	
Crystallised tartaric acid . .	$C_8H_4O_{10}$	2HO
Metatartaric acid	$C_8H_4O_{10}$	2HO
Isotartaric acid	$C_8H_8O_{11}$	HO
Tartralic acid	$2(C_8H_4O_{10})$	3HO
Tartrelic acid	$C_8H_4O_{10}$	HO
Racemic acid	$C_8H_4O_{10}$	2HO

Tartarus (Gr. *τάρταρος*). In Greek Mythology, a son of Æther (air) and Gê (earth), and the father of Typhoeus and ECHIDNA. In the *Iliad* the name Tartarus denotes a place, closed in by iron gates, as far below HADES as heaven is above the earth. In the Platonic dialogue entitled *Gorgias*, Tartarus is the place where the souls of men pay the penalty for the evil deeds done during their lifetime on earth. [SOUL.]

Tartrates. Salts in which the tartaric acid is combined with bases. [TARTARIC ACID.]

Tartrovinic Acid. An acid composed of tartaric acid, in which an atom of water has been replaced by oxide of ethyl (C_4H_5O).

Tartuffe. A common French nickname for hypocritical pretenders to devotion. It is derived from the celebrated comedy of Molière, of which the hero is so called. Whether Molière invented it, or took it from the popular language of the time, does not appear: some say that he intended to attack the confessor of Louis XIV., Père la Chaise, whom he had once seen eating truffles with peculiar goût; and thence the name. The play was written in 1664, but not acted till 1669; great difficulties being thrown in the way of the author by the clergy and the papal legate. On one occasion it was prohibited when the curtain was on the point of rising, and Molière announced to the public its disappointment in the well-known equivocal words, 'Monsieur le président ne veut pas qu'on le joue.' When at last licensed (through the influence, it is said, of the king himself), it had a run of three months with unparalleled success. In England, this play has been made more than once to serve the popular passions of the day. Cibber translated it, and made the hero a nonjuring churchman; and the play is still acted under the name of *The Hypocrite*, in which the Tartuffe is a methodistical divine.

Tasmanite. A mineral of organic origin. It is a hydrocarbon containing a little more than five per cent. of sulphur, and occurs in the form of minute discs, which constitute from 30 to 40 per cent. of the resiniferous shale from the river Mersey on the north side of Tasmania.

Tasmannia (after Tasmann, the Dutch navigator, the discoverer of the island now called Tasmania). A genus of *Magnoliaceæ*, consisting of one Tasmanian and two Australian species, closely allied to *Drimys*. *T. aromatica*, the Tasmanian species, possesses, as its specific name implies, aromatic qualities, particularly in its bark, which so closely resembles the Winter's Bark of Magalhaen's Straits (*Drimys Winteri*), that it is substituted for it by colonial doctors. The colonists call it the Pepper-plant, and use its little black pungent fruits as a substitute for pepper. Under the microscope the wood exhibits a structure resembling that of many coniferous plants, the fibres being marked with similar circular discs.

Taste (Fr. tâter; Ger. tasten; akin to Lat. tango, tactum, *to touch*). That power of the mind which is concerned with the beautiful, both in nature and of art. In the Latin language, the same metaphor obtained a very wide application, and the term *sapientia* was employed to signify quickness and correctness of judgment generally. Shaftesbury's use of the term is nearly as extensive, being applied by him to manners, morals, and government, and to wit, ingenuity, and beauty. In its modern use it is restricted to those objects which fall within the province of imagination. As applied to the Fine Arts, taste must be supposed to mean an intellectual perception of any object, blended with a distinct reference to our sensibility of enjoyment or dislike.

Coleridge defines the term *taste* as a metaphor taken from one of the mixed senses, and applied to objects when we would imply the coexistence of an immediate personal dislike or complacency. Now, by the constitution of man's nature, every exertion of human activity in the pursuit of the good, the beautiful, and the true, combines a sense of pleasure or the contrary with the perception of their respective objects; and this fact would justify the widest application of the metaphor. While, however, in the case of the true, this coexistent pleasure has not received any distinctive appellation, and while conscience, as comprehending the sense of approbation and disapprobation, is characteristically applied to the moral energy, taste has been confined to the perception of beauty and the accompanying gratification.

But by directing attention exclusively to this element of pleasure, the term has led to a very inadequate conception of the true nature of the faculty which it designates. Thus Hutcheson (*Inquiry into the Idea of Beauty and Virtue*) maintains that the faculty is peculiar, that beauty strikes at first sight, and that knowledge the most perfect will not increase the pleasure to which it gives rise; and, lastly, that all the diversity of sentiments excited in different minds by the beautiful arises solely from the modifications of the sense by association, custom, example, and education. Among the advocates of the theory of a moral taste we may reckon Hume, Akenside, Blair, Lord Kames, and Beattie.

Blair defines taste to be the power of receiving pleasure from the beauties of nature and art; while Akenside describes it as 'certain internal powers feelingly alive to each finer impulse.' Beattie (*Essay on Poetry and Music*) supposes taste to have its origin in a mutual harmony and sympathy between the soul in its first formation and the rest of nature. In the *Essay on the Delicacy of Taste*, Hume talks of it as a natural sensibility; while in the *Essay on the Standard of Taste*, he seems to admit of no other criterion than the decisions of a due and sufficiently extensive experience. Lastly, Lord Kames declares a taste in the fine arts to be nearly allied to the moral sense; but yet, like morals, capable of being raised to a rational science by an examination of the sensitive branch of the human constitution, and an enumeration of the objects which are either agreeable or disagreeable by nature.

But taste is not only a sensitive, it is also a cognitive faculty. When a beautiful object is presented to the mind, not only does it make on it an impression of pleasure, but the mind in the first place passes judgment upon it, and declares it to be beautiful, i.e. conformable to a standard called the beautiful. In this complex operation of taste, the judgment is the antecedent, and the pleasure the consequent. When the impassible judgment has passed sentence upon the object, then the sensibility is awakened to certain sentiments, which are, as it were, the echo of the reason. (Cousin, *Sur le Vrai, le Bien, et le Beau.*)

The same conclusion will follow from an examination of some of the principal definitions of beauty. According to St. Augustine (*Ep.* 18), 'unity is the universal form of beauty;' and to Malespina (*Delle Leggi del Bello*), 'beauty consists in unity, multiplicity, and propriety.' De Crousaz (*Traité du Beau*) makes beauty to consist in variety, unity, regularity, order, and proportion. Winckelmann and Sulzer agree also in making unity and multiplicity to be essential constituents of the beautiful. And, lastly, the definition of beauty in the Italian schools of painting, was, 'il più nell' uno'—variety in unity; which is nearly identical with Hutcheson's explanation of it—uniformity in variety.

A few definitions of beauty remain to be noticed, which apparently favour the theory of Hutcheson. According to Burke (*On the Sublime and Beautiful*) and Price (*Essay on Beauty*), beauty consists in such qualities as induce in us a sense of tenderness and affection. Alison declares that the qualities of matter are neither beautiful nor sublime in themselves, but only such so far as they are signs or expressions of qualities capable of producing emotion. Wieland makes beauty to consist in the unity of an *agreeable* variety; and Kant teaches that the beautiful pleases irrespectively of any idea of utility, or of any conception of design, simply by the correspondence of the object and the sensitive organ.

The emotions of taste are usually distinguished into those of the sublime and beautiful; but Dugald Stewart seems with justice to have denied the existence of any intrinsic difference between them. According to Burke, indeed, the terrible is a fruitful source of the sublime; and this idea does not seem capable of being made an ingredient of the beautiful. In the same way, on the other hand, there are ideas eminently beautiful which can never give rise to an emotion of sublimity. Nevertheless this does not constitute an essential difference between the two. It is with reference to their several effects upon the imagination that they may perhaps be most correctly distinguished. Considered in itself, a beautiful object ought to present the greatest possible unity combined with the greatest possible variety; and considered in its effect upon the mind, its beauty consists in the free, facile, and harmonious play of the imagination. On the other hand, the imagination is lost and overpowered in the contemplation of the sublime, which in its infinity presents at once unity and variety.

Tasto. In Music, a term used in conjunction with *solo*, to signify that the instruments which can accompany by chords are to play only single sounds till the direction is contradicted by the word *accordo* or *accompanimento*.

Tatta (Indian). A bamboo frame or trellis, over which water is suffered to trickle with a view of cooling the air as it enters the windows or doors.

Tattie. An Indian name for window or door screens made from split bamboo.

Tattooing. The art of puncturing the skin and inserting in the slight wounds thus made a coloured fluid or powder so as to produce a permanent stain. It is an ancient custom adopted by savage and by civilised nations. The device to be imprinted is first drawn or stamped upon the part; the lines are then pricked out by a pointed wire, and gunpowder, Indian ink, or some other colouring matter, immediately rubbed over the punctures so as to insinuate itself into the cutis, where it becomes indelible. (*United Service Mag.* 1844, p. 495.)

Taurin. A crystalline substance obtained by the transformation, under the influence of

acids or alkalies, of Taurocholalic acid, one of the constituents of bile. It may also be prepared by the action of heat upon isethionate of ammonia. Its composition is $C_4H_7NO_6S_2$.

Tauriscite. A mineral isomorphous with Epsomite, from Windgalle in the Canton of Uri (the *pagus Tauriscorum*, whence the name).

Taurocholalic Acid (formerly called *choleic acid* and *bilin*). A constituent of bile. It has not been obtained in the pure state, but from its decompositions the formula has been inferred to be $C_{52}H_{44}NS_2O_{13}HO$.

Taurus (Lat. *the Bull*). In Astronomy, the second in order of the twelve zodiacal constellations. There are several remarkable stars in this constellation: Aldebaran, of the first magnitude, in the eye; the well-known cluster called Pleiades in the neck; and the Hyades in the face. [CONSTELLATION; ZODIAC.]

Taut. In Sea language, tight, neat, properly ordered, prepared against emergency.

Tautochrone (Gr. ταὐτό, *the same*, and χρόνος, *time*). In Mechanics, a curve line, having this property that a heavy body descending along it by the action of gravity will always arrive at the lowest point in the same time, wherever the point from which the body begins to fall be taken in the curve. Huygens first showed that this property of *tautochronism* belonged to the common cycloid when the motion takes place in a vacuum, and gravity is supposed to act in parallel straight lines. [CYCLOID.] Newton and Hermann also determined the tautochrone in a vacuum, when gravity is supposed to be directed towards a given centre. Newton likewise showed that the cycloid is also the tautochrone in a resisting medium, when the resistance is proportional to the velocity (*Principia*, b. ii. prop. 26); and Euler first determined the nature of the tautochronous curve when the resistance is proportional to the square of the velocity. (*Mechanica*, vol. ii.; Joh. Bernoulli, *Opera*, vol. iii.)

Tautolite. A mineral resembling Hyalosiderite, found in volcanic rocks, near Lake Laach. The name is an abbreviation of Tautometrolite (Gr. ταὐτό, *the same*; μέτρον, *a measure*, and λίθος, *stone*) which has reference to the resemblance of the measurements of the angles of the crystals to those of Chrysolite and other analogous minerals.

Tautology (Gr. ταὐτολογία). In Rhetoric, a vicious diction, by which the same idea is expressed in two or more different words or phrases, apparently intended to convey different meanings.

Tavernicus. The third great officer of state in the Hungarian monarchy (after the Palatine and the Ban of Croatia), analogous to the treasurer, and in some respects to the high chamberlain, of other European monarchies (Tavernicorum Regalium Magister). The origin of this purely Hungarian title has been the subject of much dispute. (Viroszil, *Staatsrecht des Königreichs Ungarn.*)

Tawing (A.-Sax. tawinn). The art of preparing certain kinds of leather by imbuing the skins with saline, oily, and other matters. [LEATHER.]

Taxaceæ (Taxus, one of the genera). A natural order of Gymnosperms, by some, however, regarded as a sub-order of *Coniferæ*, from which it is chiefly distinguished by the fruits not being collected in cones, and by each ovule growing singly, unprotected by hardened scales. The Yew-tree is the type of the group. [TAXUS.]

Taxatio Ecclesiastica. A name given to several public records. The oldest is that of Norwich, made in 1253, for the purpose of assessing the first-fruits and tenths of ecclesiastical benefices; sometimes called Pope Innocent's valor, that pontiff having made a present of these profits for three years to Henry III. All taxation was regulated by this assessment until the reign of Henry VIII., when the *Valor Ecclesiasticus*, sometimes called the *King's Books*, was compiled by his commissioners.

Taxation. In Political Economy, a tax is a contribution paid by the individual members of a community, with a view to supplying a fund out of which the general expenses of government, especially those which relate to the protection of person and property, may be duly liquidated. To the economist, the defence of taxation is to be found in the principle of the division of labour, and the advantages induced by such a division. Everyone would be prepared to admit that individuals, in the general interest of society, are not competent to interpret their own claims, to determine the extent of their own rights and wrongs, or, in justice or equity, to administer the law for their own sakes. But even were they able and willing to achieve such results, the economist argues that they could not do so as cheaply, as efficiently, and as continuously as a government, even when very imperfect, can do for them. It is true that sometimes an administration becomes so utterly depraved, or so rapacious, that society is disorganised, and men are obliged to take the protection of themselves into their own hands; or becomes so powerless, that its force has to be sustained or its negligence remedied by associations among private citizens. The first condition was exemplified towards the close of the Roman empire in the west; the latter in the organisation known under the name of the Vigilance Committee in the early history of the gold mining in California. Of course such expedients are desperate remedies, involving great waste of time and labour, a waste which those who feel constrained to adopt the measures thoroughly understand, and would gladly avoid by the payment of taxes, if it were only possible to secure the advantages of a just and vigorous administration. On the other hand, governments, however wise and well-intentioned, can seldom succeed in apportioning the burden of taxation on perfectly just and equitable grounds. It is the constant endeavour of good governments to effect such results, and in order to do so it

is necessary to lay down and generally follow certain definite rules.

History of Taxation.—In the early days of political civilisation, i. e. at the commencement of a system of responsible government, the machinery of the administration is simple, centring in one ruler, whose person is theoretically sacred, but who is liable to resistance, and in extreme cases to punishment for maladministration. Such a state of things characterised the feudal system, under which opposition to authority, insurrection, with the natural consequences to the losing side, the forfeiture of fiefs on the part of the vassal, and deposition or at least successful defiance when the monarch was defeated, were implied in the rights of defiance and private war. The occasions and process of these acts may be seen in Beaumanoir's *Customs of Beauvais*, ch. lix. lxvi. (Ducange, art. 'Diffidare.') To such theories we may trace the frequent revolts and insurrections which are to be found in our early feudal history. The doctrine that the king was irresponsible would never have been admitted down to the Restoration; and when the Revolution of 1688 formally established a constitutional monarchy, the theory that the king can do no wrong, originally an expression denoting his judicial equity, was transferred to his political status, and thereupon decorously evaded, by the rule that the king must be advised, but that his advisers are responsible for their counsel. In those days, then, all the proceeds of taxation were paid to the crown (cases in which a distinct appropriation of supply was made being treated rather as exceptions than precedents, such as some certain taxes paid in the reign of Richard II. and Henry IV.) and entered in the great Pipe Roll, along with other private and public sources of royal income. The efforts of parliament were therefore directed to the avoidance, not to the regulation of taxation, to stopping the supplies, not to their appropriation, and from the time of the Great Charter down to the Revolution, the limitation of the royal power was not unnaturally supposed to be connected with the scantiness of the royal revenue.

It appears (Hallam's *Constitutional History*) that the coldness which subsisted between William III. and his parliaments arose from the resolute determination on the part of the latter to make the crown dependent on the representatives of the nation. Thus they peremptorily resisted a favourite opinion of the king, that the large income which James had forfeited by his flight and by the action of the legislature was, eo ipso, vested in his successor. William knew very well that the resources of a monarch who exercised absolute authority over the means of war might be husbanded with far greater exactness, and employed with far greater effect, than those of which parliament superintended the expenditure. But the parliament had too bitter an experience of arbitrary government ever to let the privilege of control slip from their hands, even at the risk of some loss. We must remember, too, that the nation did not in William's reign enter into his large schemes of preserving the balance of power in Europe (a balance, by the way, of which he was the inventor); that it looked coldly on the policy which strove to check Louis XIV.; that it was by no means encouraged by the result of William's military measures, and did not heartily appreciate the prospect of acting as arbiter on continental questions, till after the splendid victories of Marlborough. But by this time the practice of appropriating the supplies had become a custom, and the parliament was the exponent of public policy.

The earliest English taxes were compositions for military service and levies on personal property. By the feudal rule, the military tenant was constrained to follow the bidding of his lord, and to take up arms at his discretion, whatever might be the distance of the expedition to be undertaken, and however unreasonable its object. In the reign of Henry II., whose dominions comprised nearly the whole seaboard of France, an arrangement was effected, by which the nobles were relieved from the obligation of taking their contingents to Toulouse, the price of the exemption, under the name of *escuage*, being fixed at twenty-five per cent. on the estimated rental of the knight's fee. The privilege of deciding the occasions on which this exceptional tax should be levied was accorded, by the terms of the Great Charter, to the parties who were to be made liable to the impost.

After the action of parliament, in the grant of taxes, was thoroughly understood, the chief source of extraordinary revenue was a property tax on chattels. This was granted by the House of Commons for the laity, by the Convocation for the clergy. The proportion varies greatly, from a sixth to a thirteenth, the larger nominal amount being granted by the clergy; but it was only nominally larger. It is clear that if the laity were taxed on all their movables, furniture, stock in trade, and even ready money in their possession, and the clergy on their tithes, that the tax was far more onerous in the former case, being on the capital of the former, on the income of the latter. This real inequality of taxation was a serious grievance, and provocative of great disaffection towards ecclesiastical privileges. The right of the clergy to tax themselves, an act which by some obscure process was necessarily confirmed by the House of Commons, was tacitly surrendered after the Restoration, in consequence, it is said, of a compromise entered into between Charles II. and Sheldon, archbishop of Canterbury.

Customs duties, as their name implies, are an ancient source of revenue. In the early history of England they were unimportant in amount, though sometimes export duties were onerous. It was believed that articles for which there might be a considerable foreign demand could be taxed without loss to the ex-

porter, and that the foreign consumer would really pay the charge. Nor were there any excise or internal duties. The origin of this latter class of taxes is to be found in the necessities of the two parties engaged in the contest between Charles I. and the Long Parliament. Excise duties were borrowed from the Dutch, who had been constrained during their long contest with the king of Spain to ransack every expedient with a view to discovering means for carrying on the war, and had consequently laid excise taxes on almost every article of internal consumption.

It was after the Restoration that the excise was formally and permanently established in England. The occasion of this great innovation was the necessity of devising some compensation to the crown for the loss of the feudal incidents affecting lands held by military tenure. Thus, for instance, the possessor of such an estate was liable to charges on descent and on alienation. In case he was succeeded by an infant heir, the rents and profits of lands during the heir's minority became the property of the crown, and were in the aggregate so considerable as to form the object for the investigations and procedure of a particular court called the Court of Wards and Liveries. These and similar imposts, though not productive of a very large income to the king, were vexatious and destructive to the lords, and, if they could not be totally abolished, needed reconstruction on a fair and intelligible basis. The most obvious compromise would have been a permanent tax in the shape of a fee-farm rent payable to the crown; and such a compromise was suggested in the reign of James I. But the first parliament of the Restoration achieved, by a majority of two (Nov. 16, 1660), and in spite of the energetic resistance of the members from the principal towns, the emancipation of their estates by the grant of the hereditary excise, i.e. they charged the whole nation of consumers with the liabilities to which they, the possessors of a certain portion of property, were subject. It is worthy of remark, that, while they freed their own estates at the expense of other people, they continued to retain, and still retain, their own rights as mesne lords over the estates of copyholders, who, being at that time unrepresented, had to submit in silence.

At the Revolution the proceeds of new customs and new excises were devoted to liquidating the interest, and, when the obligation was terminable, the principal, of new loans. If, as was often the case, the income from the tax was in excess of the annual sum demanded, the surplus was collected into a consolidated fund, and when fresh expenditure was needed the surplus income formed a basis for financial operations. Of course, in time, additions made to taxes ceased to be productive, partly because they were met by smuggling and frauds on the revenue, partly because consumption was checked by over-taxation. In short, as has been wisely observed, in the arithmetic of the custom-house two and two do not always make four. The practice of pretending to create a fresh income by an additional tax, and of affecting astonishment at the failure of such fiscal predictions, was carried to its height by Mr. Vansittart, whose absurd plans during his long tenure of office as chancellor of the exchequer had at least the merit of enabling more capable statesmen to realise the true theory of finance.

The duty of revising the customs and excise duties was urged, shortly after the peace, on the administration which held the reins of government for so long a period, and of which Lord Liverpool was the head. Timid at first, but still anxious to develope the resources of the country by removing the pressure of ill-advised taxation, successive cabinets have continued the work, until at present the revenue is derived from a very few articles; and the real questions left, on the understanding that the necessary charges of the state are to be procured in the least wasteful and onerous and most equitable manner, are chiefly those which bear on the respective merits of direct and indirect taxation, and those which attempt to settle the former on a fair basis.

The Principles of Taxation.—'The sting of taxation,' says Niebuhr, 'consists in wastefulness.' To this we may add inequality, unfairness, favouritism, and whatever else is included under the reproach of *class legislation*. The rules laid down by Adam Smith (*Wealth of Nations*, book v. ch. ii. part ii.) have become classical. 1. The subjects of every state ought to contribute towards the support of the government, as nearly as possible, in proportion to their respective abilities. 2. The tax which each individual is bound to pay ought to be certain, and not arbitrary. 3. Every tax ought to be levied at the time or in the manner in which it is most likely to be convenient for the contributor to pay it. 4. Every tax ought to be so contrived as both to take out and keep out of the pockets of the people as little as possible over and above what it brings into the public treasury of the state. In accordance with these rules, a financier should study *equity*, *certainty*, *convenience*, and *economy*, in the imposition of taxes.

Some difficulty has attached to the word *abilities* used by Adam Smith in his first canon of taxation. But it seems manifest that the author of the *Wealth of Nations* has explained his use by the illustration which he appends. 'The members of a community,' he says, 'are like the joint tenants of a great estate, whose contributions are relative to their respective interests in the estate. From this point of view, as the interests must be estimated according to the value of each share, equity in taxation according to abilities must be proportioned to the capital value of each man's property in the state, whether that capital be represented in objects external to him, or invested, so to speak, in himself; whether, in short, it be property or skilled labour.' It will

be observed that Smith does not recognise the principle which has been occasionally advocated, that, namely, which holds the liability to taxation to be relative to the protection accorded by the state—a rule which, if admitted, would consistently levy the heaviest taxes on women, children, and others who are least capable of protecting themselves.

Granted, however, that taxation is fairly apportioned, or at least as fairly as can be effected by the ingenuity of financiers, the main rule is that which provides that as little loss as possible shall be involved in the collection of the tax. To effect this result, the least possible time should be interposed between the levy of the tax on the article consumed (if the tax is a duty on goods) or used (if it be an article representing fixed capital). Again, if the collection of the tax involves a number of minute details, the cost of collection may become disproportionally large; or if the producer of the article upon which the tax is levied is subjected to vexatious supervision, the manufacture may be abandoned altogether, or the price of the article may be unduly enhanced.

It is easy to illustrate irregular and wasteful taxation from the records of financial history. Nothing could have been more unwise than the policy of the government of this country till within the last twenty years. For instance, up to within a comparatively short period, a customs duty was levied on raw cotton, an excise on printed calicoes. No tax can be worse than that which is levied on a raw material, because, as a portion of the capital of the manufacturer is absorbed in paying the tax, and as this portion must secure a profit, and be insured against risk, not less than that which is employed in the purchase of the raw material and the advance made for the wages of labour, and as this tax is levied at or before the commencement of the process, it will ramify through all the stages of the manufacture, and appear as an accumulated impost to the consumer, the amount thus paid being far in excess of that received by the exchequer. Furthermore, it is grossly unfair, being much more heavy on cheaper than on dearer stuffs. Nor can it easily be compensated when the same article may be imported from foreign countries, in which no such tax exists, except by a duty which is almost prohibitive. And as raw materials are generally imported from countries which take manufactured goods in exchange, such a tax, as it diminishes consumption by an import unduly enhanced, seriously impairs or contracts foreign trade. The same objection applies to taxes on food, which are in effect taxes on the raw material of human life. These taxes have this evil in addition, that they contribute to the exchequer only from that which is imported, while they mulct the public in all which is consumed.

The excise on printed cottons was mischievous on other grounds. Of course it checked consumption. But it did so in consequence not only of the enhanced cost which the tax involved, but of those hindrances to improvement which excise regulations, being of the character of a detective police, invariably create. The principal part of the direct loss involved in the excise lay in the fact that the duty paid on the conclusion of the manufacture was affecting the price up to the time in which the goods were sold, and, in case the goods were long in sale, formed a notable part in the risk of the undertaking. Nothing, in effect, could have been more striking than the consequence of repealing the excise duty. In a short time, notwithstanding the enormous profits of the manufacturers and the printers of cloth, the price of printed calicoes, by the mere force of competition and improvement in the process of manufacture, actually fell below the amount which had previously been paid for the excise. It is hardly necessary to say that this cheapness operated indirectly in a multitude of ways to the benefit of the revenue, by increasing the powers of consuming, duty-paying, and excisable commodities on the part of both manufacturers and factory hands.

Another instance of the effects of an excise on a raw material (not, however, suffered except indirectly, and in the form of insurance against risk, by the consumer, but chiefly by the producer) was found in the excise on hops. The cultivation of hops was essentially a gambling transaction. The demand for hops is, on the whole, even, year after year. The quality of the article is best when it is just prepared, and it rapidly deteriorates by keeping. Hence the effect of the excise duty was mischievous in the last degree. If the crop were abundant, the cultivator was ruined, or at least seriously mulcted, by the magnitude of the tax, and the fall in the value of the produce. If, on the other hand, the crop was scanty, the value of it fell below the cost of production. The hope of the hop farmer lay in an average crop. It was an indirect feature in the incidence of the excise that it stimulated the habit of gambling. Nothing was more common than the practice of staking great sums in bets on the amount of the hop duty.

At present all taxes on raw materials are abolished: the last, and one of the most objectionable—that on timber—having been repealed in the budget of the present year (1866).

The Incidence of Taxation.—It does not follow that a tax is really paid by the person from whom it is actually received. He may be the mere channel through whom the payment is made. Many a person thinks he pays taxes, and acts on the supposition, when he is a mere agent for others. This fact may be readily illustrated. A tax, for example, on rents is paid by the landowner. There is no means by which he can shift the tax from himself to others. Similarly, if any tax is paid, no matter by what person, which reduces the power or the inclination of such a person to pay rent, the tax is really paid by the landowner, since, as we have seen above [RENT], rent is what remains after the capitalist and labourer are recom-

pensed from the produce. Thus, a tithe-rent charge is paid not by the farmer, but by the land-owner. It is manifest that, were the tithe abolished, rents would rise, and the rent charge would be transferred from the parson to the landowner, as is virtually the case when lands are tithe-free. But, on the other hand, a poor-rate, in so far as the landowner is directly or indirectly an employer of labour, does not fall on the landowner at all. It is in such a case, even were he to pay all the poor-rate, merely a displacement of a part of wages—an insurance fund paid from wages, for if the aid of the poor-rate were not granted to the labourer, wages would inevitably rise by at least the whole amount of the rate, and probably to a greater extent; and in so far as the poor-rate is paid by those who are not employers of labour, the tax is a direct relief to the landowner or the employer of labour, who gets labour at lower rates, because a portion of the poor-rate, which is, economically speaking, the *fund devoted to the insurance of labour*, is paid by other persons.

Again, an income-tax paid from fixed sources, as the rent of land, the profits of stock, and, generally speaking, from the revenues of those who cannot raise or depress the amount of their income, is paid by those who contribute it. But it does not follow that an income-tax derived from the profits of business is paid by the trader. He may, and probably does, compensate himself for the increased cost at which he is compelled to carry on his business by increased rates on the goods in which he deals, and this even when his business is exposed to competition. In such a case, the payment made by the recipient of a fixed income may contain not only his tax, but the tax of others, indirectly laid on him. Nor is it possible to evade this displacement by the machinery of any income-tax, though it may be by a property-tax, for the utmost which such an impost could effect would be a discouragement to accumulation. But this discouragement is a very remote hypothesis.

So a license on trade or practice, though seemingly paid by the licensed person, is really paid by the public. The tendency of profits and wages, cæteris paribus, is towards an equality. No man, however, will voluntarily put himself under a disadvantage, and if he can shift it where it is imposed, he will do so. A license, then, is similar in character to a tax on raw material: it multiplies itself, and causes far more loss than it reaps of profit. Sometimes, indeed, it may affect more parties than one. Thus, the tax on male servants is confessedly a check on the employment of such persons. It probably affects employers, and it certainly is a hindrance to some kinds of labour. The tax, on principle, is wholly indefensible. Again, an excise duty on malt, if indeed it affects agriculture unfavourably and prevents the cultivation of barley, is a tax on rents as well as on consumers. If it does not, it is a tax on the consumers of beer only. Nothing but the most inveterate stupidity could interpret the malt-tax as a tax on farmers. It may be a mischievous form of taxation, but it cannot be any special grievance to tenant farmers. It is perfectly certain that many worse taxes exist, the repeal of which is far more urgent.

One of the most notable among unfair taxes, some time ago repealed, was the tax on goods sold by auction. If all sales were visited with a pro ratâ tax, the measure, though a gigantic act of folly and waste, would be fair. But a tax on auctions is in the last degree unjust. In the first place, it was exceptional, and in the next, it was levied on sales which, in nine cases out of ten, represent poverty and distress. When the tax was repealed, the opposition to its erasure from the statute book was very strong, on the common but very foolish plea that a repeal of taxation cannot be attempted in the face of a deficit or an apprehended deficit. Similar in principle, and almost as indefensible, are the enormous taxes levied on mortgages. They would be less unfair if equal or analogous imposts were laid on all loans, or contracts for capital.

Much needless labour has been expended on deciding whether particular taxes are levied on profits or capital. Thus, on the hypothesis that taxes on capital are inexpedient, Ricardo argued that legacy duties were mischievous. In the opinion, however, that a legacy duty is a bad tax, this author stands almost alone. If there be any case in which an impost can be fairly laid, it seems to be in the instance of transmitting property on which the recipient has devoted neither labour nor capital of his own; and the graduated tax on the devise of personal property, though not quite just, is, perhaps, sound in principle and fairly equitable in practice.

In point of fact, the question whether property is capital or income is settled by the individual. As a rule, it is no doubt the former, but it lies with the discretion of the recipient whether it should not be the latter. If a man spends a legacy, he makes it part of his income; if he invest it, it is part of his capital, and if he be resolved to invest it, it is not easy to see, after the first charge which a government may put upon it, how such capital may, if financial expedients be even ordinarily equitable, be subject to taxation at all. It is possible that capital may be taxed; it is taxed by the practice of the income-tax, but this tax cannot be defended on any rational plea, since the charge on the profits of fixed or destructible capital is levied at the same rate as that on floating or permanent capital.

All taxation is, no doubt, an evil. But it is to the person who pays the tax, not necessarily to the community. It curtails the power of enjoyment possessed by individuals, and as individuals may fairly be acknowledged to have

the right of enjoying the fruit of their labours, any diminution of their enjoyments can be justified only on the ground of their ultimate advantage, or the common good of society. If any man pays a tax, he has so much less to spend for his own purposes; but he should, and in all well-administered governments he does, understand that the diminution of resources to which he must submit gives him larger and more convenient powers over the remainder.

But it does not follow that the loss to the individual may be a loss to the community. For instance, suppose a government levies a tax the effect of which on A is to deprive him of the power of buying a picture, and on B of obliging him to buy one picture a year less, and, with the proceeds of the tax, hires soldiers. The demand for pictures may be diminished, and, pro tanto, the labour of the painter may be discouraged. But general labour is benefited, partly in the diminution of labourers consequent on the demand for soldiers, partly by the competition for the supply of maintenance to such soldiers. And if the proceeds of the tax are devoted to really productive objects, as building a bridge, digging a canal, forming a road, laying out a railway, and the like, the general community may be greatly benefited by such a tax, and, after all, the person who pays it may not be absolutely mulcted.

Capacity for Taxation.—Taxation does not necessarily form a hindrance to the energies of a nation. Nothing could have been more onerous than the taxes laid on the Dutch during their war of independence. But Holland, even under this pressure, became in spite of great disadvantages the wealthiest community in Europe, contesting, and for a long time with great success, the empire of the seas; and it lost its mercantile and political supremacy, not from the pressure of its financial difficulties, but through its obstinate adherence to a mistaken commercial policy. After the peace of 1815, when the tariff of this country was constructed on principles which utterly defied all common sense, the elasticity of trade, and the energies of the people, favoured to some extent by the fact that other governments were even more unwise than our own, enabled the nation to make astonishing progress. What that progress might have been, had it never been hindered by the policy of Mr. Vansittart and Lord Castlereagh, may be conjectured from the progress made since that policy has been abandoned.

The capacity for paying taxes is, on the whole, measured by the margin over and above their necessary expenditure which remains to the mass of the community. Unless all taxes are raised directly from income and profit, a state of things which has never been realised in practice, and only faintly suggested in theory, indirect taxes, in order to be collected at a moderate charge, must be levied on articles of general consumption, i.e. on such secondary necessaries of life, or ordinary luxuries, as are enjoyed by the mass of the people. This, it is notorious, is the case with the financial system of this country, the revenue of which, as derived from customs and excise, amounted to nearly forty-one millions in the last financial year. Of this sum, by far the largest amount was derived from the contributions of those who are inaccurately called the *working classes*, but who would be more exactly described as persons possessing less than 100*l.* a year of annual income.

In the United States, the margin available for taxation is far larger, as the rate of profit and the rate of wages are higher, and the rent of land is low. Hence financial difficulties which might stagger other communities would be easily borne by that republic. We know, in our own country, that, owing to reforms in our commercial policy, taxation which used to be intolerable has become comparatively easy, while in the United States the all but unlimited resources of the soil and the energy of the inhabitants are sufficient to countervail that mischievous adherence to a protective system, which cripples the energies and discredits the intelligence of the American people. Countries, in short, in which the mass of the people is impoverished, however gorgeous and imposing may be the wealth possessed by a few, are poor, weak, and unable to meet the exigencies of a large public expenditure; while, on the other hand, those communities in which wealth is abundantly distributed, and in which comfort and comparative affluence are shared by most members of the society, are capable (not only for political, but for economical reasons) of supplying, with but little privation, abundant means for the necessities of government.

Protective Taxation.—We have already [PROTECTION] commented on the arguments alleged in favour of protection, and the refutation which has been conclusively directed against these arguments. At the present time, the policy of our government has professedly been to treat all taxation as a question of revenue, and to ignore any effects which it may have on stimulating or supporting domestic industry. It is intended that every article of home or foreign production or manufacture should be put on the same level, and that no favour of any kind should be shown. As a rule, the principle is sustained, though there is still one notable exception. If the object favoured by a protective arrangement is a manufacture, the consumer invariably pays more for a worse article; if it be a necessary of life, he pays the duty on all that is consumed of it, the state obtaining a revenue only on that which is imported. Thus, although at the repeal of the corn laws only a shilling duty was retained on grain, yet as, even when the harvest is most abundant, considerable quantities of foreign corn are always imported, the whole amount of grain sold is raised by the shilling tax, this tax being on an average about 2½ per cent. on the value. This 2½ per cent. is a bonus to the landowner, and is appropriated by him naturally in the shape of rent. The amount of indirect aid thus accorded to landowners has been reckoned on an

average at 4,000,000*l.* per annum, the amount raised as revenue being under 400,000*l.*

Import and Export Duties.—It has been already stated that a considerable part of the revenue of this country is raised by customs on six principal articles, tea, coffee, tobacco, sugar, corn, and alcoholic fluids. Of these, the largest amount is derived from sugar and tobacco, which together contribute more than half the customs duties. These taxes may be said to be paid for the most part by the poorer classes, who are the great consumers, by virtue of their numbers, of the commonest luxuries and the most familiar among the secondary necessaries of life. The tax on tobacco, though enormous, does not seem to provoke much smuggling; and on the hypothesis that all members of the community ought to contribute to the exigencies of the state, no two taxes, it seems, could have a fairer incidence on consumption than these.

No community whose system of finance is managed with the commonest reflection imposes an export duty on its productions. It sometimes appears, however, to the administration of particular communities, that there are commodities in which it possesses peculiar advantages. Such, for instance, was wool to our forefathers, such is sulphur to Sicily, such was cotton to the Southern States of the American Union. Now, under such circumstances, it is common for governments to imagine that an export duty will be paid by the consumer. But the impression is a delusion, and the action consequent upon this impression is sure, at no remote period, to destroy the peculiar advantage possessed by the community in question. If, indeed, the article were an absolute necessary of life, if it were obtained in one region only, and the administration of such a region could completely control the supply, it would be possible to levy a general tribute on the whole world by the imposition of an export duty. But there is not, and, as a little reflection will show, there cannot be, any such commodity; while, if there should be an accidental advantage, the attempt to control the market is sure to be met, and successfully obviated, either by obtaining a supply from other regions or by the substitution of some other article. The English government prohibited the importation of colonial sugar into France during the continental war. At that time this country had a complete control over the supply of this tropical produce. The result was the establishment of a manufacture of sugar from beet. It adopted the same policy with saltpetre, then derived entirely from India. A successful home manufacture was rapidly developed. The Sicilian government attempted to control the export of sulphur, an absolute necessary for the manufacture of sulphuric acid. The material was obtained from pyrites. Instances might be multiplied to prove how futile is every attempt (whether it be for fiscal or for military purposes) to control the consumption of foreign countries, or to levy an indirect tax on them, by any regulations intended to prohibit exports or to render them a source of revenue.

Local Taxation.—Accounts given of the annual revenue of foreign countries generally include a portion of income which is omitted in the statement of our own expenditure, and omit an item which is formally contained in that of Great Britain. Both the omission and the inclusion are due to the fact that in this country there is a perpetual tendency 'to decentralise,' a term by which continental nations express the attempt to leave as wide a range as possible to the free action of individuals, to municipal or local activity, to what, in short, we call self-government. Thus the various local taxes, such as the poor-rate, the highway, county, and police rates, the charges for municipal management, lighting and paving, &c., are not included in the general budget, because they are locally imposed and locally administered, whereas in most foreign countries they are under the control and distribution of a central bureau. On the other hand, part of the charges which belong to the department of the army in this country, the cost, namely, of recruiting, is met in other countries by the system of conscription, or militia.

It is by no means easy to give any exact account of local taxation. The aggregate of poor and county rates in England is nearly ten millions annually, the former of these two items varying but little, the latter rapidly and steadily increasing. In Ireland and Scotland, the sums expended on the relief of the poor are nearly the same, about three-quarters of a million in each kingdom. But there are many other local charges evidence of which is deficient. Perhaps the amount would not be over-estimated at fifteen millions.

By far the greater part of this taxation is immediately returned to those who pay it, or at least to some of those who contribute to the fund. We have shown above [PAUPERISM] that a poor-rate is an indirect way of paying wages, and that, in the absence of such a rate, wages would inevitably rise. So, again, a road-rate is only a means by which every person who makes use of a road is called on to contribute towards its maintenance; a contribution which is unfairly and wastefully levied when it takes the shape of a toll, collected at a gate: unfairly, because many persons use the road, and use it very roughly, who do not pay the toll; wastefully, because the receipt of the toll is burdened with a great charge in collection. It would be both just and expedient if all tolls taken for public services were commuted into general rates, and apportioned according to assessment or property possessed or occupied within the region which gets the benefit of the service.

Direct and Indirect Taxation.—By far the largest portion of the public revenue in this country is obtained from indirect taxes, i.e. from taxes levied on commodities to be consumed, and not on income or the power of consumption. By the machinery of bonded warehouses, the

incidence of indirect taxation is made as light as possible, and, by a judicious tariff, the temptations to smuggling and similar illicit practices are greatly diminished. Public opinion, in short, has powerfully supported government in checking frauds on the revenue, because it has been felt that, in the assessment of customs duties, the ends of the government have been intelligible, and its administration honest. High duties, no doubt, stimulate smuggling: but oppressive, capricious, or interested taxation does so in a far greater degree. Nor can it be said that the system of indirect taxation checks commercial enterprise, or hinders England, in the language of those who favour direct taxation, from becoming the free port of the world.

Of late years attention has been constantly called to the merits of these rival methods. It is urged that direct taxation could be levied with greater economy, and that, its incidence being felt more keenly than that of indirect taxation can be, there would be a more watchful supervision over public expenditure. It is also said that direct taxation is fairer than indirect. But it is hardly conceivable that an absolutely direct system of taxation (embracing, in order to be equitable, all incomes, however small) could be carried out at all, or, if carried out, could be effected at small expense, unless every man who paid wages, or bought commodities, were constrained to be a tax-gatherer. Nor, to judge from present experience, does it seem likely that this keen insight into public expenditure would ensue from direct taxation. Almost all local taxation, amounting on the estimate given above to little less than a fourth of the imperial taxation, or, setting aside the interest of the debt and the immediate charges of government, to nearly half the imperial taxation, is obtained directly; and yet perhaps no portion of the moneys which individuals pay for public purposes is under less control, supervision, and criticism, than is this local taxation.

Nor, if we are to argue from the principle on which the income-tax is assessed, and assume that this principle should form the basis of all taxation, would much be done by way of equity. There are very few persons who are not convinced that the income-tax is other than unfair and unequal, although as yet the true principle of such a tax has not been allowed, nor, were it proved, is it likely that it would be accepted. In short, the arguments alleged by those who are called financial reformers, and who declare that all indirect taxation should be abandoned in favour of a direct system, are, we may admit, theoretically sound, but demand a higher moral tone, and perhaps a larger amount of economical reasoning, than the present state of society possesses, or is capable of comprehending. It is certain that, among existing direct taxes (to omit the income-tax, the strongest example of unfairness), those which are levied on successions, with the irrational distinction between real and personal property, on conveyances, and on insurance, where an equally irrational distinction is made between farming stock and other property, are the worst and most flagrant examples of one-sided legislation.

Taxicornes (Lat. taxus, *a yew-tree*; cornu, *a horn*). The name of a family of Coleopterous insects, including those in which the antennæ gradually increase in size as they extend from the head, or terminate in an enlargement.

Taxidermy (Gr. τάξις, *arrangement*, and δέρμα, *skin*). The art of arranging and preserving the skins of animals. The most popular treatise on taxidermy is Mr. Swainson's volume in *Lardner's Cyclopædia*.

Taxis (Gr.). In Surgery, the replacement of parts, which have quitted their natural situation, by the hand, and without instrument or operation; as in reducing hernia or rupture.

Taxodium. A genus of *Coniferæ*, of the tribe *Cupressineæ*, consisting of lofty trees, inhabiting for the most part the rich swampy soil of Florida and other Southern States of North America. The Deciduous or Bald Cypress, *T. distichum*, is an ornamental tree commonly seen on lawns and in similar situations, where its feathery foliage renders it an attractive object. In its native country its bark and wood are much used for covering houses, for thin planks, ribs of ships, water-conduits, and other purposes. The roots sometimes bear large hollow excrescences, which are made use of by the negroes as beehives.

Taxus (Lat. *the Yew-tree*). The Common Yew, *T. baccata*, is a well-known evergreen tree, characterised by a trunk peculiarly suggestive of massiveness and solidity, not being covered, like the trunks of most other trees, with a splitting bark, but seemingly composed of a number of smooth stems fused together, and sending out numerous horizontal branches, which spread in all directions, and are densely clothed with tough twigs, on which the numerous leaves are thickly set on opposite sides. The flowers are of two kinds, and grow on separate trees. The fertile flower resembles a minute acorn, the cup of which swells, and, when ripe, has the appearance of red cornelian, enclosing a small oval brown nut, the summit of which is uncovered. These fruits drop when ripe, and contain a sweet glutinous juice of a mawkish disagreeable taste, but are eaten with impunity by children, and are greedily devoured by wasps, moths, and several kinds of birds. The leaves are poisonous, though to what extent is a disputed question; but there can be no doubt that their effects on the human frame are deadly, and that to allow cattle to eat them is a perilous experiment. The poison appears to be more virulent in the young shoots than in any other part of the tree, but exists, in greater or less quantities, both in the fully-expanded leaves and in the green bark. The leaves are more dangerous in a half-dry state than when fresh. 'Yew-tree tea,' an infusion of the leaves, is, according to Dr. Taylor, sometimes used by the poor and ignorant for

the same purposes as savin, but with equal danger. The wood is hard, compact, of a fine and close grain, elastic, and incorruptible, of a fine orange-red or deep-brown; the sapwood being white and also very hard. The fineness of its grain is owing to the thinness of its annual layers, the Yew-tree being of exceedingly slow growth; 280 of these layers are sometimes found in a piece not more than twenty inches in diameter.

The Yew is a native of most of the temperate parts of Europe and Asia, and is generally found growing in a clayey, loamy, or calcareous soil, which is naturally moist. Yew-trees of great antiquity and large size are often to be met with in old churchyards, but from what motive they were planted in such situations is not clearly ascertained. Some of the various reasons assigned are, that the poisonous foliage of the yew typified death; that its durability and slowly-altering features symbolised the Resurrection; that it might afford a supply of twigs to be worn on Palm Sunday;—from a still more utilitarian point of view, that there might be always at hand a supply of wood for making bows. Yews are in existence which are supposed to be above a thousand years old. The dimensions of the largest range from thirty to upwards of fifty feet in circumference.

Taylor's Theorem. This important theorem was first given by Brook Taylor in his *Methodus Incrementorum*, Londini 1715; it furnishes, whenever possible, the developement of a function $F(x+h)$ in ascending powers of h. Lagrange, as is well known, proposed to found the whole differential calculus upon Taylor's series; its want of generality, however, has been justly urged as an objection to such a proposition. Besides Taylor's own proof of his theorem, others have been given by Maclaurin and Stirling, D'Alembert and Cauchy, Lagrange, Ampère, and others. In all treatises on the calculus, one or more of these proofs will be found; we shall, therefore, simply give the theorem, and refer the reader to such sources for further details. Denoting by $F^{(i)}(x)$ the i^{th} derived function of $F(x)$, we have—

$$F(x+h) = F(x) + \frac{h}{1}F'(x) + \frac{h^2}{1.2}F''(x) + \ldots + \frac{h^i}{1.2\ldots i}F^{(i)}(x) + R_1,$$

which is true when neither $F(x)$ nor any of its derived functions become infinite for values of x between which the theorem is employed. The *limit*, *residue*, or *remainder* R_1, which it is always necessary to add in order to render the formula exact, may be expressed thus—

$$R = \frac{h^{i+1}}{1.2\ldots(i+1)}F^{(i+1)}(x+\theta h).$$

Cauchy's equivalent form is—

$$R_1 = \frac{(1-\theta_1)^i h^{i+1}}{1.2\ldots i}F^{(i+1)}(x+\theta_1 h),$$

and in both θ and θ_1 are *proper* fractions. Employing a definite integral, this residue may be thus exhibited—

$$R_1 = \frac{1}{1.2\ldots i}\int_0^h z^i F^{(i+1)}(x+h-z)dz.$$

When $F(x)$ is a rational and integral function of the n^{th} degree, R_1 will be 0, and the series will end with the $(n+1)^{th}$ term. If it can be proved that R_1 vanishes when i is increased without limit, then $F(x+h)$ may be expressed by the corresponding infinite series, provided the same be convergent. It is necessary to bear in mind, however, that the converse is not necessarily true; the infinite series may be convergent, and still not represent the value of $F(x+h)$, since R_1 may not vanish; hence the necessity of taking the residue R^i into consideration. In such cases Taylor's theorem is said to *fail*.

Taylor's theorem may easily be extended to functions of two or more variables; the result, however, is most conveniently expressed in the symbolical form. To illustrate this, let the symbols of operation and quantity in Taylor's theorem be separated. We may then write it thus—

$$F(x+h) = \left(1 + h\frac{d}{dx} + \frac{h^2}{1.2}\frac{d^2}{dx^2} + \&c.\right)F(x)$$
$$= e^{h\frac{d}{dx}}F(x).$$

The expression $e^{h\frac{d}{dx}}$ is purely symbolical, and acquires a meaning only when developed as if $h\frac{d}{dx}$ were a symbol of quantity. Similarly, in the case of two independent variables, the operative symbols $\frac{d}{dx}, \frac{d}{dy}$ being commutative, and combining with each other, and with constants, in precisely the same manner as if they were symbols of quantity, the symbolical equation $e^{h\frac{d}{dx}}e^{k\frac{d}{dy}} = e^{h\frac{d}{dx}+k\frac{d}{dy}}$ may be easily verified.

And thence we may deduce the expansion—

$$F(x+h, y+k) = e^{h\frac{h}{dx}}e^{k\frac{d}{dy}}F(x,y)$$
$$= e^{h\frac{d}{dx}+k\frac{d}{dy}}F(x,y)$$
$$= \left[1 + \left(h\frac{d}{dx} + k\frac{d}{dy}\right) + \frac{1}{1.2}\left(\frac{d}{dx} + k\frac{d}{dy}\right)^2 + \frac{1}{1.2.3}\left(h\frac{d}{dx} + k\frac{d}{dy}\right)^3 + \&c.\right]F(x,y).$$

The extension to functions of any number of variables is now manifest.

Tchingtchang. The Chinese name for dark-blue Lapis Lazuli containing spangles of Iron Pyrites.

Tchornozem. The name locally given to a singular but very important black earth covering at least a hundred million of acres of country extending from the eastern foot of the Carpathians to the Ural Mountains,

and having a thickness sometimes amounting to twenty feet. It is at various elevations, but its composition is the same everywhere. It contains 75 per cent. of silica, 9 per cent. of alumina, about 7 per cent. of decaying organic matter, with an unusual proportion of nitrogen gas and very little lime. More than 5 per cent. of oxide of iron is often present. Among the many rich soils in various parts of the world, none are more remarkable than this for the number of similar crops that can be obtained in succession without the smallest preparation or precaution. The nitrogen and organic matter contained in it are, no doubt, the great causes of this fertility, but the mechanical state of the soil is an important adjunct.

Te Deum (from the first words of the original Latin, 'Te Deum laudamus,' *We praise Thee, O God*). The authorship of this hymn has been ascribed by some to Ambrose and Augustine; by others to Ambrose alone, to Hilary, and to other less distinguished persons. It is, however, generally thought to have been composed in the Gallican church: the most ancient mention of it being in the rule of Cæsarius, bishop of Arles in the fifth century. The Te Deum, in the office of matins, is always sung after the reading of Scripture; in the English morning service, between the two lessons. (Palmer, *Origines Liturgicæ*, ch. i. part i. sec. ii.)

Tea (Chinese tcha or tha). The popular name of the plants belonging to the genus Thea, which yield the tea of commerce.

Various plants, possessing, in some part of their structure, peculiar stimulating and sedative properties, and acting, in medical language, also as emulgents, have long been employed, when infused, as a beverage. Chemical analysis detects the same or a similar principle in the leaves of the tea-plant, in the berries of the coffee, in the bark of the *Ilex paraguayensis*, and in the Peruvian coca. Of these, the best known to us are tea and coffee, the former having been used time out of mind by the Chinese.

The Chinese names given to the different teas are usually derived from their appearance or place of culture. Thus Souchong, or Sian Chung, means *little plant*; Hyson, from Yu Tsien, *before the rains*, or Hichun, *flourishing spring*, from the fact of the leaves being gathered early; Pekoe is from Pecco, *white hairs*, because the very young leaves from which this tea is made have a white down upon them; Bohea is derived from the Bw-i Hills, where this tea is produced. (*Quarterly Review* 1864, part ii. p. 22.)

The name Tea is also applied to the dried leaves of various plants, and to the infusions prepared from them, and used either as beverages or medicinally. Of these the chief are: Abyssinian or Arabian tea, prepared from *Catha edulis*; Australian or New Zealand tea, obtained from several species of *Leptospermum* and *Melaleuca*; Faham or Bourbon tea, obtained from *Angræcum fragrans*, an infusion of which is drunk to promote digestion, and the odour of which is owing to the presence of coumarin: Labrador tea, obtained from *Ledum latifolium*; New Jersey tea, the produce of *Ceanothus americanus*; Paraguay tea, obtained from *Ilex paraguayensis*; South-Sea tea, obtained from *Ilex vomitoria*; and Theezan tea, obtained from *Sagaretia theezans*.

Tea was not known in England till the close of the seventeenth century. But its use was fully established by the middle of the eighteenth century. Tea is enumerated among excisable articles in the year 1660, the form of the duty being 8*d*. a gallon on the infusion supplied in coffee-houses, commuted to an excise of 5*s*. the lb. in 1689. In 1667, the East India Company directed their agent at Bantam to purchase 100 lbs. of the best tea that he could find. In 1711, the quantity consumed in England was nearly 150,000 lbs., the retail price being very high: domestic account-books, still preserved, often recording purchases at from 17*s*. 6*d*. to 20*s*. the pound. In the time of Arthur Young, about 1770, the consumption had increased to 7,000,000 lbs., and this writer laments, throughout the records of his agricultural tours, that the peasantry had abandoned the use of the national beverages and taken up with tea.

The chief consumers of tea are the English, the Dutch, the Americans of the United States, and the Russians, the importation in the first three cases being effected by a sea passage, in the last by caravans. It is said that tea carried on sea always loses a portion of its flavour, and that the finest qualities are found in Russia. Tea reaches us in chests, and in the well-known form of dried and rolled leaves. Much, however, of that which is imported to Russia is pressed into cubical masses, and is known as brick tea. This is the form in which it is most frequently found in Central Asia. (See the travels of Huc and Gabet, Atkinson, and Vambéry.)

The chief source of tea is China, where it is cultivated over a vast district between the twenty-fifth and twenty-third degrees of latitude. It is also grown in great quantities in Japan, in latitudes at least ten degrees north of the China districts; and teas of excellent quality are coming into the market from these islands. It is an increasing object of agriculture in the Eastern Himalayas, particularly in Assam, the produce of which bears a higher average price than that of any other locality. There is nothing, except the cost of labour, to interfere with the production of tea over the whole coast of the Mediterranean, for the tea-plant is a hardy evergreen, which can withstand the cold up to at least the fortieth degree of latitude.

Teas of the finest quality are, like wines, the growth of particular districts, and even of particular estates, the best kinds being prepared with extraordinary care, and selected with great exactness. The gardens and small

plantations in which the tea is grown and prepared are visited by regular purchasers, who collect the produce in order to forward that which is intended for the foreign market to the various ports frequented by Europeans. The finest packages are marked with a particular stamp, called a *chops*, a Chinese word said to signify a seal. The agents, through whose hands alone foreigners could make their purchases, were formerly known as the merchants of the Hong, and it is stated that the commercial credit of these merchants was held in the highest estimation.

Up to the year 1834 the trade in tea was the monopoly of the East India Company. This monopoly was, as our readers are doubtless aware, the proximate cause of that outbreak at Boston in the year 1770 which led to the independence of the United States. The privilege was exceedingly oppressive to the English public, and of little or no value to the company. It was stated in 1830, only four years before the abolition of the company's monopoly, that the cost of protecting the tea trade had been so great as to leave absolutely no profit. It was estimated, however, that the annual loss of the public in consequence of the company's monopoly was not less than 600,000*l.* or 700,000*l.* per annum. The abolition of the privilege was therefore passed in 1833 almost by acclamation.

The duties on tea were originally ad valorem, and calculated on the company's sales. After the abolition of the company's monopoly, the duties were paid at rates varying from 1*s.* 6*d.* to 3*s.* But the discriminating duties worked ill, as, indeed, such duties always do, and in 1836, an equal duty of 2*s.* 1*d.*, increased in 1840 to 2*s.* 2½*d.*, was substituted. In 1854, a set of new duties was fixed, on a gradually reducing scale, to commence, in 1854, at 1*s.* 10*d.*, to go on from April 1854 to April 1855 at 1*s.* 6*d.*, from April 1855 to April 1856 at 1*s.* 3*d.*, and to become 1*s.* at the latter date. The Crimean war disturbed this arrangement; the duty was raised to 1*s.* 9*d.*, and was reduced in April 1857 to 1*s.* 5*d.* In 1863 the duty was reduced to 1*s.*, in 1865 to 6*d.*

The two kinds of tea, black and green, do not differ generically, being merely varieties of the same plant. The plants are picked four times in the year, the finest kinds being the leaf-buds collected in the spring, called *pekoe*; the poorest that gathered in the autumn, and known as *bohea*. Green teas are occasionally faced with indigo, Prussian blue, and other drugs; but it does not appear that adulteration is carried on largely in China. It is said that frauds are practised in this country, by mixing sloe and ash leaves with tea, or by unrolling and dyeing tea-leaves which have already been infused. An Act of 4 George II. (so early were these dishonest practices commenced) prescribes a series of penalties for these offences.

The following tables give: (1) the imports of tea for the last ten years; (2) its value; (3) the price per pound of the principal kinds of tea in bond at London, for nine years:—

Years	Lbs.	£
1856	86,100,404	5,248,834
1857	64,493,987	4,677,470
1858	75,432,535	5,206,618
1859	75,077,451	5,812,545
1860	88,946,532	6,911,943
1861	96,577,888	6,850,562
1862	114,787,361	9,175,940
1863	136,806,321	10,666,017
1864	124,359,243	9,438,760
1865	121,271,219	10,044,462

Years	China	Assam	Japan
	Per Lb. *s.* *d.*	Per Lb. *s.* *d.*	Per Lb. *s.* *d.*
1856	1 2⅛	2 4¾	—
1857	1 5⅛	2 1¼	—
1858	1 4½	2 0	—
1859	1 6½	2 0	1 6
1860	1 9⅝	1 9	1 6
1861	1 5	1 9⅛	1 5
1862	1 8 3/16	1 9	1 7
1863	1 6⅝	1 11⅞	1 5⅝
1864	1 6	2 3	1 3¾

For further particulars, see *Commercial Dictionary*, art. 'Tea.'

Teak or Indian Oak. The produce of the *Tectona grandis*, a large forest tree, which grows in dry and elevated districts in the south of India, the Burman Empire, Pegu, Ava, Siam, Java, &c. Teak timber is one of the best in the East; it works easily, and, though porous, is strong and durable; it is easily seasoned, and shrinks very little; it is of an oily nature, and therefore does not injure iron. Mr. Crawfurd says that, in comparing teak and oak together, the useful qualities of the former will be found to preponderate. 'It is equally strong, and somewhat more buoyant. Its durability is more uniform and decided; and to insure that durability, it demands less care and preparation; for it may be put in use almost green from the forest, without danger of dry or wet rot. It is fit to endure all climates and alternations of climate.' (Tredgold's *Principles of Carpentry*, p. 206; Crawfurd's *East. Archip.* vol. i. 451.)

The teak of Malabar, produced on the high table-land of the south of India, is deemed the best of any. It is the closest in its fibre, and contains the largest quantity of oil, being at once the heaviest and the most durable. This species of teak is used for the keel, timbers, and such parts of a ship as are under water; owing to its great weight, it is less suitable for the upper works, and is not at all fit for spars. The teak of Java ranks next to that of Malabar, and is especially suitable for planking. The Rangoon or Burman teak, and that of Siam, is not so close-grained or durable as the others; it is, however, the most buoyant, and is therefore best fitted for masts and spars. Malabar teak is extensively used in the building yards of Bombay. Ships built wholly of it are almost indestructible by ordinary wear and tear; and instances are not rare of their having lasted from 80 to 100 years. Such ships are said

to sail indifferently; but this is probably owing as much to some defect in their construction as to the weight of the timber. In Calcutta ships the timbers and framework are always of native wood, and the planking and deck only of teak. The teak of Burmah, being conveyed with comparatively little difficulty to the ports of Rangoon and Martaban, is the cheapest and most abundant of any. It is largely exported to Calcutta and Madras.

A species of timber called African teak, the produce of the *Oldfieldia africana*, is pretty largely imported into England from the west coast of Africa. Though destitute of several of the most valuable properties of teak, it is, for some purposes, a useful timber. [OLDFIELDIA.]

Teany, Tawny, or Brusk. In Heraldry, a colour compounded of red and yellow, employed in blazonry, but rarely met with in English coats of arms, and reckoned one of the dishonourable colours. In engraving, it is represented by diagonal and horizontal lines crossing each other.

Tears (the English word *tear* is identical with the French word *larme*: tracing *tear* through the earlier forms *taer*, *tehr*, *tehar*, *tæher*, we reach the Gothic *tagr*, for which we have the corresponding Greek words **δάκρυ**, **δάκρυμα**, answering to the Latin *lacryma*, which is softened into the French *larme*: the Sanscrit form of the word is [*d*]*asru*, from the root *dak*, to bite—Max Müller, *Lectures on Language*, second series vi.). The fluid which lubricates the cornea of the eye, when secreted in excess, forms *tears*; they are limpid, saline, perfectly miscible with water, and have a slight alkaline reagency, owing to the presence of free soda. Their principal saline contents are common salt and a trace of phosphate of soda, and they contain traces of albumen; but the whole solid matter scarcely amounts to one per cent. When the lacrymal duct by which tears are conveyed into the nostrils is obliterated, and they flow over the angle of the eye, they become concentrated by evaporation, and leave an irritating muco-saline crust. The exact nature, however, of the animal matter contained in the tears has not been determined.

Teazel (A.-Sax. tæsl). The Fullers' Teazel, used in the dressing of cloth, is the flower-head of *Dipsacus Fullonum*, a biennial plant of the order *Dipsacaceæ*.

Tebeth. The tenth month of the Jewish ecclesiastical year, and fourth of the civil year. It corresponds to December.

Technology (Gr. τεχνολογία). A term invented to express a treatise on grammar.

Tecoma (Tecomaxochitl, its Mexican name). A considerable genus of *Bignoniaceæ*, composed of tall trees inhabiting the tropical parts of America, and valued chiefly on account of their hard almost indestructible timber, which has procured for several species the name of Roble-Oak. The White Wood of the West Indies (*T. leucoxylon*), the Guayacan of Panama (*T. Guayacan*), the Porrier de la Martinique of the Caribbean Islands (*T. pentaphylla*), and several Brazilian species, might be particularly pointed out as yielding first-rate timber for house and ship building, or wood for making bows for savages. Several species are of importance in medicine. *T. impetiginosa* abounds in tannin; its bark is bitter and mucilaginous, and it is used in the form of lotions, baths, &c. in inflammation of the joints and debility. *T. Ipe* has similar qualities, and is prescribed by the Brazilians as a gargle in ulcers of the mouth. The leaves of *T. subvernicosa*, known also as *Sparattosperma lithotriptica*, are bitter, acrid, and diuretic, and have a Brazilian reputation in calculus. When young, the *Tecomas* often have simple or unifoliolate leaves; but as they grow up, the leaflets increase in number, and become digitate. The large flowers are arranged in terminal bunches, and in many species appear after the leaves have fallen off.

Tectibranchiates (Lat. tego, *I cover*, and branchia, *gills*). A name given by Cuvier to an order of hermaphrodite Gasteropods, comprehending those species in which the gills are covered by a process of the mantle, containing a shell, or enveloped in a reflected margin of the foot. For this name that of *Monopleurobranchiata* has been substituted by M. de Blainville.

Tectizite. A mineral of uncertain composition, but supposed to be a hydrous sulphate of peroxide of iron.

Tectorium Opus (Lat.). In Ancient Architecture, the plasterer's work used upon ceilings and interior walls; it was a composition of lime and sand, and differed from stucco, which was called *albarium opus*. Great pains were taken to prevent work of this kind from cracking, by crossing layers of reeds, coated with argillaceous matter, upon it before it was coated with paint.

Tectrices (a word formed from Lat. tego, *I cover*). The name of the feathers which cover the quill-feathers and other parts of the wing. [COVERTS.]

Tee. [UMBRELLA.]

Teeth (Sansc. dat.; Lat. dens, dentis; Gothic tunthus; Ger. zahn, *a tooth*; the Greek, ὀδούς, ὀδόντος, being in all probability the same word). Teeth, properly so called, are parts peculiar to the vertebrate animals, composed of organic matter, hardened principally by the phosphate of lime. They are fixed to the bones of the mouth, and serve to catch, kill, hold, pierce, cut, or crush the objects of food, being variously shaped accordingly. Substances composed of softer material, generally horn, perform the analogous offices in the invertebrate animals, and are usually called *teeth*; horny material is substituted for teeth in a few fishes, in chelonians, birds, whales, and the *Ornithorhynchus paradoxus*.

In fishes the teeth may be situated on the premaxillary, maxillary, mandibular, palatine, vomerine, pterygoid, hyoid, or pharyngeal bones. In a few instances they are implanted in sockets or *alveoli*, or they may be fixed to an osseous base which is attached by ligamentous substance to the oral bones; but most commonly they are immediately anchylosed, or joined by

direct continuation of bony substance, to the bones themselves which encompass the mouth.

In reptiles the teeth may be found on the palatine, pterygoid, or vomerine, as well as on the maxillary and premaxillary bones. They are generally anchylosed, or confluent with the substance of the jaws; but in the plesiosauri and crocodiles they are implanted in sockets.

In mammals the teeth are confined to the maxillary and premaxillary bones, are always implanted in sockets, and in this class only may be so fixed by more than one fang or root.

Teeth generally consist of three distinct substances; viz. dentine, enamel, and bone or cæmentum, also called *crusta petrosa*.

The texture of the dentine is minutely tubular; that of the cæmentum, of combined tubules and cells; the earthy material is arranged principally in the interspaces of these cavities, which have definite arrangement and proportions in different vertebrate genera. The enamel, in mammals, consists of hexagonal filamentary columns.

In the human subject the teeth are called, according to their figure, *incisors*, *canines*, *bicuspids* and *molars*. The same terms have been transferred to the teeth of the mammalia generally, except that those which are homologous with the bicuspids in man are called *premolars* or spurious molars. A tooth is divided into a crown, a neck, and a fang or fangs. Other shapes are signified by the terms *tusk*, *sectorial*, *tubercular*, *scalprarial* or *chisel-tooth*, &c.

The vascular bodies concerned in their developement are called *pulp* and *capsule*; the dentine or body of the tooth is formed by the former, the enamel and cement are due to the latter organ.

In most cases when the pulp has developed as much dentine as forms the full-sized crown of the tooth, it diminishes in size; and as it continues to exercise its function during the progress of its diminution, a gradually decreasing fang is the result. When the diminution of the pulp, instead of being general, proceeds from two or three parts, a corresponding number of fangs are extended from the crown. But sometimes the pulp retains its full size and activity during the lifetime of the animal, in which case the part of the tooth lodged in the socket presents the same size and form as the protruded crown, of which it is a direct continuation. The fore teeth of the rat, beaver, and other rodents are familiar examples of these constantly growing teeth. But this is not the only mode in which excessive wear and tear of the teeth is provided for. In the elephant, when one grinder is worn down, it is pushed out and replaced by a second of subsequent formation. These successional teeth are formed in the elephant, each in a cavity at the back part of the jaw, behind the tooth which they are destined to succeed. In other animals, again, the teeth which suit the size of the jaws when young are pushed out by others which are proportioned to the size of the full-grown jaws. These, which are termed *permanent teeth*, succeed the *deciduous teeth* in the vertical direction, being developed in the substance of the jaws above the deciduous teeth in the upper and below the deciduous teeth in the lower jaw. Other molars are usually added behind. As the deciduous series of teeth are generally developed in mammals at the period when the young animal is suckling, they are commonly called *milk teeth*; but as in some rodents deciduous teeth are formed and shed before birth, they might be termed *uterine teeth*. Thus teeth may succeed each other in the horizontal or vertical direction. In the human subject all the deciduous teeth are succeeded vertically; but the additional teeth follow each other from behind forwards. In mammals, a tooth has not more than one successor in the vertical direction, but in reptiles and fishes there may be many such.

It is a singular but constant fact, that in mammals the permanent molar always presents a more simple crown than the deciduous one which it has replaced; thus, in man, the quadricuspid milk grinders are succeeded by the permanent bicuspides. For *dental notation*, see SYMBOLS, ZOOLOGICAL.

Teeth of Wheels. Teeth of wheels are generally the means by which the power of the first mover is conveyed to the working point of a machine; and it is obviously of great importance that they should be of such a form that as little as possible of the original power may be lost in transmission, and that the impulse should be conveyed through the train of wheels with a uniform force.

In the formation of the teeth of wheels, the object aimed at is to give them such a curvature that the angular velocities of the two pieces working together shall maintain the same constant ratio in all positions of contact. In order to preserve the constancy of the angular velocity ratio, it is only necessary that the acting faces of the teeth shall have such a form that the normal common to the two surfaces in contact shall always divide the *line of centres* (i.e. the line joining the centres of the wheel and pinion) in a fixed point. Now, the teeth of one wheel being assumed to have any form whatever, it is always *geometrically* possible to assign the form of those of another so that they shall fulfil this condition, and, consequently, work together correctly; but the forms which are found to answer in practice are limited to a comparatively small number. In a straight rack the curve both of the root and point of the teeth should be cycloidal, in a wheel the root should be hypocycloidal and the point epicycloidal, and in an internal segment the root should be epicycloidal and the point hypocycloidal. In the workshop, the curves of the teeth are struck out by rolling the template of the generating circle on a template of the pitch line, when a scriber or pencil marks the curve. More usually, however, the teeth are struck out by compasses, the roots being radii of the wheel, and the points segments of circles

struck from the centre of the adjacent tooth on the pitch line. The best diameter of the rolling circle for any pitch is 2·22 times the pitch, and no wheel intended to work smoothly should have less than fourteen teeth. The pitch should be as fine as is consistent with the required strength. When the velocity of the motion exceeds $3\frac{1}{2}$ feet per second, the larger of the two wheels should be fitted with wooden teeth, the thickness of which should be a little greater than that of the iron teeth. The breadth of the teeth in the direction of the axis varies very much in practice; but where the velocity does not exceed 5 feet per second, a breadth equal to four times the thickness of the tooth will suffice, or five times the thickness if the velocity is greater, the surfaces being kept well greased. But if the teeth be constantly wet, the breadth should be six times the thickness. The best length of the teeth is $\frac{5}{8}$ of the pitch, and it should not exceed $\frac{3}{4}$ of the pitch. In the Soho practice the length of the teeth is made $\frac{4}{12}$ of the pitch outside and $\frac{5}{12}$ of the pitch inside of the pitch circle: in the London practice $\frac{3}{12}$ of the pitch are outside and $\frac{4}{12}$ inside of the pitch circle. About $\frac{1}{8}$ of the pitch should be left unoccupied at the bottom of the pitch for clearance.

If t = the thickness of tooth in inches, w the weight upon it in pounds, and c a constant multiplier, which for cast iron is ·025, for brass 0·35, and for hard wood ·038, then $t = c\sqrt{w}$. This formula put into words is as follows:—

To find the proper thickness of tooth of a cast-iron wheel to transmit with safety any given pressure.

Rule.—Multiply the square root of the pressure in pounds acting at the pitch line by the constant number ·025. The product is the proper thickness of the tooth in inches.

Example.—What is the proper thickness of the teeth of a cast-iron wheel moved by a pressure of 233·33 lbs. at the pitch circle?

Here $\sqrt{233 \cdot 33} = 15 \cdot 27$, and this multiplied by $\cdot 025 = \cdot 381$, which is the proper thickness of the teeth in inches.

Tegmenta (Lat. from tego, *I cover*). In Botany, the scales covering the leaf-buds of the deciduous trees of cold climates.

Tegument or **Tegmen** (Lat.). In Anatomy, the general covering of the body. In Entomology, the term is applied to the coverings of the wings of the order *Orthoptera*, or straight-winged insects.

Teil-tree (Lat. tilia). The Lime-tree, *Tilia europæa.*

Teinds (from *ten*). In Scottish Law, tithes. By the course of various usurpations, the whole teinds of Scotland had become vested after the Reformation in the crown; or in private individuals, termed *titulars*, to whom they had been granted by the crown, or to the *feuars* or renters from the church. By a succession of decrees and enactments these tithes were generally rendered redeemable at a fixed valuation; and the clergy are provided for by stipends, paid by the commissioners of tithes (when these are vested in the crown) or by the titular. The minister can seek the increase of these stipends by process of augmentation and modification; and, if augmented, every heritor becomes liable in proportion to the amount of his teinds.

Teinoscope (Gr. τείνω, *I stretch*; σκοπέω, *I look*). The name given by Sir David Brewster to an instrument otherwise called the *prism telescope*, formed by so combining prisms that the chromatic aberration of the light is corrected, and the linear dimensions of objects seen through them increased or diminished.

'If we take a prism, and hold its refracting edge downwards and horizontal, so as to see through it one of the panes of glass in a window, there will be found a position, viz. that in which the rays enter the prism and emerge from it at equal angles, when the square pane of glass is of the natural size. If we turn the refracting edge towards the window, the pane will be extended or magnified in its length or vertical direction, while its breadth remains the same. If we now take the prism, and hold its refracting edge vertically, we shall find, by the same process, that the pane of glass is extended or magnified in breadth. If two such prisms, therefore, are combined in these positions, so as to magnify the same both in length and breadth, we have a telescope composed of two prisms; but unfortunately the objects are all highly fringed by the prismatic colours. We may correct these colours in three ways: 1st, We may make the prisms of a kind of glass which obstructs all the rays but those of one homogeneous colour; or we may use a piece of the same glass to absorb the other rays when two common glass prisms are used. 2nd, We may use achromatic prisms in place of common prisms. Or, 3rd, what is best of all for common purposes, we may place other two prisms exactly similar in reverse positions.' (Brewster's 'Optics,' *Cabinet Cyc.* p. 363.)

Professor Amici, of Modena, has recently constructed a combination of prisms of the same glass, in which the chromatic aberration is corrected, and a power of about three times obtained. The plan is well suited for opera-glasses. Amici's teinoscope consists of four rectangular prisms, having their refractive angles different, and connected by pairs; the two pairs being similar, those next the eye or the first pair are vertical, and the second pair horizontal, so that equal refraction is produced in every direction. The distance between each pair is about an inch and a half. (*Library of Useful Knowledge,* 'Optical Instruments,' p. 55.) Sir D. Brewster (*Optics*, p. 364) states that this instrument had been made by Dr. Blair as well as by himself, before it was proposed or executed by Amici.

Tej-Bul. A North Indian name for the warm spicy capsules and seeds of *Xanthoxylon hastile.*

Tekoretine. A crystallised mineral resin found in fossil wood in Denmark.

Telamones (Gr. τελαμῶνες). In Archi-

tecture, colossal figures of men used for the purpose of supporting entablatures. [CARYATIDES.]

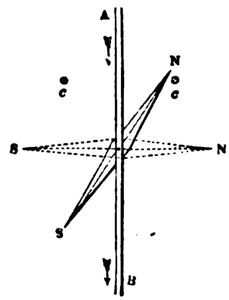
Telegram. A message transmitted by telegraph.

Telegraph (Gr. τῆλε, *afar off*, and γράφω, *I write*). The name given to a mechanical contrivance for the rapid communication of intelligence by signals. The term *semaphore* (Gr. σῆμα, *a sign*; φέρω, *I bear*) has been introduced by the French, and frequently adopted by English writers; but since the universal employment of the *electric telegraph* it has fallen into disuse. [SIGNALS, NAVAL.]

Telegraph, Electric. The electric telegraph, or, as it ought more properly to be called, the ELECTRO-MAGNETIC TELEGRAPH, has now superseded all other means of telegraphic communication. We purpose, therefore, briefly to describe the *principle* upon which these instruments are constructed, referring for minute details to the various works which have been published, and to the specifications of the many patents which have been issued upon the subject. The mutual relation of electric and magnetic currents will be evident from what has been stated elsewhere under the heads ELECTRO-MAGNETISM and GALVANOMETER, so that it will only be necessary to recapitulate such circumstances as have especial relation to telegraphic purposes.

When a current of voltaic electricity is traversing a metallic wire, a magnetic current is at the same time established, at right angles to, and as it were revolving about, the electric current as its axis; and if the pole of a magnet be supposed capable of freely moving in any direction, the tendency of such pole would be to revolve about the wire in question, or, rather, about the electric current which that wire carries. If a common magnetic needle, turning horizontally upon a point or pivot, be brought near the voltaic current, or to the wire conveying that current, the magnet will accordingly be deflected from its meridian. Supposing, for instance, the magnetic needle in its natural position, and pointing therefore north and south, to be approached by a wire transmitting the volta-electric current, held above, and parallel to the needle, the deflection of the needle will take place either to the right or left, or to the north or south, the direction of the deflection depending upon that of the electric current; and accordingly the tendency of the magnetic needle will be to place itself at *right angles* to the wire conveying the electric current. It is obvious, therefore, that the electric and magnetic forces may so far be said *to deflect each other*, and upon this principle the various forms of the galvanometer are constructed. Now, in reference to the application of such principle to telegraphic purposes, another form of apparatus must be adopted, in which the magnetic needle and deflecting current, instead of being placed horizontally, as in the galvanometer, are placed *vertically*, or perpendicularly, as in the annexed diagram, where A B represents a wire having a magnetised steel needle placed immediately behind it, and so adjusted as to hang vertically when at rest. If an electric current be now made to descend from A to B through

Fig. 1.



such wire, the needle will be deflected into the position N S; i.e. its north pole will turn to the right as the spectator stands before it; and on increasing the force of the electric current, the deflection of the needle might be so far increased as to cause it to place itself at *right angles* to the electric current, as shown by the dotted figure; but this may be prevented by the small studs *c c*, by which such extreme deflection is limited. If we now suppose the wire to be continued on, and bent up on the other side of the needle into the shape of the letter U, the current still passing onwards, i.e. down the limb A B and up B C (as indicated by the darts), then the portion of the current B C would also act upon the needle, and proportionately increase the deflection. If we now change the direction of the electric current, so as to send it down C and up A, then also will the direction of the deviation of the magnetic needle be changed, and its north pole, instead of pointing to the right, will point to the left. And if, by repeated convolutions of the wire, the electric current be made to pass many times around the magnetic needle, the deflection would be still further increased, so that, by the adoption of this latter expedient, or by the use of a *coil* instead of a single wire, the effect of the electric current may be so *multiplied* as to produce a considerable deflection by a comparatively feeble current. This is, in fact, the principle of the *galvanometric multiplier*, and is the form of apparatus used in the electric telegraph, as now most commonly constructed. The construction of this *coil* is shown in the annexed wood-cut. It consists of a polished

Fig. 2.

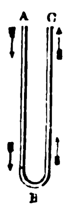


Fig. 3.

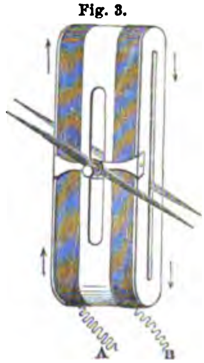

wooden or ivory frame, round which are bound some hundred feet of fine copper wire, covered with silk, which, being a non-conductor, prevents the lateral passage or transfer of electricity from wire to wire, so that the current, entering at A, passes through the whole length of the coil, and goes out at B. Two magnetic needles are fixed upon an axis which passes through the frame, one within, the other without the coil. The poles of these needles are in opposition to each other, and they are thus rendered *astatic*, i.e. they are not affected by the magnetism of the earth. This coil is so placed at the back of the dial plate of the telegraph, shown in the next diagrams, as to allow the outer needle to traverse right and left upon

Fig. 4.

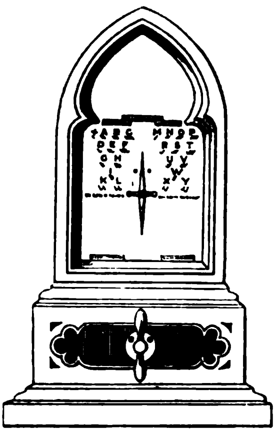

Fig. 5.

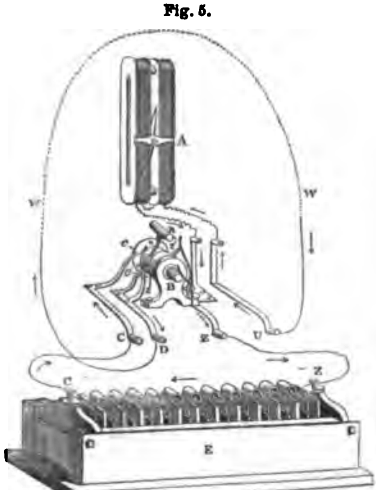


the dial plate. A more delicate instrument than the one now described is known as THOMSON'S GALVANOMETER. [TELEGRAPH, SUBMARINE.]

Having thus stated the *principle* upon which the usual form of the electro-magnetic telegraph is constructed, we may now further explain the details of its simplest form, in which *one* indicating needle only is employed, and which therefore is usually called the *single-needle instrument*. A front and back view of this telegraph is given in the preceding cuts, the battery being represented annexed to the lower, and the circuit through the galvanometric coil A being completed by the wire W W. The following description of the *working* of the instrument is abridged from Mr. C. V. Walker's *Electric Telegraph Manipulation*, to which we may here refer the reader for a variety of details respecting its construction and uses, which would have been irrelevant in this article.

The instrument has a twofold character: it is either *passive*, or ready for *receiving* signals *from* another instrument; or it is *active*, or ready for *transmitting* signals *to* another instrument. By describing first how it is fitted for *receiving* signals, and then how it is arranged for *transmitting* them, we shall be better able to analyse it, and comprehend its structure. The frame of the coil A (fig. 5) is screwed upon the face of the instrument, which face is a brass plate varnished on the inner side. Looking at the coil, a short wire from its *right-hand end* comes to a screw terminal, which, by a slip of brass, is connected with another terminal U. The *left-hand end* of the coil comes also to a terminal, from which a slip of brass descends to a brass plate, here partly hidden; but its form may be seen from a similar plate, visible on the left side. These twin plates are in metallic connection by means of the two upright *springs*, shown in the cut. The *springs* are of steel, and press strongly on two points in a short insulated brass rod *n*, which is screwed into the framework of the instrument. The left-hand plate is connected with the terminal D, also by a slip of brass. If, now, the two terminals U and D are connected by a wire W W, the circuit will be complete, as follows: from the terminal U into the coil at the right-hand side; out of the coil, at the left side, downwards to the right-hand plate; up the right-hand steel spring, across the brass rod *n*, to the left-hand steel spring: downward, by this spring, to the left-hand plate, thence by the slip of brass to the terminal D, and thence by the wire W W to the terminal U, whence we started. If, now, the wire from U went up the line of railway, and the wire from D down the line, and the circuit were in some way kept complete on the large scale, as it has been here described on the small scale, any electric current passing along the wire from a distant station would traverse this coil in its course, and would *deflect the needle*, and so make a signal.

So far for receiving a signal; now for sending one. Were we to go out on the open railway, taking with us a battery, and to cut any one of the wires, and place its two ends, thus obtained,

upon the two terminal ends of the battery, a current would pass along the line, and the needles on that line would be deflected; and if we changed hands, so as to reverse the connections, and consequently to reverse also the direction of the electric current, the deflections of the needles would be reversed. The same would happen were we to cut a wire inside the office, or inside the telegraph, and to treat it in a similar way. Now, in every apparatus contrived for transmitting signals, we have a *place corresponding to such a cut wire*; and near this place are the poles of the battery, mounted and movable, so that they may be readily applied in the breach, one way or the other as required. The place here (fig. 5) is the *top of the springs*. They are not *joined* to the brass rod *n*, but *press hard* upon it, and can readily be raised; and when either of them is raised, the circuit is broken. Now, near this place is a contrivance by which the poles of the battery may make a breach in the circuit, and be applied in the breach in either direction. The drum B is of box-wood, the ends *c* and *z* being capped with brass, and insulated from each other by the wood left between them. The drum is movable by a handle in front of the instrument, visible in fig. 4. A stout steel wire, c', is screwed beneath into the *c* end of the drum; and a similar wire z' is screwed above into the *z* end. These two wires are the poles of the battery, z' being connected with the zinc end, and c' with the copper, thus: from the copper end of the battery a wire is led to the terminal C; thence a slip of brass leads to a curved brass spring which presses on the drum at *c*; from the zinc end of the battery a wire goes to the terminal Z, and thence a slip of brass leads to a similar curved spring, pressing on the continuation of the *z* end of the drum, as shown in the figure. Whenever, therefore, the drum is moved, the steel wire z' will lift up one or other of the upright steel springs; it is now lifting up the right-hand one, and so breaks the circuit; but, by a little further motion of the drum, the wire c' will press upon the boss below, as shown in the figure, and thus there will be a battery-pole on each side of the breach, and a signal will be made on this, and on all instruments connected with it. From the peculiar arrangement of the drum, the motion can be changed as rapidly as the hand can move. The battery connections are shown exactly as they occur in practice; and the connections are such that if the right-hand spring is moved off, the needle moves to the right, and if the left, to the left. The needle on the face of the instrument always has its north end upward, and the needle within the coil its north end downward, so that, by the law elsewhere stated, if we look at the face of an instrument, and see the top end of the needle move to the right, we may be sure that in the half of the coil nearest to us the current is *ascending*.

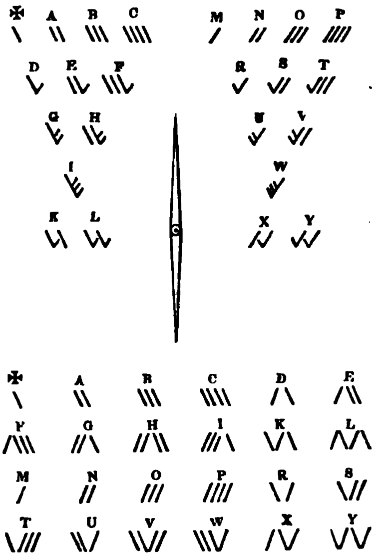
Now, as regards the *front* of the instrument, upon which the alphabet is engraved right and left of the needle, it will be obvious, from what has been said above, that the manipulator has it in his power to cause the dial-needle to vibrate or deflect to the right or left as he directs the electric current one way or the other through the coil, and this direction of the electric current is commanded in the way above described, by turning the handle at the lower part of the instrument to the right or left. When this handle is *vertical*, the current is altogether cut off.

The letters of the alphabet, and a few other signals, are indicated by the number of *beats* made by the needle, some of these beats being to the left and some to the right, the general rule being, that in the letters placed to the *left* of the needle the *last* beat to make any given letter is a *left-hand* beat, whatever other beats may enter into the production of the letter; thus, L requires four beats, and they are right, left, right, *left*, finishing with the *left*; so, again, the letters placed on the *right* of the needle finish with a *right-hand* beat, as, for instance, W, which is composed of four beats, three to the *left*, and the *fourth* to the *right*. The system upon which this single-instrument alphabet is formed is sufficiently simple. The symbol of each letter is placed underneath it, and consists of one or more diagonal lines sloping either to right or left, some of which are full length, and others half length; the direction of the diagonal is the direction of the deflection or beat, a deflection being made for each diagonal, the deflection corresponding to the *half length* being made *first*. D, for instance, is thus represented \/, and is made by a beat to the right, followed by a beat to the left; R is represented by ✓, and is made by a beat to the left, followed by a beat to the right; H is \\✓, two to the right and two to the left; W is ✓, three beats to the left and one to the right, and so on. The scheme of the code is: one, two, three, and four left-hand beats for the first four signals; then one right-hand, and one, two, and three left-hand beats for the next in order; then two right-hand and one and two left for the next; then three right-hand and one left; then a left, a right, and a left; and lastly, right and left, right and left, \/\/, which reaches L, and comprises the first half of the series. The other half are the counterparts, with the beats reversed. To render this description more intelligible, we give a separate representation of the dial alphabet, in which the direction and number of beats for each letter are shown separately.

In the following diagrams, the symbol like the Maltese cross ✠, indicated by one beat to the *left*, and which is termed *stop*, is used by the *sender* of a message, *at the end of every word*, and by the *reader* or receiver of the message, when he does *not understand* the previous word. On the other hand, a single beat to the *right* (indicating the letter M upon this form of the instrument) implies that he *does understand*. When, in this or other form of the needle tele-

graph, *numbers* are to be transmitted, which, however, is very rarely necessary in the form of *numerals*, conventional letters and signals are settled upon for the purpose.

Fig. 6.



Our object here is, merely to render the principle of this form of the electric telegraph intelligible, and therefore we have selected the simplest instrument; but at all the principal stations a DOUBLE-NEEDLE INSTRUMENT is employed, which may, in fact, be regarded as two single instruments capable of being worked separately or together. With this double telegraph the reading of the signals is much more rapid, but it has the inconvenience of requiring a separate line-wire for each needle; the signals also are different from those of the single instrument, but the *principle* is in both the same.

It is obvious, from the laws which govern the transmission of what we call the *electric current*, that when, by its means, a message is to be sent to any distant station, as, for instance, from London to Dover, there must be a means by which the current may return from Dover to London, and this was formerly effected by a separate wire; so that each single telegraph required two wires, one down the line to Dover, and one up the line to London, and a double-needle instrument could only be worked by four wires, by which much expense, and occasionally inconvenience, was incurred. But, about the year 1837 it was discovered that the circuit might be completed, or at least that the return-wire might be superseded, by what has been called the *earth circuit*, so that, instead of using *two* lengths of wire, one only is employed for each needle, and the terminal or return wire of the Dover instrument is connected with the earth at Dover, while the other terminal of the London instrument is similarly connected with the earth at London, and, strange to say, it is found that this transit by the earth is more perfect, *i.e.* presents less resistance to the passage of the electricity than if a return-wire had been used. This statement will, perhaps, be rendered more intelligible by the annexed cut, in which the

Fig. 7.

insulated line-wires proceeding from London at L to Dover at D are shown following the line of railway, whilst the dotted line between the buried copper plates R R (or gas or water pipes at each extreme) shows the supposed direction of the electric current in completing the circuit. Every telegraph station is thus provided with an *earth-plate.* Although the conducting power of the earth between R and R is many thousand times less than that of copper for equal sectional areas of conductor, yet the sectional area of the earth exceeds so enormously that of the copper or iron wires employed in telegraphy, that the return current is thus conveyed with far less resistance than would be the case if a separate wire were provided for its transit; indeed, some have discarded altogether the notion of *conduction* in these cases, and have regarded the earth as a reservoir in which positive and negative electricity are equally and indifferently lost, absorbed, or neutralised; the positive end of the battery freely giving off positive electricity to the earth at London, and the negative end giving off negative electricity to the earth at Dover, or vice versâ, as the case may be.

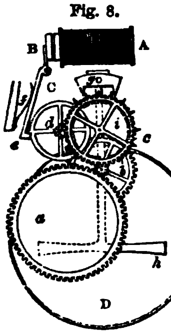
We have now endeavoured to render intelligible the principle upon which signals are communicable between distant stations by electro-magnetic means, and have only to notice a few of the appendages, as they may be termed, to the talking part of the apparatus.

One of them, and an important one, is the *alarum*, or *bell signal*, by which *audible* notice is given from station to station of their desire to talk to each other through the telegraph. These bell signals may be either altogether independent of the telegraph, and rung by a separate wire, or they may be rung by the same wire which actuates the telegraph, and which in that case is so arranged that the electric current may be diverted through the bell magnet, or through the telegraph, as occasion may require; and in this case, if we suppose the bell to be in the circuit, its *ringing* announces the wish of the distant station, say of Dover, to communicate with London; then London, on hearing the bell, turns on the current to the bell at Dover, to announce that the signal has been successful; the current is then turned off the bells on to the

needle-coils, and the message transmitted in the usual way. When separate and independent wires and bells are employed, they are always in the circuit, and may be rung whenever required. For particular purposes the bells may serve as special signals; and when rung once, twice, thrice, and so on, may thus serve to announce something that has happened at the distant station.

These *alarums* are rung by means of an *electro-magnet*, i.e. a short rod or core of *soft iron*, wound round with a sufficient length of silk-covered copper wire; this core becoming a powerful magnet whilst an electric current is traversing its copper coil, and returning again to its indifferent or normal state the moment that the electricity ceases to circulate. A side view of an *alarum* is given in the annexed diagram. A is the electro-magnet; in front of it is a soft iron keeper B. This keeper is attracted by the poles of the electro-magnet *every time* a current is made to circulate around it, and *as long* as it is in circulation; and attraction ceases the moment the current ceases. To prevent the keeper remaining attracted, which sometimes happens, even after the force ceases to circulate, it is prevented from actually touching the pole of the magnet by two ivory studs, or sometimes merely by the intervention of a piece of paper; but it is so adjusted that, when in its state of rest, it shall be as near as convenient to the poles of the magnet. The

Fig. 8.

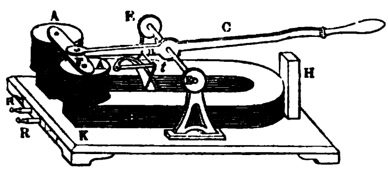


rest of the figure represents the mechanism by which the bell is rung. The keeper B is mounted on the shorter arm of a lever C; the other end of the lever terminates in a catch *e*, which catches a pin in the circumference of the wheel *d*, and prevents it moving; *f* is a slender spring pressing against the long arm of the lever C, by means of which the keeper is restored to its normal position when attraction ceases, and the catch *e* is made to act; *a* is a box containing the mainspring; *b*, a toothed wheel connected with *a* by a pinion; *c*, a toothed wheel having a pinion working in *b*; *d*, the wheel that carries the stop, and connected by its pinion with *c*; *g* is an escapement, working in pallets on the wheel *i*, which is on the same axis with the wheel *c*; *h* is the bell hammer: it is virtually a short pendulum, its connections and action being quite similar. When the voltaic current is made to pass along the wire of the coils A, the soft iron core is magnetised, and the keeper B is attracted; this raises the catch *e*, and so allows the wheel *d* to move. The machinery being thus liberated, the mainspring in the box *a*, which is kept wound up, sets it in motion, and the pendulum hammer *h* vibrates rapidly and strikes the bell D, which is shown also in section. When the magnetisation ceases, with the cessation of the current, the catch *e* is pressed into its place again by the reacting spring *f*, and the ringing terminates.

It will be seen, from this description, that the alarum is sounded by ordinary mechanism, and that the office of the voltaic force is merely to move a lever and liberate the machinery; whence it is obvious that there is little limit to the amount of noise which may be produced.

In some other forms of telegraph, the bell, instead of being sounded by the detachment of a common ringing scapement, is rung by the direct blows of a hammer attached to the keeper of the magnet itself; and there are several modifications of this contrivance, by which a single blow or a continuous ringing may be effected. For ringing bells at short distances, and in cases where a voltaic battery would be inconvenient, a current of magneto-electricity is substituted, which is most simply obtained by the following form of apparatus: A A are coils (similar to the coils above described); the two bars of iron which pass through the coils are connected by their upper ends to a strip of iron F, the lower ends resting on the magnet B; thus they form what is commonly termed a keeper, by connecting the two poles of the magnet; F is joined to a lever C, which

Fig. 9.



is attached to a shaft that works in bearings E E; the spring seen under lever C is for forming a short circuit; *n*, a small ivory pin for insulating the wire *t*; R R, two terminals, where the wires coming from the coils terminate; H, a block for stopping the entire descent of lever; K is the stand, to which the whole apparatus is firmly fixed. As long as the iron bar remains on the magnet, no effect is produced; but sharply depressing the lever whereby the iron bars are detached from the magnet, a current of electricity is produced, passing through the coils and along the line to the bell.

Such is an outline of the principle and construction of the electric telegraph ordinarily employed in this country; but the instruments,

and even the mode of producing the electric current, are susceptible of endless modification; thus, in the so-called *magnetic telegraph*, permanent magnets are made to evoke the necessary current. Conspicuous alike in the early history and in the latest developements of this magnificent invention, Professor Wheatstone has recently constructed instruments of the most ingenious construction, which are not only capable of working with electric currents, produced by a mere pocket magnet through sixty miles of wire, but which also print off the messages upon a strip of tinfoil in plain Roman characters. These instruments are especially adapted and now extensively used for private telegraphy. The printing telegraph deposits its messages unseen in a locked box, where they await the arrival of the owner should he not be present to receive them, thus dispensing with the employment and constant attendance of a receiving clerk. In another telegraph, patented by Professor Wheatstone, a hand points to the letter itself on a dial, the message being read off by pressing a stud near the letter. A company has been established to erect and maintain wires in London and the principal provincial towns for private use. Thus, a merchant at his suburban residence can have constant communication with his offices in town by instruments which are always ready for use, and which require no batteries or chemicals, the only power used being that necessary to rotate a small magnet, an amount of mechanical force easily applied even by a child.

In the bell telegraph of Sir Chas. Bright, the signals of the Magnetic Company's needle instrument are given by strokes upon two bells of different pitch, one of which represents the movements of the needle to the left, the other the movements to the right. We have also the printing telegraphs of Morse and Bain, which record the signals received in an alphabet composed of dots and strokes. Morse's system is generally employed throughout Europe.

There are also other kinds, all of which exhibit the most surprising ingenuity. The first is the printing telegraph of Mr. Hughes, a marvel of mechanical skill. The second is the pantelegraph of the Abbé Caselli, who, not content with the transmission of autographic communications, will send, with admirable precision, a portrait. This is accomplished by the aid of two pendulums, having a movement absolutely synchronous. One of the pendulums carries a pen or pencil of fine platinum wire (in connection with the line and the line battery) over the surface of the despatch or drawing, previously written or executed in insulating ink upon a metallic paper. The other, at the corresponding station, carries an iron pencil, likewise in connection with the line, over a paper prepared with a solution of the yellow cyanide of potassium. The electrical circuits are so disposed, that when the platinum point in its passage over the original writing or drawing touches the metallic surface of the paper, there is no emission of current along the line; while, on the other hand, when the point touches the insulating ink, an emission of current takes place, and the iron point passing at the other end of the line over the prepared paper leaves upon it a blue mark. This movement of the two pendulums being precisely equal, the reproduction of the drawing or despatch is absolutely exact.

The third is the type-printing telegraph of the Chevalier Gaetano Bonelli, the former director of telegraphs in Italy, and the inventor, among other beautiful applications of electricity, of the electric loom. It is to M. Bonelli that we are indebted for the bold idea of uniting the science of electricity with the art of Gutenberg, and of practically demonstrating that an ordinary typographic composition, fit for local use, may be unerringly reproduced at almost any distance. From this idea naturally arose the conception of converting the telegraph stations upon the main lines into so many type-setting workshops, of suppressing altogether every kind of delicate mechanism, of putting aside conventional alphabets, those pregnant sources of error—in a word, of reducing telegraphic science to a simple craft, within the reach of the most ordinary intelligence. Independence of synchronic movement or elaborate clockwork, freedom from all delicacy in the mechanical detail, and the substitution of the most absolute simplicity in the place of that which, until now, demanded a special knowledge to keep the machines in working order, are among the practical advantages obtained by Bonelli's system; while, on the other hand, a rapidity and certainty, never even hoped for, are insured. The principal features of this machine are two tables in cast iron, placed inversely to each other at the corresponding stations, and each provided with a miniature railway, over which run two waggons, one carrying the type-set message, the other the paper, chemically prepared with nitrate of manganese, and two combs, formed of the extremities of the wires of the line, one of which touches the type at one station, while the other passes over the prepared paper at the other—a spring-catch to each of the waggons setting them free to move by the closing of an electrical current. Neither on short circuit nor at a distance has the slightest difficulty been experienced in working the Bonelli machine—a well-considered system of counter-currents having completely annihilated the inconveniences which, from the time of Bain to the present moment, it had been impossible to avoid in electro-chemical telegraphy. Caselli was the first to conquer the difficulties which rendered the chemical process useless at a distance. Ten type-setters under Bonelli's system can compose at least 300 despatches per hour, and these may be transmitted in less than that time. As regards rapidity, Bonelli's telegraph has the advantage of three to one over the system universally adopted,

and has further this immense superiority, that all errors are avoided, and the necessity of repeating figures and proper names is entirely done away with. It has been asserted that an unattainable identity in the electrical condition of the five wires is absolutely indispensable to the well-working of the system. The wide differences of insulation in the line between Manchester and Liverpool has proved the contrary, actual practice having shown that a variation of from 40° to 50° in the amount of loss to earth does not make the slightest appreciable difference in the legibility of the printing.

When telegraphic lines are of great length, a serious obstacle to the transmission of signals arises. It is found that in long aërial or submarine lines, the speed at which distant signals can be sent is much diminished, the retardation increasing as the *square of the length of the line.* On a land line 2,000 miles long, consisting of iron wire one-fourth of an inch in diameter, the maximum rate at which a message can be sent is about 20 words a minute; hence on a line 1,000 miles long, a speed of 80 words per minute might be obtained; and on a line 500 miles, 320 words a minute would be distinctly transmitted. But as the maximum speed in telegraphing is about 50 words a minute, the retarding influence is only felt on extremely long unbroken lines, and more especially on those laid in the earth or sea, such, for example, as the Atlantic cable.

The cause of this retardation is what is termed *lateral induction.* When an electric discharge is sent into a Leyden jar, the electricity on the inner surface acts through the glass upon the neutral outer coating, charging it with the opposite electricity by influence or induction. If, now, an open glass cylinder of indefinite length be imagined coated within and without by tinfoil, and an electric discharge be sent at one end into the inner coating, the discharge will be propagated and expended in two directions—*onwards* in the interior by conduction, and *laterally* through the glass to the exterior by induction. Now, in this arrangement, the progress of the former involves the latter, and as time is required for induction to take place, the discharge will be greatly retarded in its progress by the influence of the outer conducting surface. Moreover, if a single discharge be sent into the coated cylinder, no free electricity will be apparent at the far end, until the entire outer coating has been inductively charged with the opposite electricity. When thus charged, if the two coatings be joined by a conductor, the opposite electricities combine, and the discharge takes place.

A similar effect takes place when an electric current from a voltaic battery is sent into such a Leyden arrangement, and just such a system is a telegraph cable. The conducting wire corresponds to the inner coating of the Leyden jar, the insulating material with which the wire is covered corresponds to the glass, and the earth or water surrounding the cable to the outer coating. Thus, a coil of submerged cable may be charged and discharged precisely like a Leyden jar. Owing, then, to the act of induction, a signal takes a certain time before it is apparent at the remote end of a cable; and before a second signal can be sent, a further time must elapse in order to discharge the line. It is mainly on this account that the speed of transmitting distinct signals through long lines is so limited. In a long aërial line, the air between the wire and the ground plays the part of the insulator, and the lateral induction is far less than in cables.

No way has yet been found of preventing this lateral induction; but its retarding influence has been diminished by the use of a *key,* or make-and-break, of peculiar construction. This key has a double action. By pressing it, the telegraphic line is first put in connection with one of the poles of the battery, and then immediately with the ground. The first contact charges the cable, the second allows it to be discharged. On the rapidity with which the cable can be charged and discharged, and successive pulses of electricity caused to follow each other without commingling, depends the *speaking power* of the cable. By the use of this double-acting key, the *operating power* of the Atlantic telegraph was said to be increased one-half; so that at present six to seven words can be transmitted through each of the Atlantic cables in one minute. [TELEGRAPH, SUBMARINE.]

Telegraph, Marine. An instrument used in ships and steam vessels to convey the orders of the captain, when standing in a high position near the middle of the ship, to the steersman and to the engineer. The forms of apparatus used for these purposes are very various. In some cases an electrical mechanism is used, which causes a hand at one end of a wire to follow the motions of another hand situated at the other end, and which is moved by the captain into the position necessary to point out on a circular dial the particular order which he wishes to have obeyed. Usually, however, the engineer's telegraph consists of a vertical spindle with a handle and dial on its upper end, and a corresponding dial with hand at its lower end, in the engine room. Thus when the captain moves the handle into the position answering to the particular order which he wishes to give, by the same operation he rings a bell so as to draw the engineer's attention to the altered position of the hand. To direct the steersman, three labels, one indicating *port,* another *starboard,* and another *steady,* are exhibited near where the captain stands, and at night these are exchanged for different coloured lights, and by the nature of the light or label exhibited the steersman is guided in moving the helm.

Telegraph, Submarine. A cable composed of a core of copper wires insulated by Indian-rubber, gutta percha, or other non-conducting material, and protected by tarred hemp, and generally by external iron wires.

This cable is laid along the bottom of the sea, and through the insulated wires telegraphic messages are transmitted. Submarine telegraphs have been in successful operation in narrow tracts of water for many years. But the successful establishment of two different lines across the Atlantic constitutes a new epoch in the art, and as these telegraphs may be expected to constitute the type of such lines of communication in the future, it will be sufficient here to describe the principles and material features of those undertakings.

'The problem,' to quote from an admirable article contributed to the *Popular Science Review* for October 1866, 'may be stated thus: Given the two poles of a galvanic battery at Valentia, it was required to provide a path from one to the other, which, though reaching to the other side of the Atlantic and back again, a distance of some 3,500 miles, should offer less resistance to the passage of an electric current than any other possible route by which it could traverse the few feet or inches by which the two poles were separated. For this purpose it was necessary, in the first place, to diminish as much as possible the resistance which would be encountered by a current passing from one pole of the battery to Newfoundland, and returning thence to the other pole; and, in the second place, to make as great as possible the resistance offered to the passage of the current from one pole to the other by any shorter path.

'The first of these objects was effected by extending between Valentia and Newfoundland a copper wire, pure copper having the smallest electrical resistance of any substance known, with the exception of silver. When the Irish end of this wire is connected with the positive pole of the battery, and the other end of the wire and the negative pole of the battery are at the same time each of them connected with a large metallic plate (called an *earth-plate*), either buried in the ground or sunk into the sea, the current starting from the positive pole passes along the wire to Newfoundland, then through the Newfoundland earth-plate into the ground or into the ocean, and so back through earth or water, or both, to the Valentia earth-plate and the negative pole of the battery. This conductor is formed of a strand of seven wires, each of them 0·048 inch in diameter, and therefore together equivalent to a single wire of nearly 0·144 inch diameter. Its length, as laid, is about 1,858 knots, and each knot has an electrical resistance at 24° C. or 75° Fahr. equal to 4,272 times the unit or standard of resistance adopted by the Committee of the British Association on Electrical Standards, and known as the *British Association unit*; consequently, the resistance of the whole length of the conductor may be taken in round numbers as equal to 7,500 B.A. units, allowing for a diminution of resistance caused by the low temperature of the bottom of the Atlantic. . . .

'Let us try to put this comparison between the resistance of the conductor and that of its insulating coating into a more exact form. We have already estimated the former at about 7,500 B.A. units; a statement by Mr. Latimer Clark, in the *Mechanics' Magazine* for the 10th of August, enables us to estimate the latter According to this statement, the resistance to the escape of electricity from each knot of the conductor through the gutta-percha covering into the ocean may be represented by 2,200,000,000 B.A. units; consequently the resistance to the escape of electricity from the whole 1,858 knots of the cable will be equal to $\frac{1}{1858}$ of 2,200,000,000, or 1,180,000 B.A. units; or, in other words, it is about 157 times more difficult for an electric current to find its way back to the battery by taking a short cut across the gutta percha into the water, than by traversing the whole distance from one end of the cable to the other and back by the way prepared for it.'

We now come to the engineering part of the undertaking,

The first attempt to lay a submarine cable across the Atlantic was made in 1857 by the Niagara and Agamemnon. That cable had a central core formed of seven copper wires of No. 22 wire gauge, laid six round one, and insulated by three layers of gutta percha. The insulated wires were protected by a serving of tarred hemp surrounded by eighteen strands of charcoal-iron wire, each strand being composed of seven wires of 22½ wire gauge. The weight of this cable per knot was in air 20 cwt. and in water 13·4 cwt., and its contract breaking strain was 4·85 times its weight per knot in water. The total length of cable shipped was 2,174 knots. After various failures in 1857 and 1858, the cable was at length laid and messages were transmitted through it. But the transmitting power soon ceased, from some unexplained cause. It was found, however, by subsequent experiment that the insulating power of gutta percha was much impaired by being subjected to a great pressure of water.

In 1864, a new cable was manufactured with seven copper wires of No. 18 wire gauge embedded in Chatterton's compound, and insulated by the application of four layers of gutta percha alternated with four layers of Chatterton's compound. Great care was taken in the selection of the copper, as it was found that different specimens varied in conducting power as much as 85 per cent., the presence of arsenic being especially prejudicial. It was stipulated that the conducting power of the copper employed in the construction of the Atlantic cable should not be less than 15 per cent. inferior to that of pure copper, and all the copper used was carefully tested to determine its conducting power. The diameter of the core or assemblage of insulated wires was ·464 inch, and its weight per knot was 400 lbs. The core was surrounded by a padding of soft jute yarn saturated with a preservative mixture; and around the covering of jute ten wires of Webster and Horsfall's homogeneous metal, ·095 inch diameter, each wound round by five strands of Manilla hemp saturated with the

preservative mixture, were spirally wound, forming the protective covering of the cable, which had a breaking strength of 7 tons 15 cwt. Its weight per knot in air was 35 cwt. 3 qrs. and in water 14 cwt. Of this cable 2,400 miles were shipped in the Great Eastern to connect Valentia and Newfoundland, 1,640 miles apart; and on June 24, 1865, the Great Eastern left her moorings in the Medway, and began to lay the cable on July 23. But after a considerable length of cable had been paid out it broke, and the attempts made to recover the broken end failed. Owing to the advanced period of the year, and the defects of the grappling apparatus, the vessel had to return.

Nothing daunted, however, by this want of success, the telegraph company proceeded to manufacture a new cable, of which the core is exactly the same as that of the cable of 1865. The protective covering consists of ten wires of ·095-inch diameter, drawn from Webster and Horsfall's homogeneous iron and galvanised, and each wire is wound round by five strands of white Manilla yarn. These wires are wound spirally round the core, which is padded with ordinary hemp soaked in a preservative mixture. The weight of this cable, known as the 1866 cable, is 14¾ cwt. per nautical mile in water and 31 cwt. in air, and its contract breaking strain is 12 times its weight per knot in water. The paying-out machinery consisted of six grooved or V wheels, the shafts of which were fitted with brakes, and the cable was pressed into the grooves by six riding wheels, the shafts of which were also fitted with brakes and were kept down by levers loaded with weights. These wheels served to keep the cable tight on the paying-out drum, which was 6 feet 1 inch diameter and 1 foot broad. The cable made four turns round this drum, and was prevented from over-riding by suitable directors. From the paying-out drum the cable passed over a dynamometer wheel, which deflected it by a lever loaded with weights, and thence it passed over a V wheel overhanging the stern, being sustained in that position by strong projecting girders. The cable issued through a bell-mouthed casting intended to prevent chafing against the flanges of the V wheel.

The Great Eastern, thus fitted, started on June 30, 1866, on her mission to lay the cable. Having succeeded perfectly in this task, she proceeded to pick up the end of the 1865 cable, in which also she succeeded, and, a splice being made, the residue of that cable was also laid, two lines of submarine communication being thus opened between Europe and America. The paying-out machinery for laying the 1866 cable was fitted with a pair of trunk engines, made by Messrs. John Penn and Son, capable of working up to eighty horse-power, for the purpose of hauling in the cable, if that operation should be found necessary to discover a flaw, or otherwise. Picking-up gear, connected with two similar engines, was fitted to the bow of the vessel, and this gear was made very much stronger than that employed in 1865. There can be no doubt that submarine telegraphs will now be carried through every sea; and the experience which has been acquired in the construction and laying of these telegraphs will divest such enterprises of the speculative and precarious character hitherto attaching to them. The instrument employed for receiving electric signals through the Atlantic telegraph lines is a reflecting galvanometer, of the exact form drawn and described under the article THOMSON'S GALVANOMETER.

Submarine telegraphs are examined and repaired, when necessary, by the aid of a steamer with proper gear for raising the cable to the surface, and paying it out again after the repair has been effected. A large sheave, from 2 to 3 feet diameter, and 8 to 12 inches broad, formed with deep flanges, is supported by cantilevers over the bow of the vessel, and cast-iron cheeks are fixed to the cantilevers to prevent any rope which passes over the pulley from slipping out if drawn sideways. A picking-up pulley or drum, 6 or 7 feet in diameter, and 12 to 15 inches broad, is set in the fore part of the ship, and this pulley is driven by an engine usually of about twenty horse-power, but more in the case of cables laid in deep seas. Three or four turns of the grapnel rope or cable are taken round this drum, which, being put into revolution by the engine, hauls the rope in, and a stationary piece of iron or steel is so placed as to press the turns of the cable endways on the drum during its revolution, so as to shift it over, or *fleet* it, as the technical phrase is. In some cases this drum overhangs; in other cases it is supported by a bearing at each end, but the former arrangement is the more convenient. A similar drum with a proper break is usually fitted at the stern for paying the cable out as it is repaired. Sometimes a cable is under-run by passing a pulley under it, set in a stirrup hanging over the bows; but this can be done only in shallow seas. For grappling a cable, short grapnels with four prongs, weighing from 30 to 60 lbs., are commonly used—two of the prongs necessarily engage the ground—and a piece of ¾-inch chain, 20 or 30 fathoms long, is attached to the grapnel, to which in turn is fixed a 6 or 8 inch drag rope. In shallow water, the length of drag rope is made three or four times the depth, but the Atlantic cable was hooked with a length of only one-fifth more than the depth.

It would be impossible within the limits of this article to notice the various methods of constructing submarine telegraphs which have been propounded by different inventors. It may be stated, however, that Mr. Siemens has made some good telegraphs by insulating the wires by ribands of Indian-rubber. One of these is laid above and the other below the wire; and the edges being cut off by circular shears, the cut edges when pressed together by rollers cohere. Similar ribands are then applied over the first, but breaking joint with them. A tape saturated

with a substance impervious to water is then laid on spirally. Three insulated wires and three strands of hemp are then made into a cable, over which is laid a sheathing of hemp, and finally a serving of galvanised wires. Mr. Hooper also insulates his wires with Indian-rubber, which he vulcanises by exposing it for some hours to a heat of 280° Fahr. after it has been applied to the wires. It is alleged that greater durability is thus obtained, and it has been proved that the insulating power of such a coating is at least forty times as great as that of gutta percha.

Telemachus. [Phaethon.]

Teleology (Gr. τέλος, *an end*, and λόγος). The doctrine of final causes is so called. The *teleological argument* for the existence of a Deity is derived from those marks of design apparent in the universe, which not only imply an intelligent Creator, but demonstrate at the same time His moral attributes. When these are derived from material nature, the argument is styled *physico-theological*. The reader will find in Whewell's *Bridgewater Treatise* an explanation of Bacon's meaning in banishing the doctrine of final causes from the domain of physical science.

Teleosaur (Gr. τέλειος, *perfect*; σαῦρος, *a lizard*). The name of a genus of fossil Saurian reptiles, resembling the *Gavials*, but having the vertebræ united by flat surfaces, instead of ball-and-socket joints. Fossil Crocodilia exhibiting this character ranged from the lias to the chalk inclusive.

Telephassa (Gr. Τηλέφασσα). In Greek Mythology, the wife of Agenor, and mother of Cadmus, Europa, and Phœnix. In some versions of the myth she is the wife of Phœnix, while the wife of Agenor is Antiope. In the common legend, when Europa was carried away by the white bull, Telephassa with Cadmus sought her lost child over land and sea, until at length she sank down in the weariness of death on the Thessalian plain. She is thus a being who moves from east to west, seeking for something which has gone before her, but never attaining to it. This simple tale is chiefly valuable as containing names which explain themselves. Her home is in Phœnicia, the purple land, in which dwells Phœnix, the same mythical being who in the *Iliad* is the teacher of Achilleus, and who for the benefit of the hero recites to him the story of Meleagros and Atalantê. Her name, signifying literally *that which shines from afar*, describes the shooting rays of light which dart across the heaven in early morning. Thus Telephos answers to Telephassa, the same idea being expressed in the name Telemachus. [Odysseus.] The word Europa, like many other mythical names, describes the broad flush of light which overspreads the sky before the rising of the sun; to this class belong such names as Euryphassa, Euryanassa, Euryganeia, Eurydikê, Eurymedusa, Eurytos, Eurynomê. A still larger class of names expresses the simple notion of light or splendour, as Phaethon, Augê, the mother of Telephos; Phaëthusa and Lampetiê, the children of Neæra, the early morning, who tend the cattle of Helios in Thrinakia; Autolycus, the grandfather of Odysseus; and Pasiphaë, the wife of Minos. In many cases a confusion has arisen between words denoting light and the names of beasts, which, however, belong not improbably to the same root. Thus, the myths of Arcas and Arcturus [Rishis], which denoted originally the bright and glistering stars, have been modified, like those of Lycaôn, by tales of transformation into bears and wolves—a point which should perhaps be taken into account in attempts to trace to its source the superstitions concerning Lycanthropy. The name Lykios, as applied to Phœbus, the light-giving god, retained its signification of brightness; but the way in which Æschylus plays on the two meanings of λευκός, *brilliant*, and λύκος, *a wolf* (*Sept. c. Theb.* 145), illustrates the method in which these tales of metamorphosis grew up. Names expressing only brightness became, in the same way, geographical designations of countries; but Lykia, or Lycia, like Phœnicia, Delos, and Ortygia, were all names of the Eastern or Morningland, which lay to the east of those who applied these names, as the Hesperian lands lay always to the west. The list of self-interpreting names may be extended indefinitely; and when these names occur in legends which are manifestly solar, as in that of Endymion and Selênê, or in the stories of beings who belong to the large class of solar heroes, as Perseus, Theseus, Œdipus, &c., they tend at each step to strengthen the position that mythology had its origin in phrases descriptive of sensible phenomena. Thus, Telephos is the son of Augê or *light*; Theseus, of Æthra, *the air*; Œdipus, of Iocastê, who, like Iolê, Iobates, Iamos, &c., embodies the violet hue of the morning sky; Phrixus and Hellê, of Nephelê, *the mist*, in the tale of the Golden Fleece. Other names, again, denote the light which springs up in the east as the sun sinks down in the west, whether by the reflected flush of solar light, or by the rising of the moon; thus, Antigone, the being who rises opposite (ἀντί), cheers Œdipus in his last hour: and the same idea is expressed not less clearly in the name Antiope. The names here mentioned explain themselves: others, as Erinys, Procris, Sarpêdon, Kephalos, Hermes, Achilleus, Ixion [Tantalus], become clear on a comparison with Sanscrit names, and with passages in the Veda which throw light on the origin of legends as complicated as those of the Trojan war.

Telephos (Gr.). In the mythical genealogy of the Arcadians, a son of Heracles and Augê (*the light*). His name, like that of his mother, belongs to that class of names in mythology which explain themselves [Telephassa]; and the incidents of the tale, in their many conflicting versions, likewise illustrate the solar character of the legend. Like Paris and Œdipus, he is exposed on a hill side, and, like them, he is guarded or suckled by a wild beast. Like Œdipus, he consults the Delphic oracle to know where he may find his parent, and, in harmony

with the old mythical speech, he is bidden to seek for Augê in the eastern land of Mysia. There, accordingly, he finds her, and becomes the husband of Argiope, another name denoting simply brightness.

Other versions related that Teuthras, king of Mysia, sought the aid of Telephos, promising to give him his daughter Augê in marriage; and thus the story of Œdipus and Iocastê is imported into the myth, with this difference, that Augê refuses to agree to the marriage and threatens to murder her future husband, who, by the intervention of Heracles, learns that Augê is his own mother. This is manifestly only a device to reconcile the story with the ethical sentiment of a later age.

During the reign of Telephos, Agamemnon led the Achæans against Troy. When they entered Mysia, they were repelled by Telephos, whom Dionysus caused to stumble over a vine; Achilleus was thus enabled to inflict on Telephos a wound which, like those inflicted by the arrows of Heracles, could not be healed: incurable wounds being hence called τηλέφεια τραύματα. But again consulting an oracle, Telephos was told that his wound might yet be healed, but only by him who had inflicted it. Having stolen Orestes from his cradle, by the advice of Clytæmnestra, he secured the aid of Agamemnon; and thus Achilleus was persuaded to heal Telephos by rubbing the wound with rust from the spear which had inflicted it. This revivifying power is ascribed to other mythical beings: thus, when PARIS is wounded by Neoptolemus, one legend says that Œnone whom he had deserted would not heal him; while another says only that she could not, although she longed to do so. This last tale is only a modification of the phrase, that Endymion must sink to sleep, even though Selênê is gazing on him.

Telescope (Gr. τῆλε, *afar off*, and σκοπέω, *I look at*). An optical instrument for viewing distant objects.

For several reasons a distant object is seen less distinctly than a similar near one. The angle which an object subtends diminishes as the distance increases; the density of light which renders it visible also diminishes with the distance, but in a much faster ratio; and a considerable portion of light is always lost in its passage through the atmosphere.

It is found by experience that to be discernible at all in ordinary daylight, a detached object must subtend at the eye an angle of not less than 30″, and that the least angle under which contiguous objects can be satisfactorily distinguished is about one minute. By the aid of a telescope, a magnified image of the object is obtained; and within certain limits the object is not only apparently enlarged, but rendered brighter than it appears to the unassisted eye.

The invention of the telescope, to which practical astronomy is indebted for its most important discoveries, has been ascribed to various persons. Sir David Brewster (*Ency. Brit.* art. 'Optics') says: 'We have no doubt that this invaluable instrument was invented by Roger Bacon or Baptista Porta, in the form of an experiment; though it had not, perhaps, in their hands assumed the maturity of an instrument made for sale, and applied to useful purposes, both terrestrial and celestial. If a telescope is an instrument by means of which things at a distance can be seen better than by the naked eye, then Baptista Porta's concave lens was a real telescope; but if we give the name to a tube having a convex object-glass at one end, and a convex or concave lens at the other, placed at the distance of the sum or difference of their focal lengths, then we have no distinct evidence that such an instrument was used before the beginning of the seventeenth century.' Descartes ascribes the invention to James Metius, a citizen of Alkmaer in Holland; Huygens to John Lippersey, or Zacharias Jansen; Borellus also to Jansen. Professor Moll, who has discussed these rival claims, after examining the official papers preserved in the archives at the Hague, comes to the conclusion that Metius (whose proper name was Jacob Adriansy) was, on the 17th of October, 1608, in possession of the art of making telescopes; but that from some unexplained reason he concealed his invention, and thus gave up every claim to the honour which he would have derived from it; that on the 21st of October in the same year, 1608, John or Hans Lippersey, a spectacle-maker of Middleburg, was actually in possession of the invention; and that there is little reason to believe that either Hans or Zacharias Zanz (or Jansen, father and son) were inventors of the telescope, though one of them invented a compound microscope about 1590. (*Journal of the Royal Institution*, vol. i.)

The telescope soon made its way into other countries. In April or May, 1609, the illustrious Galileo, having heard a rumour of the invention, set about considering the means whereby distant objects could be seen distinctly, and was soon in possession of a telescope which magnified three times. In subsequent trials he succeeded in increasing the magnifying power; and before the beginning of 1610, he had observed the satellites of Jupiter. Our countryman Harriot also, in 1609, began to use the telescope for examining the disc of the moon, and before he had heard of the discoveries of Galileo. (Priestley's *History of Discoveries relating to Vision, Light, and Colours.*)

Telescopes are of two kinds, *refracting* and *reflecting*: the former depending on the use of properly figured lenses, through which the rays of light pass; and the latter on the use of specula, or polished metallic mirrors, which reflect the rays; an inverted image of the object being formed in both cases in the focus of the lens or mirror.

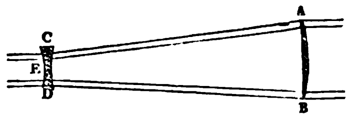
Refracting telescopes were those which were first constructed. They were of the most simple character, consisting merely of an object-glass of one lens, and an eye-glass of one lens,

but of a shorter focus. The action of a prism on a ray of light is familiar to all. It refracts it and sends it out of its course. A lens may be looked upon as an infinite series of prisms arranged symmetrically round an axis, and hence parallel rays falling on a lens are bent to a point called its *focus*. Such a lens we have in our eye, and at its focus lies the retina, on which a picture is painted. Now, a telescope is an extension of the principles on which our eye is constructed. In the eye a lens forms an image and we see; in the telescope one lens, called the *object-glass*, forms an image, and another lens, called the *eye-piece*, gathers up the rays from each part of the image, and transmits a parallel beam from each point to the eye. If only single lenses be used, the prismatic colours produced by the difference of refrangibility of the luminous rays tinge the images of all objects seen through the telescope, and the image is likewise distorted by the aberration of the extreme rays. It was soon found that the latter defects could be sufficiently corrected by employing more lenses than one in the eye-piece; but it was long before a remedy was found for the chromatic dispersion; and artists, despairing of success, generally turned their attention to the improvement of instruments of the reflecting class. The difficulty, however, was at length overcome through the persevering efforts of John Dollond [ACHROMATISM; OBJECT-GLASS]; and the *achromatic refracting telescope* may now be regarded as an instrument all but perfect.

The principles on which the action of telescopes depends having been explained under the terms REFLEXION and REFRACTION, and the properties and construction of their principal parts under ACHROMATISM, EYE-PIECE, LENS, MIRROR, and OBJECT-GLASS, we shall here describe some of the principal forms which the instrument has assumed. It will be borne in mind that the general aim in the construction of a telescope is to form, by means of lenses or mirrors, as large, bright, and distinct an image of a distant object as possible, and then to view the image with a magnifying glass in any convenient manner. Now, the brightness of the image depends upon the quantity of light. Thus, in the case of ordinary eyesight we use a beam of light about one-fifth of an inch (the aperture of the pupil) in diameter. As many times as the surface of an object-glass or speculum exceeds the surface of the pupil, by so many times is the light increased. The *distinctness* depends upon the purity of the material (in the case of the object-glass) and the correctness with which the rays are made to converge to a point. We will begin our notice of the various kinds of telescopes by describing those of the refracting class.

Galilean Telescope.—This is the most ancient form of the telescope, and is that which was used by Galileo. It consists of a convex converging object-glass, A B (fig. 1), and a concave diverging eye-glass C D. On passing through the object-glass A B, the rays of light coming from the different points of a distant object in sensibly parallel pencils are rendered convergent, and proceed towards the principal focus, where they would form an inverted image; but before

Fig. 1.

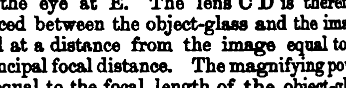


they arrive at this point they fall upon the concave lens C D, by which they are again rendered parallel, or at least their convergence is corrected so as to give distinct vision of the object to the eye at E. The lens C D is therefore placed between the object-glass and the image, and at a distance from the image equal to its principal focal distance. The magnifying power is equal to the focal length of the object-glass divided by the focal length of the eye-glass. [LENS.]

In this telescope the object is seen erect, and the length of the tube is only the difference between the focal lengths of the two lenses. These properties render it preferable to any other telescope for many ordinary purposes; as, for example, an *opera-glass*. When used for this purpose, the magnifying power is hardly ever greater than 4; and it is often as low as 2.

Astronomical Telescope.—This is composed (fig. 2) of a converging object-glass A B, and of a converging eye-glass C D. Rays of light proceeding from any point M of a distant object M N, and falling on the whole surface of the object-glass, are refracted into a point *m* in the

Fig. 2.



principal focus. In like manner, those proceeding from the point N are refracted into the point *n*: and thus an inverted image *m n* is formed at the focus of the object-glass. The eye-glass is placed so that its focus shall coincide with the place of the image: consequently rays diverging from any point of the image, and falling on the lens C D, are rendered parallel and enter the eye at E, and are thereby rendered fit to produce distinct vision. The length of the telescope is equal to the sum of the focal distances of the two lenses; and the magnifying power is equal to the focal length of the object-glass divided by the focal length of the eye-glass. This telescope was first described by Kepler in his *Dioptrice* (1611); but it does not appear to have been executed until about twenty or thirty years later.

Great strides have recently been made in the construction of the refracting astronomical telescope. At the present time (Jan. 1867), the largest of its class is being finished by the

eminent English opticians, Messrs. Cooke and Sons, of York. Its object-glass is of the enormous size of twenty-five inches in diameter. Mr. Alvan Clark, of America, has also recently constructed one of eighteen and a half inches. Till within the last few years almost all the most celebrated telescopes were constructed in Germany; and to give some idea of one of the finest existing instruments, we may describe the one in use at the observatory of Pulkowa. Its object-glass has a clear aperture of very nearly 15 inches, and its focal length is 22·5 feet. The length of the part of the tube between the object-glass and the declination axis is 13·7 feet, and that of the part between the eye-piece and the declination axis is 9·2 feet. The tube is of wood; it is of a conical shape, and the exterior diameters at the extremities are 17·0 inches and 11·8 inches. The telescope is furnished with six eye-pieces, whose powers vary from 152 to 1,218, and with other eye-pieces, twenty-one in number, belonging to the micrometrical apparatus with powers as high as 2,000.

The mounting is that known by the name of the *Fraunhofer mounting*, having the telescope on one side of the polar axis. The polar axis is nearly 4 feet in length, and the diameter of the horary circle is 18 inches, and is divided to 40″ of time. Sidereal motion is given to the telescope by clockwork.

The instrument was constructed by Messrs. Merz and Mahler, of Munich, and is in most respects similar to that erected at Cambridge, Massachusetts, near Boston, U.S., of which we also append a description.

The *Cambridge* telescope belongs to the observatory in connection with the Harvard university. It has not been erected many years, but it has already earned considerable fame by the discovery of some comets, of the crape ring and eighth satellite of Saturn, and by micrometrical observations (of great excellence and importance) of nebulæ.

The telescope and its equatorial mounting are the work of Messrs. Merz and Mahler. The extreme diameter of the object-glass is 15½ English inches, the effective aperture barely 15 inches, and the focal length 22 ft. 6 in. The mounting, like that of the preceding telescope, is that known as Fraunhofer's, i. e. the telescope is not in the plane of the polar axis, but on one side of it, supported near its centre at one extremity of the declination axis, and counterpoised by a weight beyond the other extremity of the declination axis. The declination circle is 26 inches in diameter, and is read by four verniers to 4″ of arc; the hour circle is 18 inches in diameter, and is read by verniers to single seconds of time.

Sidereal motion is communicated to the telescope by clockwork, regulated by the friction of centrifugal balls.

It is furnished with nine eye-pieces, whose powers vary from 103 to 1,118, and with a wire-micrometer eye-piece and position circle. The screw of the micrometer has been severely tested, and found to be of sensibly equal value throughout its length.

The whole aperture can be used without injury to the definition, and the discs of stars are remarkably small. In measuring double stars, powers from 700 to 1,200 have been habitually employed. On rare occasions, a power of 2,000 has shown well the discs of Neptune and of the satellites of Jupiter.

With powers of 700 and 800, stars have been separated whose measured distance has proved to be 0·3″. The satellites of Neptune and the inner and eighth satellite of Saturn are seen steadily, as well as the edge of the ring at what is called its disappearance. (*Description of the Observatory at Cambridge, Massachusetts*, by William Crouch Bond.)

The next telescope which we propose to describe is that called the *Northumberland telescope*, at the observatory connected with our own university at Cambridge. It may be taken as a specimen of what is termed the *English mounting*. The object-glass, by Cauchoix of Paris, is of 11½ inches effective aperture, and the focal length is 19½ feet. The telescope is in the plane of the polar axis, which is here represented by a series of supports parallel to it and supported at top and bottom. The hour circle is 5½ feet in diameter, and is not permanently attached to the polar axis, but can be clamped to or released from the lower iron frame at pleasure. There is no declination circle, but its place is supplied by a declination sector, i. e. a graduated arc carried by a flat brass bar nearly 6 feet in length, turning about a pin fixed in the telescope tube at the distance of rather more than 2½ feet from the axis of revolution of the telescope. This serves to measure small differences of declination. The instrument is provided with clockwork. The whole of the mounting was constructed under the direction of the Astronomer Royal, Mr. Airy. (*Cambridge Observations*; Airy's *Description*; Weale's *London Exhibited in* 1851.)

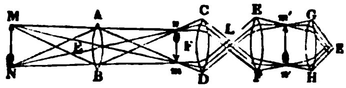
We give an illustration of the *Cooke mounting* (fig. 4), which is German in principle, though the details vary extremely from that construction of instrument. Telescopes of this kind, being generally used with a high magnifying power, and consequently having a small field of view, are always accompanied with a small telescope, or *finder*, fixed to the tube, so that the axes of the two instruments are exactly parallel.

Terrestrial Refracting Telescope.—This differs from the astronomical telescope only in having two additional lenses E F, G H (fig. 3), placed in the tube of the eye-glass for the purpose of restoring the inverted image to its erect position, and thereby accommodating the telescope to terrestrial objects. The focal lengths of these additional lenses are usually the same as that of the eye-glass. The two pencils of rays proceeding from the points M and N cross each other in the anterior focus of the second lens E F, and falling parallel on E F form in its principal focus an inverted image of *m n*, and consequently an erect image

of the object M N. This image $m' n'$ is seen by the eye at E through the lens G H, as the rays diverging from m' and n' in the focus of G H enter the eye in parallel pencils. When the first three lenses are equal, the magnifying power is the same as that of the astronomical telescope, whose object and eye glasses are the same as A B and C D.

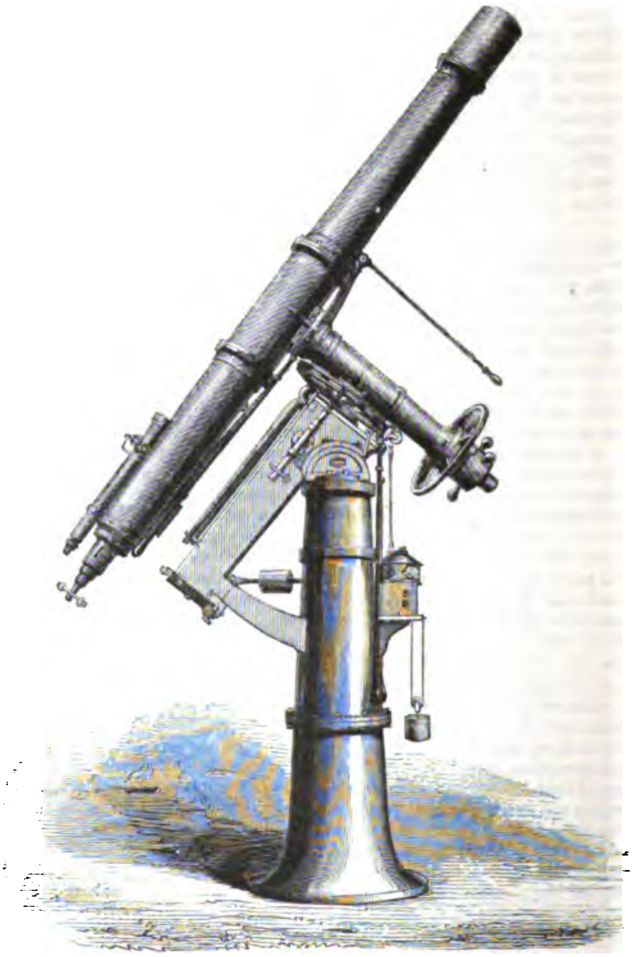
The performance of refracting telescopes depends most essentially on the perfection of the object-glass; for if the first image is bright and distinct, and perfectly achromatic, there is little difficulty in constructing eye-pieces to

Fig. 3.



magnify it, without causing it to undergo any sensible alteration.

Fig. 4.

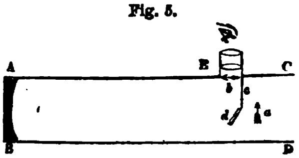


Reflecting Telescopes.—In reflecting telescopes, the speculum, or mirror, performs the office of the object-glass in those of the refracting kind, and is therefore called the *object-mirror*. The instrument is constructed in various forms; but these differ from one another chiefly in reference to the contrivances which have been adopted for bringing the focal image into a convenient situation for being viewed by the eye-piece. The principal forms are the Newtonian, the Gregorian, the Cassegrainian, and the Herschelian.

Newtonian Telescope.—Let A B C D (fig. 5) represent a section of the tube of the telescope: A B a section of the object-mirror, which would form at its focus the image a of any distant

object. Now, if a person attempted to view the image in its place at *a* by placing himself directly before the mirror, he would necessarily intercept the rays of light from the object

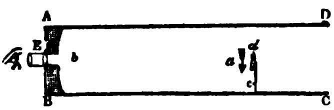
Fig. 5.



passing down the tube to the mirror, and consequently there would be no image to view. Sir Isaac Newton overcame this difficulty by introducing a small diagonal plane speculum *d* between A B and *a*, which, itself intercepting but a small portion of the light, reflects towards the side of the tube the rays converging from A B, and causes the image which would have been formed at *a* to be formed at *b*, where it can be conveniently viewed by the eye-piece E attached to the side of the tube. The small mirror is of an oval form, and is fixed on a slender arm *c* connected with a slide, by means of which it may be made to approach or recede from the large speculum A B, as the image approaches to or recedes from it. In this telescope the magnifying power is equal to the focal length of the object-mirror A B divided by that of the eye-glass.

Gregorian Telescope.—In this construction the object-mirror A B (fig. 6) is perforated in the middle, and the rays of light from a distant object being reflected from the surface of A B cross each other in the focus, where they form an inverted image *a*, and are then intercepted by a small concave mirror *d*, which causes them again to converge to a focus at *b*, near the perforation of the object-mirror, where they form a reinverted or direct image, which is viewed by an eye-piece E screwed into the tube behind A B. The curvature of the small speculum should be elliptical, having the foci at *a* and *b*; but it is generally made spherical. In this case the great speculum should be slightly hyperbolic, to counteract the aberration of the small mirror.

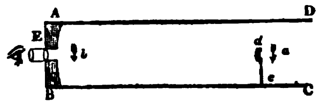
Fig. 6.



Cassegrainian Telescope.—The great speculum of this instrument is perforated like the Gregorian; but the rays converging from the surface of the mirror A B (fig. 7) towards the focus *a* are intercepted before they reach that point by a small convex mirror *d*, not sufficiently convex to make the rays divergent, but of such a curvature as to prevent them from coming to a focus till they are thrown back to *b*, near the aperture in A B, where they form an inverted image which is viewed by the eye-piece E. This construction has the advantage of requiring a shorter tube than the Gregorian; but the inversion of the image is not corrected, and for this reason probably it has not been much used.

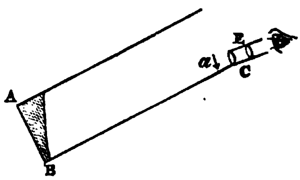
In the two last constructions the small mirror *d* is adjusted by means of a rod turning on a shoulder near the eye end of the tube, and connected by a screw with the apparatus which carries the arm *c* to which the mirror is attached.

Fig. 7.



Herschelian or Front-view Telescope.—This construction differs from the others in having no second mirror, and thus preventing loss of light by a second reflexion. The large speculum A B (fig. 8) is placed at the bottom of the tube in an inclined position, so as to bring the focal image *a* near the edge of the tube, where it is viewed directly by the eye-piece E without interfering much with the light entering the telescope from the object observed, but the image is a little injured by the oblique reflexion. The magnifying power is the same as in the Newtonian.

Fig. 8.



The reflecting telescope was invented by James Gregory, and is described by him in his *Optica Promota* (1663); but the first telescope of the kind was executed by Newton. The celebrated instrument of Sir William Herschel, erected at Slough in 1789, was 40 feet in length. Its great speculum had a diameter of 49½ inches; its thickness was about 3½ inches, and its weight when cast was 2,118 lbs. Its focal length was 40 feet, and it admitted of a power of 6,450 being applied to it. The essential advantage of large telescopes of this kind consists in the immense quantity of light which they collect, thus enabling the observer to perceive faint nebulæ and stars which are altogether invisible in ordinary instruments. For the more accurate kinds of work they are inferior to refractors, as it is almost impossible to obtain a perfect figure.

Reflecting telescopes are used only for observing *phenomena*. In order to derive full benefit from them, they must be used in the open air, and must either be mounted equatorially [EQUATORIAL] or else in such a manner

as to be capable of a smooth motion both in a vertical and horizontal direction.

Lord Rosse's 50-ft. Reflecting Telescope.—This enormous telescope, which has two mirrors of 6 ft. diameter, and is 53 feet in focal length, was begun in 1842. The metal used for the specula is an alloy of tin and copper in atomic proportions, the weight of the copper being something more than double that of the tin. The weight of metal in one of the specula is $3\frac{1}{2}$ tons, and that of the other 4 tons. For fusing these immense masses of metal it was placed in three iron crucibles cast expressly for the purpose, each crucible weighing of itself about $1\frac{1}{4}$ ton. The crucibles were placed in as many furnaces, whose mouths were level with the ground, and with flues opening into one common stack or chimney. The metal for its complete fusion required to be kept in the furnace about twelve hours, and when it was in the state proper for casting, the crucibles were withdrawn from the furnaces by means of a powerful crane to the iron cradles or pouring frames arranged round the mould at intervals of ninety degrees.

The mould had for its base a framework of hoop iron six inches in depth, placed edgewise, packed in a strong frame, and supported by strong transverse bars beneath. The upper edges of these were ground into a slightly convex surface of about 108 feet radius, and thus formed the base of the mould; allowing the air to escape through the interstices, though, from its viscosity, no particle of the alloy could escape through them. The metal also by being poured upon the iron became chilled immediately into a dense sheet of about half an inch thick, and thus secured one of the conditions which have been found to be most important, if not indispensable, in the casting of speculum metal. After becoming tolerably solid, the speculum was withdrawn to the annealing furnaces, where it remained for about sixteen weeks, when it was considered to be ready for the process of grinding and polishing.

A full account, given by Lord Rosse, of the polishing machinery will be found in the *Phil. Trans.* for 1840 and for 1861. It is sufficient to state that the beam carrying the polisher is moved by a small steam engine, by which a rotatory motion round a vertical spindle is given to a crank, which by a connecting rod acts upon a sliding rod which moves the grinder or polisher backwards and forwards. By such means the polisher makes strokes backwards and forwards very nearly in the manner in which the hand would make them, if the polishing were performed by hand, and at the same time another part of the machinery causes the frame carrying the speculum, and therefore the speculum itself, to revolve with a slow motion. We must remark further, in connection with this part of the subject, that it was necessary to cast and polish the speculum upon the same fixed frame (distinct from the rotatory frame before mentioned) that would support it when in the telescope. For this purpose the fixed frames are provided with small wheels, by which, after being conveyed in a carriage to a railroad running into the lower part of the tube of the telescope, the speculum is deposited in its proper position for use.

For the support of the mirror in such a way as to avoid strain and flexure, a very ingenious system of levers is employed. This consists of a combination of three similar systems, resting on three points under the centres of gravity of the three equal sectors into which the speculum may be supposed to be divided. Each system consists of one triangle with its point of support directly under its centre of gravity, upon which it freely oscillates. This triangle carries at its angles three similar points of support for three other triangles, under their centres of gravity, and they again at their angles carry in a similar way cast-iron platforms formed of three ribs, so as to make a kind of irregular open-work grating, supported under their centres of gravity. There are thus twenty-seven platforms, which are coated with greased cloth, and upon these the speculum is supported, each bearing $\frac{1}{27}$ of the weight.

The above is the construction first adopted by Lord Rosse. But, as the surface of the speculum by the pressure on its edge at different elevations was found to be distorted, instead of the platforms in contact with the back before mentioned there were adopted eighty-one brass balls capable of revolving freely, i. e. three at the corners of each triangle, occupying the place of the platform in the former construction.

We now come to the mounting of this immense speculum. The tube of the telescope is made of wood, and is at the middle about 7 ft. in diameter; the interior exceeding 6 ft. in every part. This is fixed to a cube of 10 feet, which has folding doors in one of its sides for admission of the speculum, and which carries the fixed frame supporting the mirror on the side opposite to the mouth of the telescope. To this side of the cube is attached a universal joint by which the lower end of the telescope is connected with a fixed support, the joint being a few feet below the general surface of the ground.

On the east and west sides of the telescope are immense piers about 70 feet long and nearly 50 feet high, of which the eastern carries a large iron arc of a circle, in which moves a slider attached to a racked bar working by means of a pinion carried by the telescope tube, while the other carries the stairs and galleries necessary for the observers. Near the tops of the piers in the east and west plane passing through the universal joint are two cranes with pulleys, over which pass chains attached to the telescope. To the ends of these chains, after they have passed through fixed pulleys in the walls, are attached counterpoises, weighing about four tons each. There is also a contrivance connected with the chains for equalising the action of the counterpoise-weights in different positions of the telescope.

By means of a rack and pinion, the observer, standing near the eye-end of the tube, is enabled to give a motion in hour angle of about half an hour on each side of the meridian position.

At the south end of the piers there are strong ladders, and upon these (assisted by counterpoises) there slides a stage upon which a small observing gallery travels backwards and forwards. For great elevations, curved galleries are mounted upon the curved slope of the upper part of the western pier, carried by beams running above and below pulleys fixed to the top of the pier; they are run out by rack-and-pinion work to approach the side of the telescope.

A quick motion in declination is given by the windlass below, and a slow motion is given by hand above for measurements: the quick motion in right ascension is given also below by a wheel turned by a workman, and the slow motion by hand above.

The tube is slung by chains, and is perfectly steady in a gale of wind. It carries at the upper extremity the apparatus for the Newtonian small mirror, which is itself of considerable size and weight, the minor axis of its ellipse being about 6 inches; but Lord Rosse has made provision in the construction of his observing galleries for using it as a Herschelian telescope, if it is found necessary or desirable to obtain an increase of light.

In the use of this wonderful instrument, Lord Rosse has hitherto confined himself chiefly to the observations of nebulæ.

Reflecting Telescopes with silvered Glass Specula.—Recently, Steinheil of Munich and Foucault of Paris have successfully constructed specula of glass which, after polishing and figuring, receive a film of pure silver, deposited by chemical means upon their figured surfaces. This film does not exceed $\frac{1}{12,000,000}$ of an inch in thickness, but according to Steinheil it reflects, when polished with rouge, 90 per cent. of the light falling upon it, whilst speculum metal reflects only about 63 per cent. Another advantage connected with glass specula is that a good figure when once produced is permanent, since it is not altered either by the deposition or subsequent polishing of the silver film, whereas the figure of a metallic speculum is liable to serious alteration at every polishing. Thus there is every encouragement to bestow great labour upon the figuring of a glass speculum. Several small telescopes upon this principle have been constructed in this country. One of them, of 7 inches aperture, and with a power of 270, divides with ease and certainty the very close double star η Coronæ.

Eye-pieces of Telescopes.—When the image formed by the object-glass or mirror is viewed with a single lens or eye-glass, whether concave or convex, it is only in the centre of the field that distinct vision is obtained, all towards the margin being hazy and distorted. To remedy this defect, Boscovich and Huygens independently proposed the construction of an eye-piece formed of two lenses, placed at a distance from each other equal to half their focal length. Boscovich recommended two similar lenses: Huygens, that the focal length of the one should be twice that of the other: and as this construction is found to answer best in practice, it is that which is most commonly used.

The two lenses are usually plano-convex, with the convex faces towards the object-glass; the larger lens, called the *field-glass*, is innermost, or nearest the object-glass: and a diaphragm cutting off the marginal rays is usually placed between them near the focus of the eye-lens, where the image is formed. This eye-piece is usually called the *negative* eye-piece, from its having the image seen by the eye behind the field-glass; and is that which is commonly supplied with telescopes intended only for the purpose of *seeing* objects, without reference to measurement.

Another modification of the two-lens eye-piece was proposed by Ramsden, and is called the *positive* eye-piece, because the image observed is before both lenses. The lenses are plano-convex, and nearly of the same focal length; but their distance from each other is less than the focal distance of the lens nearest the eye, two lenses thus placed acting as a compound simple lens. This eye-piece is the most convenient when micrometer wires are placed in the focus, because it can be taken out without injuring the wires; and it has also this advantage, that the measure of an object given by one eye-piece is not altered when it is changed for another of a different magnifying power.

In both the eye-pieces now described, the image is seen inverted; and though this is of no importance in astronomical observations, it is inconvenient when the telescope is used for looking at terrestrial objects. By placing an additional pair of lenses in the tube of the eye-piece, the image is repeated and reinverted, and consequently seen erect. By this means, as explained above, the terrestrial telescope is obtained.

The name of *diagonal eye-piece* has been given to eye-pieces furnished with a diagonal reflecting mirror, the object of which is to give a more convenient direction to the rays emerging from the eye-piece when the telescope is pointed high. [Eye-piece.]

Telescopes are generally supplied with eye-pieces of different powers, which are all fitted to enter the same tube: and the focal adjustment is commonly effected by a rack-and-pinion motion acting on the tube which carries the eye-piece.

For full information respecting the construction of telescopes, and the best modes of mounting them, to secure steadiness and allow of the requisite motion, the reader is referred to Pearson's *Practical Astronomy*, vol. ii. [Alt-azimuth; Eye-piece; Object-glass; Transit Instrument.]

Tell-tale. On Shipboard, the dial plate at the wheel, showing the position of the tiller.

Teller of the Exchequer. A very lucrative sinecure office, abolished by stat. 4 & 5 Wm. IV. c. 15. In 1780, the emoluments of each teller for the exchequer, exceeded 7,000*l.* a year, and the offices became still more valuable in subsequent years.

Tellina (Gr. τελλίνη, *a species of muscle*). A genus of cockles (Cardiaceous Bivalves in the Cuvierian system), characterised by the hinge of the shell having one tooth on the left and two teeth on the right valve, often bifid; in the right valve there is a plate which does not enter a cavity in the opposite valve. There is a slight fold near the posterior extremity of both valves which renders them unequal at that part, where they gape a little. The soft parts, or animal of the *Tellina*, called *peronæa* by Poli, has two long tubes for respiration and excretion, which can be withdrawn into the shell, and are concealed in a fold of the mantle.

Cuvier separated from the Linnæan *Tellinæ* the genus *Loripes*, distinguished by the feebly developed cardinal teeth, and by a long cylindrical foot. Other genera have since been detached from the Cuvierian *Tellinæ*, which now form a family, *Tellinidæ*, in the system of Lamarck.

Tellurbismuth. A native telluride of lead and bismuth, found only at Field's mine in Georgia, and at the Tellurium mine, Virginia, U.S.

Tellurism (Lat. tellus, *the earth*). A name given to the system of magnetism put forth by Kieser, who substituted the idea of a telluric spirit in place of the universal fluid of Mesmer and the nervous atmosphere of Kluge. This tellurism was not confined to the substance of the earth, but extended to other bodies also. Thus, the moon was said to magnetise the inhabitants of the earth by night, while the sun demagnetised them in the morning. [MAGNETISM, ANIMAL; SOMNAMBULISM.]

Tellurite or **Telluric Ochre.** Native oxide of tellurium. It occurs in small spherical masses with a fibrous radiated structure, at Facebay and Zalathna in Transylvania.

Tellurium (Lat. tellus). This rare metal has only been found in small quantities in the gold mines of Transylvania: it occurs in the metallic state, combined with gold or silver. It is white, brilliant, brittle, and easily fusible. Its specific gravity is about 6·25. It is combustible, and exhales a peculiar odour, like horse-radish, which Berzelius ascribes to the presence of minute portions of selenium. Its atomic weight is 64. It forms a series of compounds resembling those of sulphur and selenium, as hydrotelluric acid HTe, anhydrous tellurous acid TeO_2, hydrated tellurous acid HO,TeO_2, anhydrous telluric acid TeO_3, hydrated telluric acid HO,TeO_3, a chloride and bichloride TeCl and $TeCl_2$, and also a bisulphide TeS_2 and a tersulphide TeS_3.

Tellurium Glance. [NAGYAGITE.]

Telphusa (Gr. Τελφοῦσσα). In Greek Mythology, a daughter of Ladon, who gave her name to a fountain near Haliartos. But in the so-called Homeric hymn to Apollo, she appears rather as the fountain itself than as the nymph of the fountain. In that hymn Apollo is represented as exciting her anger by marking out a place for a temple to be built to himself, and laying its foundations: and Telphusa, to avert the danger threatening her waters, advises him to go on to Crisa, where he slew the dragon Python who nursed Typhaon, the child of HERA.

But Apollo, finding that he had been lured into a desolate land, returned full of wrath to Telphusa, and, hurling down great stones, choked the waters of the fountain for ever.

Tempera Painting. [DISTEMPER.]

Temperament (Lat. temperamentum). In Music, the adjustment of the notes in musical instruments whose sounds are fixed, such as organs, pianofortes, &c. The defect to be remedied arises from the single short keys between the two larger ones serving for flats as well as sharps. It is necessary to observe, that in the theory of harmonies the interval of a tone is not always the same; for instance, that lying between the fourth and fifth of the scale contains nine small parts, called *commas*, whereas that between the fifth and sixth of the major scale contains only eight commas. Again, the diatonic semitone contains five commas, and the chromatic semitone three or four, according to the magnitude of the tone. Hence it is that the different situation of these elements with regard to each other causes intervals of the same names to consist of different degrees or elements. To improve them, therefore, musicians *temper* them so as to reduce the whole more to mean distances from each other, necessarily producing a new division of the octave. Pianofortes are generally tuned on what is called *equal temperament*, i.e. there being eleven notes in the octave, an equal value is given to each interval between them representing a semitone. The consequence of this is that although all the intervals, the thirds, fifths, &c., are slightly imperfect, yet they all approach perfection in the same degree; whereas if some of them were made accurate, others must be very far wrong.

TEMPERAMENT. In Physiology, temperament has been defined as that peculiarity of organisation which to a certain extent influences our thoughts and actions. The ancient physicians enumerated four temperaments; viz. the *bilious* or *choleric*, the *phlegmatic*, the *sanguine*, the *melancholic*. To these some have added the *nervous*; and these terms are still in use among medical writers.

Temperance Societies. According to a statement made at the meeting of the 'World's Temperance Convention' at New York in 1853, the first *National Organisation against Alcohol*, i.e. the *American Society for the Promotion of Temperance*, was established in 1826. Societies of persons pledged by mutual agreement to abstain from intoxicating drink were formed about the same time both in Britain and

America, and differences of opinion as to the strictness of the rules to be followed engendered the different designations of *temperance* and *total abstinence* or *teetotalism*. But the movement may first be said to have become popular, on this side of the Atlantic, through the extraordinary exertions of the Irish priest, Father Mathew, one of those rare men to whom the faculty of kindling popular enthusiasm is given in the highest degree, and one who never abused it for ordinary or personal motives. (Maguire's *Life of Father Mathew*.) He began his preachings at Cork, in 1833, and in a very few years had obtained an extraordinary success. In five months, 131,000 persons took the *pledge* of total abstinence which he tendered to them: and when he travelled round the island, these numbers rose to almost fabulous proportions. But the zeal thus kindled had already died out even before the early decease of its excellent originator. The friends of the temperance movement in America appeared to have achieved a greater success when the state of Maine passed, in 1851, a law *for the suppression of tippling shops*, &c. rendering penal the sale of intoxicating drinks. But the 'Maine Law,' though subsequently adopted by some other states and in the British colony of New Brunswick, is said to have become in a few years a dead letter. The more recent effort of the partisans of the cause in this country has been to persuade the legislature to pass a *permissive* enactment, under which the authorities of any district, with the assent of the majority of the people, should be enabled to close the public-houses. The propagation of these views has been carried on chiefly by the *Alliance for the Suppression of Traffic in Intoxicating Liquors*. It was said, about 1850, that 3,000,000 persons had taken the pledge of total abstinence, of whom 50 per cent. were supposed to have broken it. (See *Edinburgh Review*, vol. c., for a history of the movement down to 1854: its history from that time to the present day presents no new features, and calls for no further comment.)

Temperate Zones. In Geography, two of the five zones into which the terrestrial globe is divided. The *north temperate zone* is included between the tropic of Cancer and the arctic circle; and the *south temperate zone* between the topic of Capricorn and the antarctic circle.

Temperature. The amount of heat in a body perceptible to the senses, measurable by a thermometer, and capable of being transferred to another substance. The following tables of various temperatures contain determinations of general interest. The first table gives the fusing points of the most important metals, according to the pyrometric measurements of the different experimenters named at the head of each column; the least reliable numbers being those in the first column. The second table contains the melting points of the more fusible metals, with some remarkable and extreme temperatures, the name of the authority being generally appended. In both tables the degrees are Fahrenheit, those below zero having a minus sign (—) prefixed.

Tempering. A term applied to the process by which the hardness of steel is more or less reduced. [Steel; Steel Guns.]

Templars or **Knights of the Temple.** A military religious order. It was founded by an association of knights, in the beginning of the twelfth century, for the protection of pilgrims on the roads in Palestine: afterwards, it took for its chief object the protection of the Holy Sepulchre at Jerusalem against the Saracens. Knights were fixed at Jerusalem by King Baldwin II., who gave them the ground on the east of the Temple. Their rules, taken from those of the Benedictine monks, involved the vows of chastity, obedience, and poverty. The classes of the order were, knights, esquires, servitors, and chaplains; the universal badge of

the order was a girdle of linen thread. The officers of the order were chosen by the chapter from among the knights; they were, for military affairs, marshals and bannerets; for purposes of government, priors, who superintended single priories or preceptories; abbots, commanders, and grand priors, who governed the possessions of the order within separate provinces; and the grand master, who, in some respects, assumed the dignity of a sovereign prince, being independent in secular matters, and depending solely on the pope in spiritual. The chief part of the 9,000 estates, lordships, &c., which the society possessed in the thirteenth century, was situated in France; and the grand master was usually of that nation. The Templars, with the rest of the Christians, were driven from Palestine by the Saracens, and then fixed the chief seat of their order in Cyprus. Their exorbitant power and wealth, and the haughty manner in which they endeavoured to keep aloof from the control of European sovereigns and act as a military republic independent of their authority, were probably the principal reasons which induced Pope Clement V. and Philip the Fair of France to concert their overthrow. The charges of heresy and idolatry, which were preferred against them, were at least unsupported by evidence. In 1307, Jacques de Molay, the grand master, having been enticed into France, was arrested by Philip; the estates of the order were seized; many of the Templars were burnt alive, after the mockery of a trial; and, in 1312, the order was abolished by a bull of Clement V. Its vast estates fell partly into the hands of the sovereigns of the countries in which they were situated, partly into those of the Hospitallers and other military orders. Detached bodies of the order, however, continued to subsist for some time in different countries. See, among numerous authorities, Raynouard's tragedy of *Les Templiers*, with the notes; Turner's *England in the Middle Ages*, vol. ii.; *Mém. de l'Acad. des Inscr.* vol. xxxvii.; Addison's *History of the Knights Templars and the Temple Church*, 1842; Milman, *History of Latin Christianity*, book xii. For a notice of the strange irreligious doctrines attributed to them, see the article BAPHOMET.

Temple (Lat.). Like the Greek τέμενος (from τέμνω, *to cut*), this word meant originally any piece or portion cut off from a whole; and the limitation of the name to buildings is of comparatively late date. Thus Livy (i. 6), using the word in the sense of an open space, speaks of Romulus and Remus as taking temples for the purposes of augury on the Palatine and Aventine Hills; and by Lucretius and Cicero the term is applied to the expanse of the heavens, or to the space in which the globe of the earth moves. In a religious sense, the word denotes properly a sacred enclosure, which may or may not contain buildings, this enclosure having reference to the portion of sky within which the omens were to be observed by the augurs. Those places only which had thus obtained the sanction of the gods were strictly temples; edifices consecrated only by man, as by the pontiffs, were called *sacella* or chapels, and thus the sanctuary of Vesta was only an *ædes sacra*, not a *templum*. By the Latins the ground lying beyond this enclosure was regarded as profane; by the Greeks it was termed βέβηλος, as being ground on which everyone might walk. Within the enclosure, as a rule, no dead might be buried, and this rule was extended to the whole of the sacred island of Delos [ORTYGIA], which was regarded as the τέμενος or sacred portion of PHŒBUS.

The earlier Greek temples were made chiefly of wood, and were at first little more than hollowed trunks of trees in which some image or symbol of a god was inserted. The form of the later temples was oblong, and they were generally surrounded with pillars, the parallelogram being divided into two parts, the πρόναος, or vestibule, and the cella, or ναός, the proper habitation of the god, to which was added in temples of the largest class the OPISTHODOMUS, which commonly served as a treasure chamber. The small size of the abodes in which the images of the gods were placed characterised all temples, and especially marked those of Egypt. Most of the temples still remaining in Attica, Ionia, and Sicily, have their entrances to the east, although it is stated by Vitruvius that Greek temples always faced the west. For the images of the gods placed in these buildings, see SCULPTURE.

Vitruvius classified quadrangular temples as temples: 1. IN ANTIS; 2. PROSTYLE; 3. AMPHIPROSTYLE; 4. PERIPTERAL; 5. DIPTERAL; 6. PSEUDODIPTERAL; and 7. HYPÆTHRAL. But it is not easy to determine in all cases whether a temple was hypæthral or not, and this is especially doubtful in the case of the Parthenon on the Athenian ACROPOLIS. Among other celebrated temples were those of Zeus at Olympia, of Artemis at Ephesus, of Apollo at Delphi, of Aphroditê at Paphos, and of the Capitoline Jupiter at Rome. A circular form for temples was adopted in some instances, but not in the earlier times, the oldest examples of round buildings being probably mere *tholi*, or monumental edifices. Among circular temples, those of Vesta at Tivoli and the Pantheon at Rome, still used as a church, are the best known.

In many, perhaps originally in all, nations, the first objects set up, whether for veneration or merely as symbols, seem to have been conical figures, sometimes in the form of single stones, sometimes in the shape of heaps or mounds. Thus, Jacob is represented as setting up a stone before he goes to rest in the evening. That these stones were in many cases symbols of the reproductive power of nature, is admitted on all hands; and the same figure was seen in the Ashera set up in the temple at Jerusalem [PHALLUS], and in the Brahmanic LINGAS, with which the ROUND TOWERS of Ireland, and other edifices of a like character, are by some connected.

The plan of the temple of Jerusalem, specially known as the temple of Solomon, is, like the plan given in the descriptions of the tabernacle, not unlike that of Greek temples, the cella being represented by the Holy of Holies. The temple of Solomon, built in great part by Phœnician workmen, sent by Hiram, king of Tyre, was destroyed by Nebuchadnezzar. The temple which succeeded it, after the return of the Jews from Babylon in the time of Cyrus, continued to the days of Herod the Great, who began repairs which amounted almost to a complete rebuilding. This restoration was scarcely finished when the city was destroyed by Titus. For the controversies on the subsequent history of the buildings contained in the temple area, see SEPULCHRE, CHURCH OF THE HOLY.

Templet or **Template.** In Architecture and Engineering, a short piece of timber, or stone, laid under the bearing of a girder, with the object of distributing the weight of the latter. Also, a mould used by bricklayers, masons, &c. for cutting or setting out work; or by millwrights, for cutting the teeth of wheels. Also, any plate or board formed to the exact dimensions of parts of engines and machines, so that new parts may be produced from such templets of the exact size required to fit the other parts.

TEMPLET. In Artillery, an iron plate, one side of which is made to correspond exactly with the correct exterior of an elongated shot or shell. It is used as a gauge.

Tempo (Ital. *time*). In Music, the Italian word constantly used to express time.

Tempo d'Imbroglio (Ital. *time of trouble*). In Music, a term applied to a composition written in one measure, but really performed in another.

Temporal or Temple Bones. Two irregular bones, one on each side of the head. They are connected with the occipital, parietal, and sphenoid bones, and are articulated with the lower jaw. Comparative anatomy shows that the so-called *temporal bone*, in man, is essentially an assemblage of five bones, called squamosal, zygomatic, tympanic, petrous, and mastoid; having distinct functions developed in different proportions, and continuing permanently detached in the cold-blooded classes, but soon coalescing in the warm-blooded classes. The tympanic element, however, continues permanently detached in birds.

Tenacity of the Metals. The power which metallic wires possess of sustaining, without breaking, the action of a suspended weight. [COHESION; STRENGTH OF MATERIALS.]

Tenaculum (Lat. *a tie*). A surgical instrument, consisting of a fine sharp-pointed hook, by which the mouths of bleeding arteries are seized and drawn out, so that in operations they may be secured by ligatures.

Tenaille (Fr.). In Fortification, a small work placed before the curtain, and intended to secure it and the flanks against being breached, which would render retrenchments in bastions useless. [FORTIFICATION.]

Tenaillon (Fr.). In Fortification, an outwork made on each side of a small ravelin to increase its strength, and to cover the shoulders of the bastion. Works of this kind are, however, so defective that they are not now adopted.

Tenancy in Common. In Law, tenancy in common occurs when property is given or conveyed to two or more persons in undivided shares, each share being distinct in title. In this case there is no right of survivorship as in joint tenancy (which indeed a tenancy in common resembles in the unity of possession only), but each tenant in common is, as to his own undivided share, in the position of the owner of a separate estate. Any tenant in common may compel a partition of the property held in common.

Tenant, Tenement (from Lat. teneo, *I hold*). In Law. These words are derived from the principles of the feudal system, according to which (as it prevailed in England) no land was without a lord; and everyone who enjoyed land *held* it either of a mesne tenant, or of the crown. The party holding the land is called *tenant*; the thing holden, *tenement*; the mode of holding, *tenure*. Thus, tenants are said to be in *fee simple, in tail, for life, for years*, &c. Tenement, in the largest sense of the word, is everything which may be holden; viz. all corporeal hereditaments, and incorporeal hereditaments of a permanent nature issuing out of the same. Thus, lands, houses, rights of common, &c., franchises, dignities, are all tenements in the larger sense. In the more narrow acceptation in which the word is popularly applied, it describes a house with the homestead or immediate appurtenances. [TENURE.]

Tenant Right, &c. The social question involved in the demand for *tenant right* is one which has now agitated Ireland for at least a century. It is the chief cause of that deep-seated disaffection towards political association with England which all admit to be the characteristic feeling of the Irish, and exhibits in the plainest and harshest form the discord which may arise between the owner of the soil and its occupier. The distribution of land in the United Kingdom, by which a few proprietors hold the greater part of the soil, while the cultivator has only a precarious interest on payment of a variable rent, is, it must be remembered, peculiar to this country. [RENT.] As the English and Scotch farmer is generally a considerable capitalist, and the farmers as a class are tolerably united, and, as individuals, very independent, the precarious nature of their holding is more apparent than real. Nominally, the farmer, in the great majority of cases, is a tenant at will; actually, he is a permanent occupier at a variable rent. If he makes improvements, the landlord may, in theory at least, cause him, by raising his rent, to pay interest on the outlay of his own capital. In practice, however, while many improvements are effected

by wealthy landlords, public opinion would, in the vast majority of cases, prevent the landlord from taking so unfair an advantage when the improvement was the work of the tenant. Besides, agriculture is only one, and that a comparatively subordinate, part of the industry of Great Britain, and the influence of landowners is to some extent counterpoised by that of other and equally wealthy classes. Lastly, rents are not raised or depressed by competition, the common practice being to fix the rent, and select the tenant, when vacancies occur.

In Ireland the case is very different. Agriculture, and that of a very rude and imperfect kind, is the general occupation of the people. The farms are very small, the tenants not being much above the condition of ordinary labourers, and, in appearance at least, being possessed of very little capital. Much land in Ireland is possessed by non-resident proprietors, who manage their estates by middlemen or bailiffs; and up to comparatively recent times, the resident proprietors — the picture of Irish society in *Castle Rack-rent* is said to be by no means over-coloured—were proverbially thoughtless, extravagant, and reckless. Rents were fixed by auction, and in the absence of any other occupation, and under the pressure of a redundant population, the competition for holdings raised rents nominally to an extravagant height, cottiers agreeing to pay sums which were far in excess of the value to be obtained from the annual produce of the soil, and, of course, being perpetually in arrears with their landlords. This state of things led to attempted evictions, to the murder of bailiffs and other agrarian outrages, the people invariably siding with the criminal, concealing him, and aiding his escape. Absentee proprietors, unimproving landlords, cottier tenancies, did, and to a great extent do still, characterise a country the peasantry of which, more perhaps than those of any other country, are capable of affection towards their social superiors, while they need the aid of capital for developing the resources of the soil, together with the advantage derived from fixity of tenure, in order to be encouraged in applying such means as they may themselves possess. It may be added, too, that most of the great proprietors are aliens to the Irish in descent, in national sympathies, and in religious belief. The creed professed by the great mass of the Irish people, though not now persecuted, was grievously oppressed, during the seventeenth and eighteenth centuries, the harshest and most cruel wrongs having been inflicted by men of Irish descent who had identified themselves with the political Protestantism of the period. (Goldwin Smith's *Irish History and Irish Character*.)

Much, no doubt, of Irish disaffection is to be traced to the history of land tenure in that island. The first adventurers who settled in Ireland, and indeed the English adventurers for many generations afterwards, found the native Irish in possession of a peculiar land law, called the Brehon. The soil was owned by the sept in common, the chief being appointed by the custom of TANISTRY, and the usufruct of the land being distributed according to the custom of Irish gavelkind. The Norman settlers, and after them the English colonists, down at least to the time of Strafford's regency, attempted in vain to import the English law, with its system of feudal dependence, primogeniture, and entails. The Irish, however, gained on them, and, with the peculiar power said to be possessed by Celtic races, induced their visitors to adopt Irish customs, much to the dissatisfaction of the English government. But successive settlements, the enormous forfeitures created after O'Neil's rebellion, the grants of Cromwell, William III., and subsequently the penal statutes against Roman Catholics, led gradually to the adoption of the English feudal law, and the consequent destruction of those qualified but intelligible rights which the ancient peasantry possessed in the sept or village system of the Brehons. The Irish peasantry are to this day alive to the process by which their ancient interests have been annulled, and are profoundly disaffected at the result.

Gradually (perhaps as a compromise with the peasantry), the right of a tenant in his lease, and his claim for compensation when he had by his own labour or capital effected, independently of the landowner, permanent improvements on his holding, were recognised in Ulster, and have been so often admitted that they are probably legal. Great part of Ulster was granted to the city of London, and it is possible that the corporation was either from choice or necessity a more generous landlord than the other settlers. But the privilege accorded to the Ulster tenant has been persistently claimed by the farmers in the other provinces, as yet unsuccessfully, but with increasing energy. On the other hand, the landowners are disinclined to concede rights which would ultimately reduce them to the position occupied by the possessor of a perpetual fee-farm rent, and transfer the real ownership of the soil to the peasantry.

It cannot be doubted that the claims of the Irish peasantry are directly at variance with that theory of English law, with which we are familiar under the name of the law of real property. It is quite another thing to say that this law is in accordance with public policy, still more to assert that rules which may work well in England are available for the Irish people. The solution of the question is difficult, but it ought not to be impossible. It is quite certain that the Irish land system has produced most of that Irish disaffection which, dangerous as it is at home, is far more dangerous on the American continent.

Tenasserime. [TREMENHEERITE.]

Tench (Fr. tenche, Lat. tinca). The name of a species of Cyprinoid fishes (*Tinca vulgaris*, Cuv.), and the type of a subgenus of that family. It is generally more or less abundant in ornamental waters and ponds, but is seldom found in rivers in this country. It is common in most

of the lakes of the European continent, whence it is supposed to have been imported into England. The tench is remarkable for its tenacity of life; it spawns about the middle of June, at which time the female is attended by two males. Their food consists of the smaller soft-bodied aquatic animals, and vegetable matter. In stocking a pond with tench, the large-sized fish should be selected, and two males to one female should be the proportion of the sexes. [TINCA.]

Tender (Fr. tendre; Lat. tendo, *I stretch* or *hold forth*). In Law, the legal tender of a debt is by the actual production and offer of the sum due, unless the creditor dispense with it by a declaration that he will not accept it. The tender must be of money; and, if beyond the sum of 40*s*., in gold, or in what has been rendered by Act of Parliament equivalent for that purpose, viz. bank of England notes, which are a legal tender for every sum above 5*l*., except at the bank of England or its branches. The tender of a larger sum than that due is sufficient, but the creditor cannot be required to give change.

TENDER. A Naval term for a small vessel appointed to attend upon a larger one, to communicate with the shore, &c. It sails in company, but may be sent on expeditions up rivers, &c. where its patron could not penetrate.

Tendo Achillis (Lat.). The large tendon which passes from the muscles of the calf of the leg to the heel. Its name has reference to the fable of the dipping of Achilles in the Styx; his mother, Thetis, having, as it is said, held him by that part.

Tendril (Fr. tendron). In Botany, any slender twining or clasping part or organ by which a plant attaches itself to some other object. It is often a transformation of a leaf which has no lamina, or of which the midrib, elongated beyond it, retains its usual tapering figure, and becomes long and twisted spirally. In the vine it is an abortive bunch of flowers; in the passion flower, a metamorphosed branch. The leafstalk sometimes serves the purpose of a tendril, as in the *Tropaeolum*.

Tenesmus (Gr. τείνω, *I stretch*). An inclination and ineffectual straining to void the contents of the bowels.

Tennantite. A sulphide of copper, arsenic, and iron; named after Smithson Tennant. It occurs in lead-grey crystals at Carn Brea, Dolcoath, Cook's Kitchen, Tincroft, and other Cornish mines; also at Skeelteren, in Norway, and in Algeria.

Tenné, Tawney, or **Brusk.** In Heraldry, a colour or tincture, represented in blazonry by crossing lines horizontal and diagonal from left to right downwards. [HERALDRY.]

Tennis. A game, in which a ball is kept in motion between opposite parties, who strike it with rackets.

Tenon (Lat. teneo, *I hold*). In Architecture, the end of a piece of wood or timber, diminished usually by one-third of its thickness, which is received into a hole corresponding to it in size, called a *mortise*, by which expedient the two are held jointed or fastened together.

Tenore or **Tenor** (Ital.). In Music, that part of a vocal composition which is sung by a high male voice.

Tenorite. A native protoxide of copper, which is found at Vesuvius in the form of small dark steel-grey laminae, also earthy and as a black powder. Named after Signor Tenore.

Tenrec. The name of a small insectivorous quadruped of Madagascar, allied to the hedgehog; it forms the type of the genus *Centetes*.

Tense (Lat. tempus, *time*). In Grammar, that modification of the verb which defines the time at which the action is conceived as taking place.

In the Aryan languages, the tenses are formed chiefly by combining the verb substantive with the root of the so-called verb active, passive, middle, or neuter. Thus the *future tense* is formed, in Greek, by the addition of *s*, belonging to the root *as*, to be, and the Latin by adding the root bhu, *to be*. The present tense is simply the name expressive of action or endurance, combined with the personal or demonstrative pronoun, thus δίδωμι = dadâmi = *give I*. The imperfect, in Greek, is formed by placing, before the root of the present, a prefix termed the *augment*. This augment Bopp regards as identical in its origin with the *a privative*, and as expressing therefore the negation of the present, as in Sanscrit uttamas is *the highest*, anuttamas (not the highest, and so removed beyond comparison, i. e.) *incomparable*; êka, again, is *one*, but anêka answers not to οὐδείς, *none*, but to 'not *one*,' i. e. *many*. Thus the Greek syllabic augment ε-τερπ-ον represents the Sanscrit a-tarp-am; and the explanation is found in the fact that this *a*, which at a later stage acquires a privative force, is really the demonstrative base *i* or *e*, as in the Sanscrit enâm, the Latin *enim*. Thus the augment would not deny the presence of an action, but, meaning simply *that*, i. e. 'not *this*,' it would transfer the action to the other side, in other words, to the time already past. No argument can be drawn from the circumstance that in Greek the negative appears always as *a*, the augment always under the form ε, as τέτυφα and τέτυφε both represent the Sanscrit tatôpa.

Like the future, the Greek aorist is formed by combination with the radical consonant of *as*, to be, as in ε-τυπ-σ-α, ἔτυψα.

The Latin aorist or preterite is formed after the same fashion, the combined root being that of *fu*, or *bhu*, to be, e.g. pot-ui, for pot-fui, the same suffix reappearing in *ama-vi*, *audi-vi*.

The older Latin futures are formed like the Greek, e. g. fac-s-o (faxo), as τυπ-σ-ω (τύψω). In French, the future is formed by using as a suffix the verb *to have*; in the old Norse dialect it is formed by means of *mun*, I think [MENU], e. g. komamunu, *they will come*, i. e. they *mean* to come, thus reproducing the Greek μέλλω, Sanscrit manyâ, *to mean*.

Forms apparently anomalous occur in some tenses; thus the Latin *amamini* is out of all analogy with the other passive persons, but is

explained on a comparison with the Greek participial form τετυμμένοι, although it differs from the latter in having renounced its gender and its verbal suffix. The same participial formation is seen in such nouns as *alu-mnus*, *vertu-mnus*, ge-mini = genimini, γενομένοι, *the twins*, i.e. those who are *born together*. The Latin *amaminor* is a plural case-ending of *amamini*, as in the EUGUBINE TABLES, *subator* occurs for the Latin *subacti*, and *screbitor* for *scripti*.

Latin preterites, such as *cucurri*, *tutudi*, have lost their augments, like the Greek ἔπεφνον, for ἐπεφενον. Preterites, such as *fugi*, *legi*, *fodi*, have, further, lost their reduplication, the vowel being lengthened to make up the loss of the consonant of the second syllable, as in the Greek aorists ἔφηνα, ἔψηλα, for εφανσα, εψαλσα.

The verb substantive reappears also in such terminations as the Greek ευω (δουλεύω representing an original δουλ-φευω, to *be* a slave, as the Latin potui is really *pot-fui*, I *was* able), and in the Latin form bundus, such words as *vitabundus*, *mirabundus*, having retained the participial force, as in the phrases vitabundus castra, mirabundus vanam speciem. The anomalous Latin futures of the third and fourth conjugations, as *audiam*, are simply present tenses of the subjunctive mood, used in place of the lost futures, as *audibo*.

The same suffix reappears in the Latin infinitive, as in the present pos-se, velle = vel-se; esse, *to eat* = ede-re; ferre = fer-se, φέρειν, *to bear*; and in the past tense, amavi-sse, fui-sse. The old forms dicse (dicere), scripse (scripsisse), correspond closely to the Greek δεῖξαι (δεικ-σαι), γράψαι (γραπ-σαι), and all exhibit the same combination with *as*, to be. The same suffix is found in the Umbrian future perfect, *convortust* answering to the Latin *converterit*, *amprefus* (fus, fust = fuerit) to *ambiverit*, *ambrefurent* (furent = fuerint) to *ambiverint*, *fakurent* to *fecerunt*, *dikust* to *dicerit*, pointing to such forms as *fak-furent*, *dik-fust*, &c.

The ending of the Greek aorist imperative τύψαι, γράψαι, is probably the termination of the LOCATIVE CASE, this ending having belonged originally to the present as well as to the aorist, τύπτειν being referred to τυπτεμεναι, which, by dropping the case-ending, left τυπτεμεν, from which was obtained the contracted form τύπτειν.

In the tenses of modern languages the combinations are commonly more prominent; but their origin is not always obvious at first sight. Thus the future of obligation is in English formed by a combination with the verb *shall*; but *shall* (the Gothic skal), which looks like a present, is really an old perfect, answering to Greek perfects like οἶδα, which retain the force of the present. This *skal*, meaning *I am bound*, meant originally *I have killed*; and as, according to Teutonic law, the guilt of manslaughter could be atoned by a fine, the word meant strictly *I am guilty*, ich bin schuldig, and therefore 'I owe the fine for having slain a man;' and so the phrase 'he shall pay,' resolves itself into the expression 'he is guilty to pay.'

In the same way the auxiliary *may* was, in its primary signification, *I am strong* (akin to Greek μέγας, the Scotch *muckle*, Eng. *much*), and was likewise a preterite, from a root which meant *to beget*, whence the Scotch Mac, *a son*, and Gothic magaths, the English *maid*, a daughter.

Tension (Lat. tensio, *a stretching*). In Mechanics, the force by which a bar or string is stretched. Thus, when a weight is suspended by a string, the tension at every point of the latter is equal to that weight.

Tensor. [QUATERNIONS.]

Tensor Muscles. In Anatomy, those muscles which tighten the part to which they are fixed; as the tensor vaginæ femoris, tensor palati, &c.

Tent or **Tinta.** A Spanish red wine, chiefly from Malaga and Gallicia.

TENT. In Surgery, a plug of lint used for dilating wounds: a piece of sponge which has been imbued with wax is termed *sponge-tent*.

Tentacle (Low Lat. tentaculum, *a holder*). This term is used by Savigny in a restricted sense to signify the elongated, filiform, inarticulate appendages of the mouth of Annelides, but is also applied to all appendages, whether jointed or not, which are used as instruments of exploration and prehension. Thus, the oral arms of the Polyps, the prehensile processes of Cirripeds and Annelides, the cephalic feet of the Cephalopods, the barbs of fishes, are termed *tentacles*.

Tenth. A Musical interval, being the octave of the third.

Tenths. The tenth part of the yearly value of all benefices, which was anciently paid, with the first fruits, to the pope. [FIRST FRUITS.]

Tentorium. The process of the *dura mater* which separates the cerebrum from the cerebellum; it is occasionally, as in some carnivora, ossified, and forms a bony shelf.

Tenues (Lat. *thin*). The three letters *k*, *p*, *t* in the Greek alphabet are so called, in relation to their respective middle letters *g*, *b*, and *d*, and their aspirates *ch*, *ph*, and *th*.

Tenuirosters (Lat. tenuis, *slender*, and rostrum, *a beak*). The name of a tribe of Insessorial birds, including those which have a long and slender bill.

Tenure (from Lat. teneo, *I hold*). The feudal relation between lord and vassal in respect of lands. It is a fundamental maxim of the feudal system that all lands were, or at all events must be deemed to have been, originally granted out by the sovereign, and are therefore holden either mediately or immediately of the crown. The greater portion of the land in England was actually so granted out by William the Conqueror to his followers, and the same principle of tenure, or holding of the king, became established soon after the Norman Conquest, even with respect to those lands which remained in the hands of the original English holders. All the landowners in

the country thus became the vassals of the crown, and held their lands subject to the performance of certain duties or services as the condition of their enjoyment. The land holden was therefore styled a *tenement*; the possessors thereof, *tenants*; and the manner of their possession, a *tenure*. When such tenants as held immediately under the king granted out portions of their lands to inferior persons, they became also lords with respect to those inferior persons though they were still tenants with respect to the king, and were accordingly called *mesne* or middle lords. According to Blackstone, there were four principal species of lay tenures: 1. Tenure by knight service; 2. Tenure in free socage; 3. Tenure in pure villenage; and 4. Tenure in villein socage. The tenant by knight service was bound to attend his lord to the wars for forty days in every year if called upon (a duty afterwards commuted for an *escuage* or money payment), and his tenure was subject to the further burthens of *aids* or assistance to the lord in ransoming his person if captive, in making his eldest son a knight, and in providing a portion for his eldest daughter; *reliefs* and *primer seisin*, or fines paid to the lord upon the death of the tenant; *wardship*, or the right of the lord to the custody and profits of the land during the minority of the tenant; *marriage*, or the right of the lord to dispose of his ward in matrimony; *fines*, on occasions of alienation; and *escheat*, or forfeiture of the land to the lord, on failure of heirs of the tenant or corruption of his blood by felony. The lord's right of escheat, however, was subject to the paramount rights of the sovereign, to whom the lands of traitors were forfeited absolutely—those of felons for a year and a day; but forfeiture to the crown was rather a punishment for an offence than an incident of tenure. Tenure in *free socage* was free from the obligation of military service, though subject to the incidents of *escheat*, of attendance at the lord's court, and of giving customary aids, and in some cases to the payment of an annual rent, and of a *relief* of one year's rent. The only method, originally, by which the tenant could convey away part of his lands was by *subinfeudation*, or by making a grant to another person, reserving services corresponding with those due to the superior lord, thus creating a subsidiary tenure, and becoming himself a mesne lord; but as from the nature of some of the burdens or services incident to feudal tenure, it was an advantage to the lord that his lands should be in the possession of his own immediate tenants, the practice of subinfeudation was prohibited by the statute of Quia Emptores, 18 Edw. I., and other statutes which, while establishing the liberty of alienating lands held by free tenure, provided that the purchaser should hold them, not of the vendor, but immediately of the superior lord. Tenures in pure villenage and in villein socage are the origin of our present copyholds. The lord of a tract of land usually granted part of it to freemen, to be held in knight service or free socage, part he reserved as his own demesne, and part he granted to his villeins or serfs, to be held by villein tenure, subject to the performance of agricultural services or other servile works. These lands were originally held literally *at the will* of the lord, but the right of succession of heirs and of alienation, which was at first a mere indulgence, came by custom to be established as a right, while the servile part of the services became gradually obsolete as the condition of the copyholders improved.

Besides the lay tenures above mentioned, there remains a tenure of a spiritual nature, called tenure in *frankalmoign* or free alms, being that whereby religious corporations held their lands. This tenure is said to have existed before the Conquest, and was subject to none of the incidents of feudal tenure, tenants in frankalmoign being bound to perform only those religious or spiritual services as an endowment for which their lands were bestowed. It is by this tenure that the lands of the church are for the most part held at the present day.

With the decline of the feudal system, the obligations attending tenure by knight service gradually degenerated into a mere machinery for extorting money, and upon the restoration of Charles II. an Act of Parliament was passed (stat. 12 Ch. II. c. 24), by which tenure by knight service, aids, and other oppressive burdens, were abolished, and all tenures, except frankalmoign, copyholds, and the honorary services of grand serjeanty (a species of knight service), were turned into free and common socage. It is by free socage, then, that all fee simple lands in England are now held. Quit rents are still sometimes payable, though the change in the value of money has reduced them to insignificance, and land still escheats if the owner dies intestate and without heirs, or is attainted in consequence of murder; but in other respects the feudal incidents of socage tenure, never very burdensome, have been abolished or become obsolete. The doctrine of tenure, however, still forms an integral part of the law of England: it is impossible really to understand the simplest conveyance of land without referring to its principles, and most of the technical rules of real property law may be readily accounted for by remembering that, although they may now appear arbitrary and without significance, they once formed part of a great system under which all the landholders in the country were united, for purposes of public policy, in the closest bonds of mutual dependence and support.

The English tenures may be studied in Glanville, in Bracton, in Fleta, in Littleton, with Coke's *Commentary*, or in Blackstone. It is necessary, however, to say that much which is contained in these later writers was antiquated

at the time in which they wrote, though, as is customary with literary lawyers, they treated that which was theoretically existent as though it was in full operation. For instance, Coke treats of villenage as still holding good in his time, though the law courts had solemnly decided that the custom was obsolete. (Prof. Rogers, *Agriculture and Prices in the Middle Ages*.)

Tenures, Scottish. Scottish tenures were five in number, viz. 1. Military, or *ward holding*; abolished with all its *casualties* or incidents by 20 Geo. II. c. 50. 2. By *mortification* or *mortmain*; which now only applies to manses and glebes, retained by the Act of 1587 as mortified to the church. 3. *Burgage holding*, by which the burgesses of royal burghs hold lands and houses within the burgh of the sovereign by service of watching and warding, &c. 4. *Blanch tenures*, by which the grantee or vassal is bound to pay to the superior annually a species of quit-rent or acknowledgment. 5. *Feu-holding*, by grant, with reservation of pecuniary services. [Feu; Tenure.]

Tepal. Another name for *petal*. Also the pieces of a perianth, being of an ambiguous nature, between calyx and corolla.

Tepejilote. A Central American name for the flowers of a species of *Chamædorea*, which, while still enclosed in the spathes, are highly esteemed as a culinary vegetable.

Tephroite (Gr. τεφρός, *ash-grey*). A native silicate of manganese, found at Stirling, Sparta, and New Jersey, in crystalline and granular masses of an ash-grey colour, turning black on exposure.

Tephromantia (Gr. τέφρα, *ashes*, and μαντεία, *prophecy*). Divination from the figures assumed by red-hot embers.

Tephrosia (Gr. τεφρός, *ash-coloured*). A widely distributed genus of *Leguminosæ*, containing many species, growing for the most part in the tropical or subtropical regions of both hemispheres. The leaves are covered with a grey silky down, and the flowers are usually in terminal clusters, but occasionally stalked in the axils of the leaves. *T. apollinea*, a native of Egypt and Nubia, furnishes a kind of indigo. The seeds, moreover, are made into an ointment, used to heal the wounds of camels. The leaves and seed-vessels of this plant are occasionally found mixed with Alexandrian senna. *T. cinerea* is employed in the West Indies to stupefy fish. The leaves and stems of *T. toxicaria* are used for the same purpose in the West Indies, the Feejee Islands, and elsewhere. The stems and leaves are pounded and thrown into a river or pond, when the fish speedily become stupefied; the larger fish are stated to recover if placed in fresh water, but the smaller ones perish. The roots of this plant are employed as an application in certain skin-diseases in the Mauritius, Surinam, &c.

T. purpurea is used medicinally in various ways by the natives of India. Thus, the roots, pounded and mixed with arrack, are used as a wash for the mouth, and in the form of ointment are applied in cases of elephantiasis, while the juice of the plant is used, mixed with honey, as an application to pustular eruptions on the face.

Tequesquite. A native crystallised carbonate of soda, which is found in several lakes in Mexico, and is used in the smelting of silver-ore.

Teraphim. A word used thirteen or fourteen times in the Old Testament, and commonly rendered by our translators *idols*. Bryant explains them as 'lunar amulets, or types of the ark in the form of crescents, supposed to have been invented by the patriarch Terah.' They were also consulted by the ancient Jews for oracular answers. (*Antiq*. iii. 321.) In later times, strange and horrible practices of witchcraft are described by Rabbinical writers in explaining this word. The teraph, according to Rabbi Eliezer, was made by killing a first-born child, opening the head, putting a gold plate with the name of the impure spirit under the tongue, &c. (See also the notes to Southey's *Thalaba*, book i.)

Teratolite (Gr. τέρας, *a sign*; λίθος, *stone*). A hydrated silicate of alumina, peroxide of iron, lime, magnesia, &c. from the coal formation of Planitz in Saxony. It is the *Terra miraculosa Saxoniæ*, which was formerly supposed to possess valuable medicinal properties.

Teratology (Gr. τερατολογία). That branch of physiological science which treats of the various malformations and monstrosities of the organic kingdoms of nature.

Terce Major. In Card-playing, a sequence of the three best cards.

Terebellum (Lat. terebro, *I bore*). The name of a genus of buccinoid pectinibranchiate Gasteropods, having an oblong shell with a narrow aperture, destitute of folds and ridges, and gradually enlarging to the extremity opposite to the spire.

Tereben. The liquid product obtained after the purification of oil of turpentine by sulphuric acid.

Terebinth-tree. [Pistacia.]

Terebinthaceæ (Gr. τερέβινθος). An order of polypetalous Dicotyledons established by Jussieu, and adopted by all botanists who unite *Anacardiaceæ* with *Burseraceæ*; but as these are now definitively separated, Jussieu's name has been abandoned.

Terebrantia (Lat. part. of terebro, *I bore*). The name of a section of Hymenopterous insects, characterised by the possession of an anal instrument organised for the perforation of the bodies of animals, or the substance of plants. The borer (*terebra*) is peculiar to the female, and is composed of three long and slender pieces, of which two serve as a sheath for the third; it is placed at the anal extremity of the abdomen, and the oviduct is continued into it. The females instinctively use this weapon to prepare a place for the deposition of their eggs, where the maggot may be incubated in safety and upon its exclusion be surrounded by already organised matter adapted

for its sustenance. Some genera select vegetables for the parasitic support of their young, as *Sirex* (Linn.), which infests the pine-tree; and *Cephus* (Latr.), which perforates the stalks of corn for the purpose of oviposition. Others, as the ichneumons, pierce the skins of insects, and deposit their eggs in the subcutaneous fatty and nutrient material. Some ichneumons are provided with long and extensible anal borers, which they insinuate beneath the bark of trees, and into crevices and fissures, where their instinct and peculiar antennal organs of sensation enable them to find the insect which may form a fitting nidus for the parasitic and carnivorous larvæ. Other ichneumons, with short terebræ, place their ova in the bodies of Lepidopterous larvæ, or in those pupæ which are readily accessible to their attacks.

The female ichneumons manifest a wonderful instinct at the season of oviposition in discovering the insects, as well mature as in their different stages of egg, maggot, caterpillar, and chrysalis, which are obnoxious to the wounds of the instrument from which the present section of *Hymenoptera* takes its name.

Terebratula (Lat. terebro). The name of a genus of palliobranchiate acephalous bivalve Molluscs, in which one of the valves is perforated for the transmission of a peduncle. The hole through which the peduncle passes is completed by a small detached calcareous piece.

Teredo (Lat.; Gr. τερηδών, *the ship-worm*). The name of a genus of acephalous Molluscs, which bore their habitations in submerged timber, and cause great mischief in sunken piles, ships' bottoms, &c. [BORING WORM.]

Terenite (Gr. τέρην, *tender*). A kind of altered Scapolite.

Tereus. In Greek Mythology, a king of the Thracians, or Highlanders, in Daulis, and husband of Procne, by whom he became the father of Itys. Hiding Procne away, he married her sister Philomela, cutting out her tongue. But Philomela found Procne, who killed her son Itys, and (like Tantalos) placed his flesh before Tereus, and then fled from his pursuit. According to some versions, all three were changed into birds; while others related that the sisters wept themselves to death in Attica.

Tergum (Lat. *the back*). In Entomology, this term signifies the upper or supine surface of the abdomen.

Term (Lat. terminus, Gr. τέρμα, *a boundary*). In Logic, the expression in language of the notion obtained in an act of APPREHENSION. A term may consist of one word, or of several; but every word is not capable of being employed by itself as a term; i.e. in logical language, *categorematic*. Adverbs, prepositions, &c., and also nouns in any other case besides the nominative, are syncategorematic, i. e. can only form part of a term; while a verb is a mixed word, being resolvable into the *copula* (or auxiliary verb) and the *term*, to which the copula gives *tense*, *mood*, and *position*; but an infinitive mood is a term by itself. Simple terms, or categorematics, are divided into *singular* and *common*. A singular term stands for one individual; as 'Cæsar,' 'the king.' It is obvious that these terms cannot be affirmed or denied (in logical phrase, predicated affirmatively or negatively) of anything but themselves. A common term stands for many individuals (which are called its significates), as 'man,' 'king.' These, it is evident, can be said (or predicated) of others; e.g. 'Cæsar is a man,' 'Frederick is a king.' The subject of a proposition, therefore, may be either a singular or a common term; the predicate must be a common term. Terms are said to be *univocal*, *equivocal*, *analogous*, &c.; but these are rather distinctions of language than of logic. They are also said to be 'of the first intention,' and 'of the second intention;' the first appearing to be words used in a vague and general sense; the latter, words used in a limited and specific sense, which they bear in some particular art or science. [PROPOSITION.]

TERM. On Shipboard, the name applied to the carved work under each end of the taffrail.

Term of Years. In Law, the term for which a lease is granted, or the interest acquired by the lessee. By a curious anomaly in our law, a term of years, although it may give the absolute right to the possession and enjoyment of real estate for a thousand years or more, is considered to be personal and not real property, and devolves accordingly, upon the death of its owner, to his executors or administrators, and not to his heir. For terms of years were anciently created for farming purposes alone, and a farmer of land was in early times regarded more as the bailiff of the landowner than as a person having an independent property of his own. His interest, such as it was, had nothing military or feudal about it, and was consequently exempt from the feudal rule of descent to the eldest son as heir-at-law. (Williams *On Real Property*.) Terms of years, at the present day, are created for many purposes, and long terms are often made use of in settlements, wills, &c. as convenient means of securing the payment of money. [SATISFIED TERM.]

Terms. In Algebra, the parts of any expression which are separated from each other by the signs + and − are usually called *terms*. The constituents of a term are called its *factors*, and the term itself is said to be *compound* if one of its factors itself consists of two or more terms. Thus, $ab^2 + (b-c)\,d^2 - a\,b\,c$ might be called an expression of three terms, each containing three factors; the second would then be called a compound term, since one of its factors $(b-c)$ consists of two terms.

TERMS. In Law, terms are four sections of the year appropriated to the transaction of particular business in the superior courts of common law and equity. They are now regulated by 11 Geo. IV. and 1 Wm. IV. c. 70.

Hilary Term begins the 11th, and ends the 31st of January.

Easter Term begins 15th of April, and ends the 8th of May.

Trinity Term begins 22nd of May, and ends the 12th of June.

Michaelmas Term begins the 2nd, and ends the 25th of November.

Whenever any one of these days falls on a Sunday, the following Monday is substituted for it; and if the days from Thursday before to Wednesday after Easter Sunday inclusive, or any part of them, fall within Easter term, such days are regarded as holydays, and the term is increased by an additional number of days at the end, and Trinity term proportionably postponed. During term, the three superior common law courts sit in banc; and all their business, with the exception of the trial of issues of fact, and matters of minor importance, transacted before a judge at chambers, was formerly then performed. The power of the courts has, however, been increased by recent statutes enabling them to transact term business in vacation time, which includes all the year, except the terms. During the vacation, also, the circuits are held, in which causes are tried and the gaols delivered. The Court of Chancery transacts its ordinary business in vacation as well as in term time, its sittings being regulated by the Lord Chancellor.

Terminal Velocity. The uniform velocity which a body obtains when, after falling through the atmosphere, the resistance of the air has become equal to the accelerating force of gravity.

Terminalia (Lat. terminalis, from terminus, *an end*). In Botany, a group of trees or shrubs, dispersed over the tropics of both hemispheres. The astringent fruits of several of them have long been employed for tanning and dyeing purposes by the natives of India; and are now brought to this country in considerable quantities, under the name of Myrobalans, and used chiefly by calico printers for the production of a permanent black. The principal kinds of Myrobalan are the Chebullic, the produce of *T. Chebula*, which are smooth and oval; and the Belleric, *T. Bellerica*, obscurely five-angled, and covered with greyish silky down. The seeds of *T. Catappa* are like almonds in shape and whiteness, but though palatable they have none of their peculiar flavour.

TERMINALIA. Annual festivals celebrated by the Romans in the month of February, in honour of Terminus, the god of boundaries. [TERMINUS.]

Terminists. In Ecclesiastical History, a name given to a class among the Calvinists whose tenet it is (or was, for such opinions hardly exist at the present day) that there are persons to whom God has fixed, by a secret decree, a certain *term* before their death, after which He no longer wills their salvation however long they may live. They instanced the cases of Pharaoh, Saul, and Judas, among others.

Terminology (a word coined from Lat. terminus, and Gr. λόγος). In every science or art, the definition of the words and phrases peculiarly employed in it (in other words, its *technical terms*) is called its *terminology*.

Terminus (Lat.). A Roman deity who presided over boundaries and frontiers. This god appears to have been Jupiter himself, regarded as the protector of boundaries (Ζεὺς ὅριος). The limits consecrated to him were not to be transgressed, and every year sacrifices, called *terminalia*, were there to be offered up, in order to keep them inviolate. The circumstance that no terminus was allowed to be under cover, and that a terminus existed on the Capitol, is a further proof of the identity of this deity with Jupiter or ZEUS.

TERMINUS. [STATIONS, RAILWAY.]

Termites (Lat. termes, *a bough* or *twig*). These insects constitute an extensive and important tribe of the Neuropterous order, confined to the warmer latitudes of the globe, and taking an important part in the comminution and destruction of dead and decomposing organised matter. The termites are all social, terrestrial; and are active, carnivorous or omnivorous, in all the stages of their existence, save that of the ovum, after which they undergo only a semi-metamorphosis. The mandibles are always strong and hard, but differ in relative size in different classes of individuals of the same community.

The tribe *Termitinæ* includes the genera *Mantispa*, *Raphidia*, *Psocus*, *Perla*, and *Termes* proper (now the type also of a family, *Termitidæ*, or white ants, as they are commonly called). These are characterised by four-jointed tarsi: but the wings are carried horizontally on the body, and are very long: the head rounded, and the prothorax short and square. The body is depressed, with the antennæ short; the mouth very similar to that of the *Orthoptera*, with the four-cleft lower lip: three ocelli, one rather indistinct; the wings generally but slightly transparent, coloured, with the nervures not forming a close network; and the legs short.

The termites peculiar to the tropical and adjacent countries are known under the name of *white ants*, and commit great ravages, especially in the larva state, in which they are called *workers*; these are like the perfect insect, but with the body softer, and without wings, and the head generally larger and destitute of eyes, or nearly so. They are united into colonies of incalculable numbers, and live concealed in the interior of the earth, trees, and other wooden matters, such as furniture, shelves, &c. in which they make galleries, forming routes conducting to the centre of their nests; so that these objects, of which the outer surface is (with surprising instinct) left uninjured, fall to pieces on the slightest touch. The nests of some species are external, but without any visible exit. Sometimes they are raised to a great height above the surface, like pyramids, occasionally surmounted by a solid roof, which, by their height and number, appear at a distance like a small village. Sometimes these insects affix their nests to the branches of

trees. Another kind, termed *neuters* or *soldiers*, and which Fabricius mistook for pupæ, defend the nest. These have a head much larger and longer; and the mandibles are very long, and cross over each other. They are far less numerous than the larvæ, and live near the outer surface of the nest, so that they make their appearance just when it is attacked: they are also said to compel the workers to labour. The demi-nymphs have the rudiments of wings, and in other respects resemble the larvæ.

When arrived at the perfect state, the termites quit their habitation, flying abroad during the evening and night in great numbers. Before morning, they lose their wings, and, falling to the earth, become the prey of birds, lizards, &c. Latreille conjectures that the act of coupling takes place in the air, as in the ants, and that the females alone occupy the attention of the larvæ for the establishment of fresh colonies. The abdomen of the female subsequently acquires an enormous size, from the innumerable eggs which it contains. The royal chamber occupies the centre of the habitation, and around it are distributed those which contain the eggs and provisions.

Some larvæ of *Termes varium* have eyes, and appear to have habits somewhat different to the rest, and to approach our ants.

Negroes and Hottentots are very fond of these insects.

Ternate (Lat. ternus, *three*, distributive). In Botany, a term applied when three things are in opposition round a common axis: a whorl of three.

Ternströmiaceæ (Ternströmia, one of the genera). An order of hypogynous polypetalous Exogens, consisting of trees or shrubs, chiefly tropical, many of them of great beauty, which, like the *Clusiaceæ* (*Guttiferæ*), have imbricated sepals and petals, indefinite hypogynous stamens, and a free ovary divided into cells with the placentas in the axis; but they differ from that order generally in their alternate leaves, hermaphrodite flowers, and usually curved embryo, much less fleshy, and often enveloped in albumen. These characters have, however, several exceptions, and the precise distinction between *Ternströmiaceæ* and *Clusiaceæ* is not easily traced.

Terpsichore (Gr.). In the Hesiodic *Theogony*, one of the nine MUSES, supposed in later times to preside especially over choral song and dancing.

Terra Cotta (Ital.; Lat. terra cocta, *baked clay*). The name given to statues, architectural decorations, figures, vases, &c. modelled or cast in a paste made of pipe or potter's clay and a fine-grained colourless sand, with pulverised potsherds, slowly dried in the air, and afterwards fired to a stony hardness in a proper kiln. [BISCUIT.]

Terra Japonica. The old Pharmaceutical designation of the substance now called CATECHU. It was formerly regarded as an earthy mineral.

Terra Ponderosa (Lat.). The old Mineralogical name of carbonate and sulphate of baryta. [BARYTES.]

Terra di Sienna (Ital.). A kind of Ochre of a brownish-yellow colour found near Sienna in Italy. It is used as a paint both in its natural state (*raw Sienna*); and after ignition, when it becomes of a rich chestnut colour, and is called *burnt Sienna*.

Terrace (Fr. terrasse). In Architecture, a raised natural or artificial bank for the purpose of affording a promenade.

Terræ Filius (Lat.). In Classical Latinity, a humorous designation of persons of low origin or obscure birth: terræ filii, *sons of the earth*. (Persius, *Satire* 6.) In the university of Oxford, by an ancient custom, abolished a century ago, a satirical Latin oration was read at the commemoration annually by an undergraduate, who assumed the title of Terræ Filius. [AUTOCHTHONS.]

Terre-plein (Fr.). In Fortification, the upper surface of the rampart where the guns are placed and worked. Its breadth should be about forty feet; and it is bounded outside by the parapet, and inside by the inner slope of the rampart. [FORTIFICATION.]

Terre-verte (Fr.). Green-earth. A species of Chlorite of a green or olive colour, found in Germany, France, Italy, and North America. The green-earth of Verona, formerly used as a pigment, is a variety of this mineral. [CHLORITE.]

Terrestrials (Lat. terrestris, *the earth*). The name of a section of the class *Aves*, corresponding to the orders *Rasores* and *Cursores*; also of a family of Pulmonated Gastropods, and of a division of Isopodous Crustaceans.

Terrier (Low Lat. terrarium, from terra, *the earth*). In Feudal Law, a description or enumeration of the various lands and tenements held in a manor, with the extent of the lands, the names of the tenants, and the rents or services due from each. The most ancient, valuable, and extensive terrier is that of Domesday. These terriers were often reviewed or acknowledged by the homage of the manor, and, forming as they did important evidence as to title, were preserved as the most valuable among national, royal, or private muniments. They are very important to antiquaries, as supplying much information on the distribution of land, and the social habits of the community.

The term is now usually applied only to *ecclesiastical* terriers, or catalogues of the lands and other temporal possessions of the church in each parish, directed by the 87th canon to be kept in the Bishop's Registry.

TERRIER. This name also denotes a small variety of dog, used for drawing foxes when they take to earth on being hunted.

Terror, Reign of. In the History of the French Revolution, this term has been generally applied to the period during which the executions were most numerous, and the country under the sway of the terror inspired by the ferocious measures of its governors, who had

established it avowedly as the principle of their authority. It seems to be most properly confined to the period between October 1793 (when the revolutionary tribunal, although constituted at an earlier time, was first put in permanent action on the fall of the party of the Gironde) and the overthrow of Robespierre and his accomplices in Thermidor (July) 1794. The agents and partisans of the system have been termed *Terrorists*.

Tertials (Lat. tertius, *third*). Tertials are the large feathers which take their rise from the proximate extremity of the bones of the wing, corresponding to those of the forearm near the elbow joint, forming a continuation of the secondaries. They are so long in some birds, of the snipe and lapwing kind, that when the bird is flying they give it the appearance of having four wings.

Tertian Fever. An intermittent fever or ague, the paroxysms of which return every other day. [AGUE.]

Tertiaries. In Ecclesiastical History, associates of the Franciscans, who acknowledged the *third* rule of Saint Francis, and seem connected with the Fraticelli and Beghardi of the thirteenth century.

Tertiary or **Cænozoic.** The uppermost of the three great natural divisions of stratified fossiliferous rocks. The term *tertiary* has reference to the original grouping of such rocks. The term *primary*, originally intended to include the older group (supposed to be non-fossiliferous), was afterwards found too inclusive and to involve a theory since abandoned, and is now no longer used. The fossiliferous members of the older series are now known as *palæozoic*; the term *secondary* includes the principal fossiliferous series developed in England; and the *tertiaries*, which are poorly developed in our island, are recognised as a third great natural division, although they were at one time regarded as modern and comparatively unimportant.

A very large proportion of the earth's surface is covered with rocks of this newest of the three geological periods, and it is now understood to admit of many great and important subdivisions. Some notice of the most remarkable of these will be found under the various headings referred to in the article DESCRIPTIVE GEOLOGY.

Tertiary rocks were originally thought to occupy basins, and to be, to a great extent, of freshwater origin. It is true that the deposits of this newer period are, in Europe, more broken and detached than the secondary rocks; but this is due to the fact that at the time of their deposit large tracts of land were coming into existence in this part of the northern hemisphere. Elsewhere, as in South America, the tertiary rocks are continuous deposits, fully equal in all dimensions to the largest secondary or palæozoic rocks of any one period, and a large proportion are marine.

Tertiary rocks are rich in fossils, and the organic remains yielded by them have naturally a greater resemblance to familiar modern species now living, than that which is seen in those of the secondary and palæozoic rocks.

It has long been known that vast deposits of lignite occur in tertiary rocks, corresponding in some measure with the deposits of coal of the palæozoic period, but greatly inferior in value. It is now known that true coal of excellent quality occurs in Hungary in large basins of the middle tertiary period.

Such of the metals as occur in veins in metamorphic rocks are generally less abundant in tertiary rocks, owing to the fact that those now at the surface have not yet undergone full metamorphosis. On the other hand, certain metals, such as gold, removed by abrasion or weathering from veins, and collected with sands or gravels, are almost entirely confined to these more modern deposits. Tin is also not unfrequently found in stream works.

The tertiary rocks pass by insensible gradations into those of modern date and recent formation. There is no abrupt change of any kind common to all parts of the world, either in reference to the tertiaries or other rocks.

The following tabular view of the tertiary and modern deposits in some detail will be useful for reference, as it shows the present state of knowledge on the subject:—

British.	*Foreign.*
RECENT.	
Marine deposits with human remains in Cornwall and in the Clyde estuary. Kitchen middens in Scotland. Lake dwellings of Ireland.	Kitchen middens of Denmark with bronze and stone weapons, &c. Lake dwellings of Switzerland. Marine deposits of Bay of Naples. Lake deposits of Cashmere.
INTERMEDIATE. (*Glacial.*)	
Cavern deposits, Brixham, &c. River valley alluvia of Ouse and Thames. Glacial drift, Scotland. Boulder clays, Norfolk. Elephant beds, Norfolk. Moel Tryfaen drift, with marine fossil shells, 1,400 feet above the sea.	Amiens gravels with sculptured flints. Liége cavern deposits. Dordogne cavern deposits. Gibraltar cavern deposits. Malta cavern deposits. Australian cave breccias. Rhine Loess. Old Nile mud in terraces. Sardinian marine strata. Glacial drift of Northern Europe. North American mastodon deposits.

N.B.—All these probably, most of them certainly, contain remains of human tribes inhabiting the country at the time of the deposit.

NEWEST TERTIARY. (*Newer Pliocene.*)	
Norwich clay with mastodon. Chillesford beds (Arctic shells). Bridlington beds (do.).	Tufaceous (marine) deposits in Ischia, Monte Somma, and skirts of Etna. Volcanic tuff (fresh-water) of Sicily. Deposits of Upper Val d'Arno.

(*Older Pliocene.*)

Suffolk (red) crag.	Antwerp crag.
Coralline crag.	Sub-apennine deposits.
	Aralo-caspian deposits.

MIDDLE TERTIARY.

(*Upper Miocene.*)

Sands over North Downs (?).	Antwerp (Edeghem) beds.
	Diest sands, Belgium.
	Faluns of Loire and Bordeaux.
	Eppelsheim sands.
	Vienna deposits (Dinotherium).
	Turin (Superga) beds.
	Greek deposits near Athens with fossil monkeys.
	Oeningen beds (Swiss) plants and insects.
	Madeira, Canaries, and Azores volcanic tuff, and limestone.
	Swiss molasse (marine).
	Siwalik deposits.
	North American (Atlantic coast) marine deposits.

MIDDLE TERTIARY.

(*Lower Miocene.*)

Hempstead beds, Isle of Wight.	Fontainebleau sands.
Bovey Tracey lignites.	Auvergne lacustrine deposits.
Isle of Mull leaf-bed.	Lower Bordeaux faluns.
	Mayence basin.
	North German lignites.
	Lower molasse (Switzerland).
	Middle and lower Limburg beds (Belgium).
	Nebraska beds.

LOWER TERTIARY.

(*Upper Eocene.*)

Isle of Wight beds, Bembridge, and St. Helens.	Montmartre gypsums.
Headon series and Barton clay.	Calcaire siliceux.
	Grès de Beauchamp.

(*Middle Eocene.*)

Bagshot and Bracklesham beds.	Calcaire grossier.
Alum Bay white clays.	Miliolite limestone.
	Nummulite beds of the Soissonnais.
	Claiborne beds (U.S.).

(*Lower Eocene.*)

London clay.	Dunkerque London clay.
Woolwich beds of plastic clay.	Plastic clay of France.
Thanet sands.	Bracheux sands.
	Nummulite formation of India.
	Flysch.

Tertium Sal (Lat.). An obsolete chemical term formerly applied to neutral salts, as being a third substance, resulting from the union of an acid and alkali.

Tertullianists. In Ecclesiastical History, a branch of the African Montanists; so named from Tertullian, who embraced Montanist opinions.

Teruncius (Lat.). A coin of ancient Rome, the same as the *quadrans* or *triuncis*, being the fourth part of the *as*, and consequently containing three ounces before the value was diminished.

Terza Rima (Ital. *third* or *triple rhyme*). A peculiar and complicated system of versification, borrowed by the early Italian poets from the Troubadours. The verses are the ordinary Italian heroic lines of eleven syllables (interspersed very rarely with ten-syllable lines). The rhyme is thus arranged: At the commencement of a poem or portion of a poem, verses 1 and 3 rhyme together, as do verses 2, 4, and 6; the third rhyme begins with verse 5, which rhymes to 7 and 9; the fourth is formed by 8, 10, and 12, and so on; and the poem or canto ends abruptly—the last rhyme, like the first, being on a couplet instead of a triplet. It is obvious that the rhyme is interlaced throughout, and continually in suspense, so that no pause can be found until the end of the poem or canto; as, at the end of every line, there must still be a rhyme incomplete. This continuity gives a very peculiar character to the metre, and renders it highly expressive of sustained narrative or passion, and the abruptness of the conclusion is often turned to good effect by masters of versification. This metre has been rendered celebrated by Dante, who wrote in it his *Divina Commedia*. It has been adopted by his imitators, of whom the latest, Vincenzo Monti, has used it to much advantage; and by Ariosto and other poets for their satires. Byron has adopted it in English, in his *Prophecy of Dante*; and it has been attempted by various translators.

Terzetto (Ital.). In Music, a composition in three parts.

Tesselated Pavement (Lat. tessella, dim. of tessera). In Ancient Architecture, a pavement formed of small square pieces of stone called *tesseræ*. They are frequently, indeed mostly, found inlaid in different colours and patterns, and with a central subject. They are embedded in cement, and rest on prepared hard strata.

Tesselite. A cube-like variety of Apophyllite of a peculiar tesselated or mosaic-like structure, from Talisker in Skye, and Naalsoe in the Faroe Islands.

Tessera (Lat.). In Architecture. [TESSELATED PAVEMENT.]

TESSERA. In Roman Antiquities, a die six-sided, like the modern dice; and thus to be distinguished from the talus, which had only three sides. Tickets or tallies used for various purposes were called *tesseræ*. Thus, guards were set at night in their camps by means of a tessera with a particular inscription, given from one centurion to another through the army; and in this way the word *tessera* seems to have come to signify the watchword or password delivered to the guard. (*Mém. de l'Acad. des Inscr.* vol. xxxvii.)

Tesseraconteris (Gr. τεσσερακοντήρης). A galley with forty banks of oars; one of the largest of monstrous vessels mentioned by ancient writers. Great doubts have been entertained as to the possibility of the construction of a vessel which, according to the received notions respecting ancient shipbuilding, must

have required about *four thousand* rowers; but it is seriously recorded that one was built for Ptolemy Philopater, probably for purposes of show only. [GALLEY; TRIREME.]

Tessular. A term applied in Crystallography to a system of crystals, including the cube, tetrahedron, &c.

Test (Lat. testis, *a witness*). In Chemistry, anything by which chemical substances are distinguished from each other: thus, infusion of galls is a *test* of the presence of iron, which it renders evident by the production of a black colour in water and other liquids containing that metal. In the same way sulphuretted hydrogen is a test of the presence of lead, and nitrate of baryta of sulphuric acid. In Metallurgy and Assaying, the porous crucible which absorbs the liquid vitrifiable oxide of lead and other metals combined with it is sometimes called the *test*.

Test and Corporation Acts. The popular names of the statutes 13 Ch. II. st. 2 c. 1, and 25 Ch. II. c. 2; by the first of which it was provided that all magistrates in corporations should take the oaths of allegiance and supremacy, and another oath renouncing the doctrine that it is lawful to take arms against the king; and should have received the sacrament according to the rites of the church of England within a year before their election. The latter statute extended these provisions to 'all persons that shall bear any office or offices, civil or military,' &c.; and introduced a new declaration against transubstantiation. These Acts, long esteemed the great bulwarks of the Protestant church, were nevertheless evaded by means of Acts of indemnity annually passed for the relief of those who had neglected to take the oaths. They were finally repealed in 1828 (9 Geo. IV. c. 17), as far as regarded the administration of the sacrament. A declaration was substituted, which was abolished in 1866. Locke, as well as many other eminent men, strongly objected to the principle of making a religious solemnity a test of citizenship; it was defended by Dean Swift.

Testa (Lat.). In Botany, the integuments of a seed.

Testa di Quaglia. The Italian name for *Martynia proboscidea*.

Testaceans (Lat. testa, *a shell*). This term was employed by Linnæus to signify an order of the class *Vermes*. It is applied by Cuvier to an order of his class *Acephala*, comprehending those which are provided with a calcareous shell.

Testacellus (Lat. testa). A genus of slugs; so called from their being furnished with a diminutive shell, which forms a shield or protection to the heart. Of this destructive genus the following species are British, and occasionally infest our gardens and nursery grounds: *Test. scutellum*, Sowerby; *Test. haliotideus*; *Test. Maugei*.

Testament. In Law. [WILL.]

Testament, Old and New. [BIBLE.]

Testator (Lat.). One who makes a will.

Testimony. [EVIDENCE; HISTORICAL CREDIBILITY.]

Testing. In Metallurgy, the operation of refining gold and silver by means of lead upon a vessel called a *test* or cupel. [CUPELLATION.]

Testudinaria (Lat. testudo, *a tortoise*). A genus of *Dioscoreaceæ*, remarkable for the rootstock or rhizome being wholly above ground, and coated with a bark-like corky or woody substance, which in time becomes deeply cracked and forms large angular protuberances, which may be compared to the shell of a tortoise; hence its generic name. These rootstocks are usually more or less globular, and frequently of a large size, some of them measuring four feet in diameter. Several slender climbing stems rise from their summit, and grow to the length of thirty or forty feet; these bear small entire more or less heart-shaped leaves, in the axils of which the short racemes of little inconspicuous greenish yellow flowers are produced. The species are natives of the Cape of Good Hope; the best known, *T. elephantipes*, is occasionally seen in greenhouses in this country, where it is commonly called the *elephant's foot*, in reference to its unwieldy rootstock. At the Cape it is known as Hottentot's Bread, the fleshy inside of its rootstocks having at one time afforded part of the food of the Hottentots, though now only eaten by baboons and other brute animals.

Testudinata (Lat. from testudo, *a tortoise shell*). The name of a tribe of Chelonian reptiles, of which the tortoise (*Testudo*) is the type. It has been sometimes used as synonymous with *Chelonia*, and as a name for the whole order.

Testudo (Lat.). A military contrivance adopted by the Greeks and Romans principally in attacking walls and fortified places. It was formed by a body of troops holding their shields above their heads, so as to overlap one another and form a kind of penthouse, which threw off the missiles of the enemy while the assailants were approaching the walls. The word properly means a tortoise, from the similitude of its shell to this contrivance.

Tetanus (Gr. τέτανος, *a straining*). A spasm of the whole of the muscles. It is frequently caused by lacerated wounds, and when it affects the jaw it is termed *lock-jaw.*. Spasms of the muscles of the jaw may, however, occur quite independently of tetanus or general spasm. Such cases are designated TRISMUS. In hot climates tetanus is sometimes produced by exposure to cold, or by suppressed perspiration, and it then sometimes admits of relief and cure; but when it is the consequence of a wound, it is usually fatal. In poisoning by strychnia, spasms of a tetanic character are observed.

Tetartin (Gr. τέταρτος, *fourth*). A name for Albite.

Tête du Pont (Fr. *head of a bridge*). In Fortification, a field work, generally open at the gorge, resting its flanks on the banks of a river, in order to cover one or more bridges.

Tethydans. The name of a tribe of Tunicated Acephalous Molluscs, of which the genus *Ascidia* (*Tethys* of the ancients) is the type.

Tethys (Gr. τῆθος, *an oyster*). A name applied by Linnæus to a genus of *Vermes Testacea*; and by Cuvier to a genus of Nudibranchiate Gastropods, characterised by having two rows of branchiæ along the back in the form of tufts.

TETHYS (Gr. Τηθύς). In the Hesiodic *Theogony*, a daughter of Ouranos (*heaven*), and Gaia (*earth*), and a sister of HYPERION, and Rhea, who intrusted her with the charge of HERA.

Tetracera (Gr. τετράκερος, *four-horned*). A genus of *Dilleniaceæ* consisting mostly of climbing shrubs, widely spread over the tropics of Asia, Africa, and America. The species have some astringent qualities. *T. potatori* is called the Water-tree at Sierra Leone, because its climbing stems yield a good supply of clear water when cut across. In Brazil a decoction of *T. Breyniana* and *T. oblongata* is applied to swellings of the legs, prevalent in that country; while in Guiana an infusion of the Tigarea (*T. Tigarea*, called *Liane rouge* by the French in Cayenne, from the red colour of its infusion) is employed in venereal complaints.

Tetraceros. The generic name proposed by Dr. Leach for the four-horned antelope.

Tetradites. A word used in several senses, all of them, however, bearing upon its original derivation from Gr. τέτταρες, *four*. 1. Among the ancients, children were so called who were born on the fourth day of the month; and such were believed to be unlucky. 2. The Manichees and others, who believed the Godhead to consist of four instead of three Persons, bore this name. And, 3. In Ecclesiastical History, different sects of heretics were so called, from the respect with which they regarded the number four.

Tetradrachm (Gr. τετράδραχμος). A common silver coin of the ancient Greeks, of the value of four drachms.

Tetradymite (Gr. τετράδυμος, *fourfold*, from its occurrence in quadruple crystals). A native sulpho-telluride of bismuth, generally found massive with a foliated structure, but sometimes in tabular crystals of a pale lead-grey colour, and with a metallic lustre, in the quartz rock of Brandy Gill in Cumberland; also in Hungary, &c.

Tetradynamous (Gr. δύναμις, *power*). In Botany, this term is applied to flowers which have six stamens, of which two are short, and separated by two pairs of longer ones.

Tetraeteris (Gr.). In Grecian Chronology, a cycle of four years, invented by Solon, to make the lunar year equal to the solar. This he effected by intercalating a month of twenty-two days at the end of two years, and at the lapse of other two years another month of twenty-three days, making in all forty-five days, which will be found to be the difference between the lunar and solar year after an interval of four years.

Tetragon (Gr. τετράγωνος, *four-angled*). A figure of four angles or corners. [QUADRANGLE.]

Tetragoniaceæ (Tetragonia, one of the genera). A small order of perigynous Exogens, sometimes united with *Portulacaceæ*, but differing from them essentially in their several-celled ovary. They are much more closely connected with *Mesembryaceæ*, and are often united with them as a sub-order, only differing in the usual absence of petals. They are succulent-leaved herbaceous plants, chiefly maritime, and are found generally within the tropics, in the South Sea Islands, in Southern Africa, and in the Mediterranean region.

The genus *Tetragonia* consists of herbaceous plants with four-cornered fruit, and one of the species, native of New Zealand, is cultivated as an esculent under the name of *New Zealand spinach*. This, although altogether inferior to genuine spinach, is valuable on account of its resistance to drought, and the great quantity of foliage that may be gathered from a single plant. It is an annual, of the easiest culture.

Tetragram (Gr. τετράγραμμος, *with four lines*). A figure formed by four right lines. [QUADRILATERAL.]

Tetragrammaton (Gr.). Among several ancient nations, the name of the mystic number four, which was often symbolised to represent the Deity, whose name was expressed in Hebrew by four letters, יהוה.

Tetragynia (Gr. τέτρα, and γυνή). In Botany, one of the orders of the Linnæan classification, comprising plants with four pistils.

Tetrahedral Co-ordinates. [CO-ORDINATES.]

Tetrahedrite. A native sulphide of copper of very complex composition; containing variable proportions of antimony, of arsenic [TENNANTITE], or of both antimony and arsenic (Grey Copper-ore), and sometimes of silver, or of mercury.

It is found both crystallised and massive in various Cornish mines, at Combe Martin in Devonshire, in Scotland, Ireland, Hungary Saxony, Transylvania, &c. The name has reference to the tetrahedral form of the crystals in which it usually occurs.

Tetrahedron (Gr. τέτρα, and ἕδρα, *side*). A solid bounded by four planes. It has also four corners or angles, and six edges. The regular tetrahedron is one of the platonic bodies. [POLYHEDRON.]

Tetrahedron, Fundamental, or **Tetrahedron of Reference.** [CO-ORDINATES.]

Tetralogy (Gr. τετραλογία). The name given to the collection of four dramatic compositions brought forward for exhibition at Athens by competitors for scenic honour. It consisted of three tragedies and a satyric drama. [SATIRE; TRILOGY.]

Tetrameter (Gr. τετράμετρος). A verse consisting of four measures; i.e. according to the Greek prosody, of eight iambic, trochaic, or anapæstic feet.

Tetrandria (Gr. τέτρα, and ἀνήρ). In Botany, the fourth class of the Linnæan system of classification, containing plants furnished with four stamens.

Tetrandrous. In Botany, this term is applied to a flower having four stamens.

Tetranthera (Gr. τέτρα, and ἀνθηρός, *flowery*). An extensive genus of *Lauraceæ*, chiefly found in the tropics of the eastern hemisphere, extending, however, as far north as Japan, and as far south as New Zealand, but very few being American. The majority are evergreen trees. In *T. laurifolia*, which is widely dispersed over tropical Asia, the leaves and young branches abound in a viscid juice, and in Cochin China the natives bruise and macerate them until the mass becomes glutinous, when it is used for mixing with plaster to thicken and render it more adhesive and durable. Its fruits yield a solid rank-smelling fat, commonly used in the same country for making candles.

Tetrao (Lat.; Gr. τετράων, *a bustard*). A name selected by Linnæus for an extensive genus of gallinaceous birds, characterised by a naked and generally red band which occupies the place of the eyebrow. This genus comprehended all the various species of grouse, partridges, francolins, quails, and tinamous; and the necessity for subdividing it was consequently soon recognised. Latham restricts the genus *Tetrao* to those species of which the feet are covered by feathers, and are without spurs, with naked toes, and a round or forked tail: these are the true grouse. The species in which the toes are feathered as well as the legs, called *ptarmigan*, form the genus *Lagopus*. Brisson separated from the Linnæan *Tetraones*, the partridges, francolins, and quails, under the generic title *Perdix*; and the obvious characters indicated by the common names of these tribes, have been made by later zoologists the grounds for as many distinct genera. The quails of the New World form the distinct genus *Ortyx*. The long-necked tinamous of America constitute the last genus (*Tinamus*, Latham) of the family *Tetraonidæ*.

Tetrapharmacon. An ointment composed of four remedies; viz. wax, resin, lard, and pitch.

Tetraphyline. A variety of Triphyline, from Keiti in Finland.

Tetrapla (Gr. τετραπλόος, *fourfold*). In Ecclesiastical History, the name of a Bible arranged by Origen in four columns, consisting of four different Greek versions; viz. that of the Septuagint, that of Aquila, that of Symmachus, and that of Theodotion. This work must not be confounded with the HEXAPLA.

Tetrapneumonians (Gr. πνεύμων, *a lung*). The name of a section of spiders (*Araneidæ*), comprehending those which have four pulmonary sacs.

Tetrapterans (Gr. τετράπτερος, *four-winged*). A name applied by some entomologists to the insects which have four wings, and which thus constitute an extensive primary division of the class.

Tetrarch (Gr. τετράρχης). The governor of a fourth part of a country. This was a title granted by the Romans to some tributary princes, whom they did not dignify with the style of king. Such were the sons of Herod the Great, amongst whom his dominions were divided after his death. (*Mém. de l'Acad. des Inscr.* vol. xxviii.)

Tetraspaston (Gr. σπάω, *I pull*). In Mechanics, a machine in which four pulleys all act together.

Tetraspore (Gr. τέτρα, and σπορά, *seed*). One of the forms of fructification found in some sea-weeds. It consists of little clusters of spores, in most cases four in number, but very rarely eight. Mr. Berkeley remarks that fruit of this form seem to be not mere modifications of the capsule, but rather of the nature of gemmæ, multiplying the individual without impregnation. It is called *tetrasporic*, and the separate bodies *tetraspores*. They are usually formed by the division (often unequal) of one globose endochrome, three of the four divisions only being in general visible, in which case the fruit is sometimes erroneously called *trisporic*. When all four are visible at once the division is said to be *crucial*. In some genera, however, the oblong or elliptic endochrome is divided transversely, when the division is called *zonate* or *annular*. The tetraspores may be simply immersed in the frond, when they are called *sori*; or contained in external warts or excrescences (*nemathecia*), or in proper leaflets (*sporophylla*), or, lastly, in elongated pod-like processes (*stichidia*). It is in the rose-spored Algæ that tetraspores are found.

Tetrastich (Gr. τετράστιχος, *in four rows*). In Poetry, a stanza of four verses.

Tetrastyle (Gr. τετράστυλος). In Architecture, a building having four columns in front.

Tetrathionic Acid. An unstable acid of sulphur containing oxygen and hydrogen. Its formula is $S_4O_6H_2$.

Tetter. An eruptive disease of the cuticle. [PSORIASIS.]

Tettiges (Gr. *grasshoppers*). An appellation assumed by the ancient Athenians in allusion to the boast that they were produced from the soil which they inhabited. [AUTOCHTHONS.]

Tettigonians (Gr. τέττιξ, *a grasshopper*). A section of Hemipterous insects, of which the genus *Tettigonia* is the type. It is synonymous with Cicadarians. [CICADA.]

Teucrium (Gr. τεύκριον). An extensive genus of herbs and shrubs belonging to the *Labiatæ*, widely dispersed throughout the world, but abounding chiefly in the northern temperate and subtropical regions of the eastern hemisphere. They are called *Germanders*. Several species were formerly reputed to possess medicinal virtues, but are now discarded except by

rustic practitioners. *T. Scorodonia*, the Wood Germander or Wood Sage, is an extremely bitter plant, with the smell and taste of hops, for which it is said to be substituted in Jersey. Of the other species, *T. Marum*, or Cat Thyme, causes sneezing, and was formerly employed in the preparation of Compound Powder of Asarabacca, but lavender-flowers are now generally substituted for it.

Teutates. In Mythology, a deity mentioned by Lucan (i. 445), in conjunction with Hesus and Taranis, as being worshipped with sacrifices not unlike those of MOLOCH.

Teuthidans (Gr. *τεῦθος, the cuttle-fish*). The family of Dibranchiate Cephalopods, of which the calamary (*Loligo vulgaris*) is the type.

Teutonic. A name assigned to that class of the northern division of the Aryan family of languages, which includes the High German, Low German, and Scandinavian dialects. From the fact that the English speak a low German dialect, it has been inferred that they are, like the Germans, a Teutonic people; but this conclusion, although it may be true, must be received with great caution. It has been already stated [LANGUAGE] that although words may be imported to any extent into the vocabulary of a language, yet the grammatical systems of languages can never be exchanged, and therefore that there cannot be such a thing as a mixed language. But it is not less a fact that a nation may adopt the language of its conquerors, while the new blood introduced by the latter may be altogether inadequate to modify materially the original population; and hence that a race may retain all its characteristics through successive waves of conquest, if the numbers of the invaders in each case bear but a slight proportion to the original inhabitants, and especially if the force of each later invasion falls rather on the previous conquerors than on the original possessors of the country.

There is a strong tendency at the present time to apply these observations to the ethnology of Great Britain; and it is argued that as philology cannot be taken as a sure guide for the ethnologists, we are thrown back on the evidence of history and the bodily and psychical characteristics of the people who form the subject of enquiry; that historical notices give no support to the idea that the numbers of the Roman military colonists were large enough to have any sensible effect on the British population, or that the Roman legionaries were purely Roman; that intermarriages with British women would have a constant tendency to absorb the new element; that if this was the case with the Roman soldiers, it would be so still more with the Saxon invaders, and that while these were too few to effect any material change in the original stock, they would in their turn suffer far more than the British inhabitants from the subsequent inroads and settlements of Danes and Normans; and that the effect of the Norman Conquest in particular would be still further lessened by the fact that the army of William was recruited largely from people closely akin to the British population of England. It is further argued that, although the Britons adopted the language of their Anglo-Saxon conquerors, yet there is a Cymric element in the English vocabulary, and still more that there survives a Cymric pronunciation which is not found among any genuine Teutonic people. It is also urged that a philological examination of Cymric dialects, as the Welsh, reveals a remarkable affinity with Greek dialects in words and forms which are not common to the Greek and Teutonic languages, while the Cymric pronunciation survives among the modern Greeks as among the modern English. It is also argued that the characteristics of the English resemble those of the ancient Briton much more than they resemble those of Teutonic peoples, and that they exhibit the closest resemblance to those of the ancient Greeks. This resemblance may be traced in their common love of athletic exercises, in their pugilistic skill, in their expertness as horsemen, in their excellence as oarsmen, in their horse-races and their hunting, in their prize ring and in their wrestling contests, for which the Cymric word ymsafael corresponds exactly with the Greek *συμπαλαίω*, the *πὺξ ἀγαθὸς Πολυδευκής* being found in the English boxer and prize-fighter.

The conclusion from these and other considerations, it is maintained, is, that the English are a non-Teutonic people, or, in other words, that they represent the original British population of this country, into which has been infused an appreciable, though small, proportion of Saxon, Danish, and Norman blood; and, further, that the English exhibit the highest phase of Celtic civilisation in modern times, as the Athenians and other Greek tribes exhibited the highest Celtic civilisation of ancient times. Whether these arguments are valid and these conclusions correct, it would be premature or rash to affirm; but it will be readily admitted that the enquiry is one of great interest, and that the evidence on both sides should be carefully and impartially weighed. (Pike, 'The English and their Origin,' *Westminster Review*, Oct. 1866, p. 340; *Fortnightly Review*, Oct. 1, 1866, art. 'The Origin of the English.')

Teutonic Languages. A name given to the dialects which are comprised under the High German, Low German, and Scandinavian branches of the Aryan family of languages. Of these, the English and Dutch belong to the Low German branch. These dialects cannot be directly derived from each other, any more than Greek can be derived from Latin, or Latin from Greek, or either of these from Sanscrit; and if they are traceable at all to a common source, this source must be found in a language preceding all dialects which are known to us historically. It need scarcely be said that the language of a tribe or nation is no *conclusive* evidence in questions of ethnology.

Teutonic Order. A military religious order, entitled Teutonic Knights of the Hos-

pital of St. Mary in Jerusalem, which sprang from a peaceful and insignificant beginning during the siege of Acre, in the third crusade. The first founders, in Dean Milman's words, 'were honest, decent, and charitable burghers of Lübeck and Bremen. After the disasters which followed the death of Frederick Barbarossa, when the army was wasting away with disease and famine before Acre, these merchants from the remote shores of the Baltic ran up the sails of their ships into tents to receive the sick and starving. They were joined by the brethren of a German hospital, which had been before founded in Jerusalem, and had been permitted, by the contemptuous compassion of Saladin, to remain for some time in the city. Duke Frederick of Swabia saw the advantage of a German order, both to maintain the German interests and to relieve the necessities of German pilgrims. Their first house was in Acre.' (*Latin Christianity*, book xii. ch. v.) They continued their kindly offices till the crusade of Frederick II., when, under Herman of Salza, the fourth grand master, the order rose to distinction. Their history is from that time transferred to the Baltic, and the interest of their annals centres chiefly in the antagonism of their claims to those of the kings of Poland. The grounds and results of this quarrel are exhibited in minute detail, in the work entitled *Lites ac Res Gestæ inter Polonos Ordinemque Cruciferorum*, edited by Count Dzialynski (Posen 1856).

The knights were invited into Poland by Conrad (regent for Boleslas V.), who sought their aid for the conversion or extirpation of the savage Rutheni, and assigned to them the territory of Culm on the Vistula, for a term of twenty years, as a crusading ground against the enemies of the Christian faith. Of this compact the knights deny all knowledge, but there seems little reason for calling it in question. Retaining possession of their territory, they were further placed by Vladislas IV. in temporary charge of the fortress of Gdansk, which they were to defend against the marquis of Brandenburg. This compact also was broken; and the order was condemned by the legates of Pope John XXII. to restore the fortress and give further compensation in money. For contempt of this sentence they were excommunicated; and Vladislas, finding the papal censures ineffectual, engaged them in the field, and in a battle fought in 1331 is said to have slain 20,000 troops of the order. That the campaign was carried out with frightful severity on the part of the king of Poland, is evident from the total silence of all the witnesses on this subject, in the suit between the order and the Polish kings tried before the legates of Benedict XII., their reply to the protest of the grand master Theodoric being simply the countercharge that the iniquities of the order had led to their summary chastisement. In this trial, which took place in 1339, it was proved that the knights found their way into Dantzig (Gdansk), owing to the weakness of Bogussa, who offered to put them in possession of the fortress until they should receive compensation in money for their aid in guarding the city. In the issue, the knights expelled Bogussa, promising, however, to restore the fort to him as soon as Vladislas paid them the stipulated sum. The next fortress gained by the order was that of Sweckze, which led to the submission of all Pomerania, a territory ceded in 1296 by its duke Mistiwog to King Przemislas. This second suit, like the first, was ended by a papal sentence in favour of the Polish king; but, as before, the sentence was disregarded, and, four years later, Kasimir the Great was obliged to yield up to the order the absolute possession of Cujavia, Culm, and Michalow. A third trial followed, at the council of Constance, when the documents on which the order founded its claims were all impugned, and chiefly on the ground of forgery. But the strength of the order lay in circumstances which could not be affected by ecclesiastical sentences: and thus, while the Knights Templars fell, the Teutonic knights profited by the remoteness of their province, and consolidated their power, until Albert of Brandenburg exchanged his title of grand master for that of Duke of Eastern Prussia, and laid the foundation of the modern Prussian monarchy. (*Edin. Rev.* July 1858.)

The order, however, still remained a separate institution, the seat of the grand master being at Mergentheim, in Swabia. By the peace of Presburg, in 1805, the emperor Francis II. gained the grand mastership with its rights and revenues. In 1809, the order was abolished by Napoleon, but it still has a titular existence in Austria.

Texalite. A variety of Brucite or hydrate of magnesia from Texas in Pennsylvania.

Texasite. A variety of Emerald Nickel from Texas in Pennsylvania.

Textile Fabrics. [WEAVING.]

Textuaries. Among the Jews, the sect of CARAITES, or Karaites, has been so called from its adherence to the text of the Jewish Scriptures.

Thaborites. [TABORITES.]

Thalamifloræ. The name of one of the four large classes into which De Candolle and others divide dicotyledonous plants. It includes all those orders in which the majority of genera have distinct petals, inserted with the stamens on the receptacle, under or immediately around the ovary.

Thalamus (Lat.; Gr. θάλαμος, *a chamber*). In Anatomy, the part of the brain from which the optic nerves have part of their origin.

THALAMUS. In Botany, the part on which the ovary is seated. The succulent red centre of a strawberry, or the core in the fruit of a raspberry, are the thalami of these plants. Some botanists call it the *receptacle*.

Thaler (Ger.). A Prussian silver coin, the value of which, expressed in English money, is 2 shillings and $10\frac{3}{4}$ pence nearly. In a thaler there are 30 silver *groschen*. The word has in other countries been corrupted into *dollar*.

Thalia (Gr. θάλεια, *blooming*). In the Hesiodic *Theogony* (77), one of the nine MUSES, regarded in later times as the muse of Comedy. According to Apollodorus (i. 3, § 4) she was the mother of the CORYBANTES by Apollo.

Thalidans (Gr. Θάλεια, one of the Muses). The name of a tribe of Tunicaries, of which the genus *Salpa* or *Thalia* is the type. [SALPA.]

Thalite. A kind of Soapstone of a pale yellowish-green colour, which is found diffused in the amygdaloidal trap-rocks on the north shore of Lake Superior.

Thallite (Gr. θάλλω, *to bloom*). The name given to certain acicular crystals of Epidote found in France and Spain.

Thallium (Gr. θαλλός, *a young shoot* or *twig*). This metal was discovered by Crookes in 1861, in a deposit obtained from the sulphuric acid manufactory of Tilkerode, in the Harz. (*Phil. Trans.* 1863.) The spectrum of this product furnished a singularly brilliant green line, which led him to examine it further, and suggested the above name. It has since been found in some varieties of pyrites and in the residue of the evaporation of certain mineral waters. It is a soft lead-like metal; its specific gravity between 11 and 12; its atomic weight 204; it tarnishes in the air; fuses at about 560°, and at about 600° takes fire and burns with a green light; in ductility, malleability, and tenacity, it much resembles lead. It forms alloys with most of the other metals. It forms two oxides, the most important of which is the protoxide (=Tl O). This oxide is soluble in water, furnishing an alkaline liquor which absorbs carbonic acid; it is yellow when anhydrous, soluble in sulphuric, nitric, and hydrochloric acids, and is thrown down from its solutions by sulphide of ammonium in the form of a dark brown sulphide. No precipitate is formed in solution of sulphate or nitrate of thallium by the caustic alkalies, but the carbonated alkalies give a precipitate in very concentrated solutions; chlorides, bromides, and iodides, give yellowish precipitates. The salts of thallium are very poisonous; they are colourless, when formed with colourless acids, and are easily decomposed by feeble electric currents.

Thallogens (Gr. θαλλός, *a shoot*, and γεννάω, *to bring forth*). The name of one of the primary divisions of the vegetable kingdom, comprising those cryptogams which are extremely simple in their structure, and exhibit nothing like the green leaves of phænogams. In the few cases in which there are leaf-like expansions, they are not arranged symmetrically round a stem, and are destitute of all trace of stomates and breathing pores; while in those lichens or *Algæ* whose stems are of long duration, though there may be something like centrifugal growth indicated by zones, it is of a totally different nature from that of acrogens The most definite point of distinction consists in the fact that the spores of acrogens when germinating produce either a cellular mass or plant, in which bodies called *archegonia* are formed, which by impregnation produce from an embryonic cell either a new plant or a spore-bearing capsule, while in thallogens no bodies corresponding to archegonia are ever produced.

Thallogens include the two vast tribes of Algals [ALGÆ] and Fungals, of which the latter are divisible into two main divisions, FUNGI and LICHENS.

Thallus (Lat.; Gr. θαλλός). This term, used to indicate a fusion of root, stem, and leaves into one general mass, is applied to that part of thallogens immediately bearing the fructification, more particularly to the cellular mass in which the perithecia are enclosed, or still more especially to the whole vegetative system of lichens.

Thammuz. The tenth month of the Jewish civil year, answering to part of June and July, and containing twenty-nine days. In Mythology, the Phœnician Thammuz is identified with ADONIS, the father (according to one legend) of PRIAPUS.

Thane (Sax. thegn, from thegnian, *to serve*). In early English History, the common title of the Anglo-Saxon military leaders called *Geraths* or companions (from sethian, *to journey*). The ealdormen were comprised among the thanes who are to be regarded as persons who become noble by service, which presupposed freedom of birth. The highest were the immediate thanes or ministers of the king. In Wessex and Mercia these thanes were called *twelf-hynde men*, whose wergild was twelve hundred shillings, i.e. six times that of the *ceorl* or two-hynde man. The dignity was connected with possession of land, the smaller thane possessing five hides, while the ealdorman held forty, this land being regarded as a reward for military service. But, in process of time, the land itself came to be considered a foundation of nobility, and the acquisition of five hides raised the simple freeman from the condition of a ceorl to that of a thane. The merchant who had thrice crossed the sea on his own account became entitled to this rank.

The thane was bound to military service, and obliged to appear on horseback, and had the right of appearing and voting in the witenagemot, the absent being considered as assenting to the resolutions of those who were present. Offices connected with the personal services of the king or the administration of justice were intrusted to thanes whose landed property furnished a sufficient guarantee for his conduct. (Lappenberg, *England under the Anglo-Saxon Kings*, part v.; Turner, *Anglo-Saxons*; Palgrave, *English Commonwealth*; Lingard, *Hist. of England*, ch. vii.)

Thapsia. A genus of *Umbelliferæ*, celebrated in very ancient times for its medicinal products—the Cyrenean Silphium or Laser Cyreniacum being generally supposed to have been the produce of one of the species. They are herbaceous perennials, all natives of the countries bordering on the Mediterranean. *T. garganica*, a native of Southern Europe from Spain

to Greece, and also of Algeria, where it is called Drias, is considered by the natives to be a specific against pain of all kinds, every part of the plant being held to be of equal efficacy. To camels, however, it is a deadly poison. Its root is purgative. *T. Silphium* is found on the mountains in the neighbourhood of the site of the ancient Cyrene, and is supposed to have afforded the gum-resin known to the ancients as *Laser Cyreniacum*, sometimes called *Assa-dulcis* to distinguish it from the assafœtida, both of which were included by the Greeks under the name *Silphion*, as also were other umbellifers.

Tharandite. A greenish variety of Pearl Spar from Tharand in Saxony.

Thatching (A.-Sax. thac; Ger. dach; Lat. tego, Gr. *στέγω, to cover*). Covering houses, stacks, or ricks with straw or reeds, in such a manner as to throw off the rain, and exclude excessive heat, or prevent its escape from within. The straw generally used in thatching is that of wheat, as being the longest and thickest, and the most durable. Next to wheat, rye straw is preferred, or, in default of that, the straw of oats; but the most durable of all thatch in cold countries is that formed of the reed (*Arundo Donax*, Linn.), or of the common heath or ling (*Calluna vulgaris*, Sal.). A very durable covering of the thatch kind is also formed of the spray of birch, of the bark of that tree, or of oak or pine, and of the chips and shavings made by hurdle-makers from the poles and shoots supplied by copse woods. Thatched roofs were formerly almost universal in cottage architecture; but they are now being supplanted by roofs covered with tiles or slates, which are much more durable, and not liable to catch fire; while the straw formerly used for roofs is much more profitably employed as litter for cattle, and thus turned into manure, and employed in reproduction—a process which, in agriculture at least, ought not to be deprived of any material contributing so essentially to its aid as manure.

Thaumatrope (Gr. *θαῦμα, a wonder*; *τρέπω, I turn*). The name given by Dr. Paris to an optical toy, the principle of which depends on the *persistence* of vision. A circle is cut out of a piece of card, to opposite edges of which two silk strings are fixed, by twisting which between the finger and thumb of each hand the disc is turned round with considerable velocity. On one side of the disc is drawn any object, as a chariot; on the other side, the charioteer in the attitude of driving; so that when the card is twirled round, we see the charioteer driving the chariot; or, in consequence of the duration of the impressions of light on the retina, we see at once what is drawn on both sides of the card. (*Library of Useful Knowledge*, 'Optics.')

Thea (Chinese tcha). The Botanical name of the genus of *Ternströmiaceæ* which includes the plants yielding Tea. The native country of the Tea-plant, like that of many others long cultivated by man, is uncertain. Hitherto the plant has been found by botanists in a really wild state only in Assam; and though China has not received so thorough an exploration by botanical travellers as to warrant the conclusion that it does not grow indigenously in that vast empire, yet a Japanese tradition, which ascribes its introduction into China to an Indian Buddhist priest who visited that country in the sixth century, favours the supposition of its Indian origin.

It was at one time commonly supposed that the two well-marked sorts of Tea, Black and Green, were the produce of distinct species; but it has now been ascertained that the Chinese manufacture the different kinds indiscriminately from the same plant; and botanists are now pretty generally agreed that the two supposed Chinese species, called *T. Bohea* and *T. viridis*, are nothing more than varieties of one and the same species, for which Linnæus' name, *T. chinensis*, is adopted, and of which the Assam Tea-plant (sometimes called *T. assamica*) is a third variety, or perhaps the wild type.

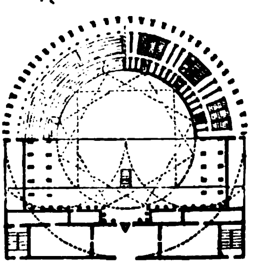
Though the produce of the same variety of the Tea-plant, the Black and Green Teas prepared for exportation are mainly the growth of different districts of China, the Black Tea district being situated in the provinces of Fokein and Kiangsi, and the Green in those of Chekiang and Ngan-whi; but the two kinds may be produced in either district, the difference being caused solely by the diverse methods of preparation. For the manufacture of Black Tea the freshly-gathered leaves, freed from extraneous moisture by a short exposure in the open air, are thrown in small quantities at a time into round flat iron pans, and exposed to gentle fire-heat for about five minutes, which renders them soft and pliant, and causes them to give off a large quantity of moisture; after which they are emptied out into bamboo sieves, and whilst still hot repeatedly squeezed and rolled in the hands to give them their twist or curl. They are next shaken out on large screens, and placed in the open air in the shade for two or three days. They are finally exposed in iron pans to a slow and steady fire-heat until completely dried, care being taken to keep them in constant motion to prevent burning. The chief difference in the manufacture of genuine Green Tea consists in the leaves being so long exposed to the air after rolling that fermentation does not take place, and in not being subjected to such a high temperature in the final drying; but the greater part, if not the whole, of the Green Tea consumed in Europe and America, is coloured artificially by the Chinese to suit foreign trade.

Physiologists are not thoroughly agreed as to the effects of tea upon the human system. Its most active principles are *theine*, a crystalline principle peculiar to tea and coffee, and *volatile oil*, to which its flavour and odour are due, and which possesses narcotic and intoxicating properties; but it also contains fifteen per cent. of gluten or nutritious matter, and more than twenty-five per cent. of tannin. The late Professor Johnstone endeavoured to explain its action by

stating that the *theine* lessened the waste of the body, and consequently lessened the necessity for and thus stood in the place of food, while the gluten actually nourished the body; but Dr. Edward Smith has recently shown these statements to be fallacious, only a trifling proportion of the gluten being taken up by boiling water, and the *theine* promoting instead of retarding vital action, thus increasing the bodily waste. He sums up its action thus: 'It increases the assimilation of food both of the flesh and heat forming kinds, and with abundance of food it must promote nutrition; whilst in the absence of sufficient food it increases the waste of the body.'

Theatines. A religious order in the Roman Catholic church, the earliest of the communities of *regular clerks*; it was founded in 1524 by St. Cajetan of Thiene. The members, besides the ordinary monastic vows, bound themselves to the duties of the cure of souls, preaching against heresies, tending the sick and convicts, while they pledged themselves to abstain from possessing property or asking for alms. (A. Butler, *Lives of the Saints*, August 7.)

Theatre (Gr. θέατρον, from θεάομαι, *I behold*). In Architecture, a building appropriated to the representation of dramatic spectacles. The theatres of the Greeks and Romans display some of the most extraordinary specimens of their power in the arts. (Donaldson's *Theatre of the Greeks*.) They seem to have been carried to perfection in the Greek colonies at an earlier period than they were in the parent cities. The first theatre of *stone* at Athens, called the theatre of Bacchus, was built in the time of Themistocles; and as there seems little doubt that the Athenians were the inventors of the drama as a regular scenic action, it is fair to presume that they were the first to regulate the form and proportions which necessity and pleasure dictated in their arrangement. The subjoined diagram shows the general form of the Greek theatre, which differed but little from



that of the Romans; and the instructions given by Vitruvius in the eighth chapter of his fifth book, as to the general outline of the plan, are as follows: 'Whereas in the Latin theatre the points of four triangles touch the circumference, in the theatres of the Greeks the angles of three squares are substituted; and the side of that square which is nearest to the place of the scene, at the points where it touches the circumference of the circle, is the boundary of the proscenium. A line drawn parallel to this, at the extremity of the circle, will give the front of the scene. Through the centre of the orchestra, opposite to the proscenium, another parallel line is drawn touching the circumference on the right and left; then, one foot of the compasses being fixed on the right-hand point, with a radius equal to the distance from the left point describe a circle on the right-hand side of the proscenium, and, placing the foot of the compasses on the left-hand point, with the distance of the right-hand interval describe another circle on the left side of the proscenium. Thus describing it from three centres, the Greeks have a larger orchestra, and their scene is further recessed. The pulpitum, which they call λογεῖον, is less in width; wherefore among them the tragic and comic performers act upon the scene, the rest going through their parts in the orchestra.' The ancient theatres were frequently used for the deliberations of the general assembly of the people on political matters, as we find from Tacitus and Ausonius. Notwithstanding the employment of those buildings in later times as quarries freely worked by the inhabitants of the cities in which they stood, there are still considerable ruins at Ephesus, Alabanda, Teos, Smyrna, Hierapolis, Cyzicus, Alinda, Magnesia, Laodicea, Mylasa, Sardis, Miletus, Stratonicea, Telmessus, Iasus, and Patara, all in Asia Minor; in Sicily, at Catana, Tauromenium, Syracuse, Argyrium, and Segesta. In Greece, ruins are still extant at Athens, Sparta, in the island of Ægina, at Epidaurus, and Megalopolis. According to Pausanias, the theatre at Epidaurus, built by Polycletus, surpassed all other Greek theatres in its beauty and proportions; but in grandeur and magnificence the Roman theatres far surpassed those of the Greeks; nor is this surprising, if we consider the population the former had to accommodate compared with that of the latter. For a very considerable period the theatres of Rome, like those of the Etruscans, were of wood; and Pompey, on his return from the war against Mithridates, was the first who constructed one of stone. This must have been of large dimensions, as it was capable of containing 40,000 spectators. Some remains of it are still visible. There were two other considerable theatres in Rome: the first built in the year 741 of the city, by Cornelius Balbus; and the second, which was begun by Julius Cæsar, but not finished till the time of Augustus, who dedicated it to his friend Marcellus. From the remains it appears that it was a specimen of great beauty and purity, as far as relates to the profiles of two of its orders, there being no vestiges of the upper order. The only other remains of Roman theatres are at Saguntum and Oranges, though the Romans usually erected theatres in their newly conquered cities, or at least embellished and improved those which they found on the spot.

The modern theatres of Rome are, perhaps, the worst in Europe. Italy, however, boasts

some beautiful examples; the chief being those at Parma (now in a very dilapidated state), Milan, Verona, Turin, Naples, and Bologna. We subjoin a short table of the width of the stage in a few European theatres:—

	feet
Milan	40
San Benedetto, Venice	40
Théâtre Français, Paris	40
Parma	40
Bordeaux	39
Turin	39
Argentino at Rome	36
Théâtre Italien, Paris	33

The properties most valued in theatres are: (1) facility in hearing, which is promoted by bringing the stage well forward into the house, and by forming the ceiling of thin deal like a great sounding board; and (2) safe and easy means of egress by fire-proof stairs in the event of alarm or fire. In the French theatres the ventilation is so regulated that about eighteen cubic feet of air per minute passes through the house for each individual, and the necessary current is sometimes maintained by means of fires. The fresh air is best introduced through perforations near the ceiling, and an air-shaft should be carried up from over the central chandelier for taking the foul air away. In the Prince of Wales' Theatre, in Liverpool, opened in October 1866, the stage is supported on pillars leaning backwards, so as to balance the tendency of the stage to come forward, from the fact of its surface being inclined. The foot-lights, too, are sunk below the level of the stage, which is sloped suddenly down to them, and each foot-light is encircled by a cylinder composed of green, red, and white glass, by turning which, light of either a green or red hue may be thrown on the actors and the scenes.

Thebaia or **Thebaine.** A crystalline alkaloid existing in very small proportion in opium. It has also been termed *Paramorphia.* Its composition is $C_{38}H_{21}NO_6$.

Thebaid. The name given to the heroic poem of Statius, which celebrates the civil war of Thebes waged between the two brothers Eteocles and Polynices. It consists of twelve books. Statius lived in the first century of the Christian era; but scarcely anything is known of his personal history.

Theban Year. In Chronology, the Egyptian year of 365 days 6 hours was so called. [SOTHIAC PERIOD.]

Theca (Gr. θήκη, *a case* or *receptacle*). A term used in Botany in various senses. It is applied to one of the lobes of an anther; to the case or urn containing the spores of mosses; to delicate tubes sunk in the shields of some lichens; and to certain simple kinds of fruit. In all cases it expresses a hollow case. It is now seldom used, except for the spore-vessel of a moss.

Thecaphore (Gr. θήκη, and φέρω, *I bear*). In Botany, the long stalk upon which the ovarium of some plants is seated; as in *Cleome*, and the Caper-bush.

Thecodactylus (Gr. θήκη, *a case* or *chest*, and δάκτυλος, *a digit*). A subgenus of night-lizards or geckoes, distinguished by having the subdigital scales divided by a median groove into which the claw can be retracted.

Thecodont (Gr. θήκη, and ὀδούς, *a tooth*). An order of extinct Sauroid reptiles, distinguished by having their teeth implanted in distinct sockets. One of the genera of this tribe, from the magnesian conglomerate near Bristol, has been called *Thecodontosaurus.*

Thecostomes (Gr. θήκη, and στόμα, *a mouth*). The name given by Latreille to those insects which have a suctorious mouth enveloped in a sheath.

Theft (A.-Sax. thyfthe). In Jurisprudence, the general name for the most ordinary class of offences against property; for which English law uses the peculiar designation of *larceny*. The difficulty of distinguishing between theft and those other species of fraudulent appropriation which are regarded by the laws of most countries as criminal offences, and, finally, that class which is only the subject of civil action, has given rise to a variety of definitions. By the French Code, art. 379, 'Whoever has fraudulently abstracted a thing which does not belong to him is guilty of theft.' By that of Bavaria, art. 209, 'Whoever knowingly of his own accord takes possession of movables not his, without consent of the person entitled thereto, but without violence to anyone, with intent unlawfully to hold the same as his property, is a thief.' As to English law on the subject, see LARCENY.

Theine. A crystalline principle peculiar to tea and coffee and a few other vegetable substances. It is identical with caffeine, has a slightly bitter taste, and is sparingly soluble in cold water and in alcohol. It melts at 454° C., and sublimes at a higher temperature. Caffeine, or theine, is a very feeble base, forming crystallisable salts with sulphuric and hydrochloric acids.

Theism. Etymologically, *theism* is the same word as DEISM; but a distinction is sometimes drawn between them, the name *theist* being applied to those who, while they reject the idea of an external revelation, maintain the existence of a Deity who directs the government of the cosmos by the constant exercise of His beneficent power; the Deist, on the other hand, being defined as one who holds that God, having before creation laid down a law or laws, leaves those laws to execute themselves without further action on His own part.

Thellusson Act. [PERPETUITIES.]

Thelyphthora. [POLYGAMY.]

Theme (Gr. θέμα). A subject proposed for discussion, whether orally or in writing.

Themis. In the Hesiodic *Theogony*, a daughter of Uranus (*heaven*) and Gaia (*earth*). In the Homeric poems she is the embodiment of law and orderly government, convening the council of the gods at the bidding of Zeus. The Hesperides are called daughters of Zeus and Themis.

Thenard's Blue. A compound of a splendid blue colour, obtained by heating a mixture of phosphate of cobalt with pure alumina.

Thenardite. A native anhydrous sulphate of soda, occurring in white, translucent or pellucid octahedrons, aggregated in crusts and druses at Las Salinas d'Espartines near Madrid, and at Tharapaca in Peru. It was named after the French chemist Thenard.

Theobroma (a word coined from Gr. θεός, and βρῶμα, *food*). A genus of tropical American *Byttneriaceæ*, consisting of small trees, with large entire leaves, and solitary or clustered flowers growing from the sides of the old branches and stems, and producing large pentagonal fruits, with a thick almost woody rind, and numerous seeds bedded in pulp.

T. Cacao was the first known species of the genus, and the Cacao or Cocoa of commerce is now usually said to be produced by it, though it is probable that several of the other species afford a considerable portion. Its fruits vary from six to ten inches in length and three to five in breadth, and contain between fifty and a hundred seeds, from which latter Cacao is prepared. When ripe, the fruits turn yellow outside; and they are then gathered by hand, and afterwards split open, and the seeds removed. These are then made to undergo a slight amount of fermentation for the purpose of developing their colour; and are afterwards exposed to the sun daily for about three weeks, or until they are thoroughly dry, when they are packed for exportation.

The cultivation of the Cacao-tree is spread over the greater part of tropical America; but the bulk of the Cacao-seeds brought to England comes from our West Indian colonies, principally from Trinidad and Grenada. To prepare them for use, the seeds are roasted in revolving metal cylinders, then bruised to loosen their skins (which are removed by fanning), and the cotyledons, commonly called *cocoa-nibs*, afterwards crushed and ground between heated rollers. This process softens the oily matter, and reduces them to a uniform pasty consistence. This is then mixed with variable amounts of sugar and starch to form the different kinds of cocoa, or sweetened and flavoured with vanilla or other substances for the formation of Chocolate. As an article of food Cocoa is exceedingly valuable from the large amount of nutritive matter which it contains; but as a refreshing beverage it is much inferior to either tea or coffee, owing to the large amount (50 per cent.) of fat which it contains, and also to the fact that the whole of the substance is taken into the stomach, while with tea or coffee only an infusion is drunk. It contains a peculiar principle which is called THEOBROMINE.

Theobromine. A white bitter crystalline substance contained in cocoa and chocolate (the produce of the fruit of the *Theobroma Cacao*). Its composition is $C_{14}H_8N_4O_4$.

Theocracy (Gr. θεοκρατία). A term expressing the government of a state immediately by God. Thus the government of the Israelites before the appointment of kings is spoken of as Theocratic; the nation, by its choice of an earthly sovereign, being represented as having rejected God, whom alone they had hitherto owned as their king.

Theocrasy (Gr. θεοκρασία, from κρᾶσις, *mixture*). In ancient Philosophy, a term invented to signify that intimate union of the soul with God in contemplation, which was considered attainable by the newer Platonists. Similar ideas are entertained by the philosophers of India, and by many religious sects. [QUIETISM.]

Theodicæa (Gr. θεός; δίκαιος, *just*). A justification of the dealings of Divine Providence with man. A work under this title was published by Leibnitz in the year 1710, in which he endeavours to prove that of all the possible schemes of government which God might have adopted, the one which actually exists in the world is the best. This is commonly known under the name of *optimism*.

Theodolite (a word coined from Gr. θεάομαι, *I view*, and δόλος, *stratagem*). A surveying instrument for measuring the angular distances between objects projected on the plane of the horizon.

In accurate surveying, when the instrument used for observing the angles is a sextant or reflecting circle, or such that its plane must be brought into the plane of the three objects which form the angular points of the triangle to be measured, the altitudes of the two distant objects above the horizon of the observer must be determined, and a calculation is then necessary to reduce the observed angles to the plane of the horizon. The object of the theodolite is to measure the horizontal angles at once, and thereby render the previous calculation, and even the observation of the altitudes, unnecessary.

It is easy to conceive, in a general way, how this object may be effected. A telescope with cross wires in its focus must be mounted so as to be movable both about a vertical and horizontal axis, in order that it may be brought to bear upon any object, whether in the horizon, or above or below it; and the proper means must be applied for measuring, with the utmost accuracy, the angle described about the vertical axis (which is the horizontal angle) in turning the telescope round from one object to another. It is consequently necessary to fix a graduated circle to the vertical axis, with its plane exactly horizontal, and its centre coincident with the vertical axis; and about the same axis a radial bar, firmly connected with the telescope, must revolve parallel to the plane of the circle, for the purpose of indicating the divisions passed over on the limb of the circle when the telescope is turned from the first object to the second. In order also to render the instrument subservient to the purpose of measuring altitudes, a graduated vertical arch is attached to the telescope; but as it seldom happens, in the practice of surveying, that the

objects observed are very much elevated above or depressed below the horizon, or that the vertical angles are required to be taken with the same degree of accuracy as the horizontal angles, the vertical arch is generally only a portion of a circle of smaller radius and less minutely divided than the horizontal circle.

The theodolite, as now generally constructed for the purposes of ordinary surveying, may be described as follows: The horizontal limb or circle consists of two circular plates, which turn freely on each other. The lower or graduated plate receives the divisions of the circle, and the upper or vernier plate has two sets of vernier divisions diametrically opposite. The vertical axis consists of two conical parts, one working within the other. The external part is attached to the graduated plate, and the internal to the vernier plate. The diameter of the under plate is somewhat larger than that of the vernier plate, and its edge is sloped off to receive the graduations; and portions of the opposite edges of the vernier plate are sloped off in like manner to receive the vernier divisions. The graduation is usually to thirty minutes of a degree, but is subdivided by the verniers into single minutes; and in a well-made instrument quarter minutes may be estimated by the eye. For the purpose of adjusting the plane of the circle to the horizon, the external axis is fitted into a ball, which works in a socket between two parallel plates held firmly together by the ball and socket, the under plate being connected with the staff-head supporting the instrument. But this adjustment may also be made (and in larger instruments is usually made) by a tripod support, having a foot screw at each extremity acting against a plate of metal supported by the staff. Upon the plane of the vernier plate are placed two spirit levels at right angles to each other, with their proper adjusting screws, by which the circle is brought accurately into the horizontal plane indicated by the levels. The centre of the circle is adjusted over the point which forms the centre of the station from which the observation is to be made, by means of a plummet.

Instead of the vernier plate described above, the index is sometimes formed by three radial bars connected with the internal vertical axis, each carrying a vernier at its extremity; and a fourth bar carries the clamp, by which the system is secured to the graduated limb.

The horizontal axis of the vertical limb (which is usually a semicircle) is supported by a frame firmly embedded in the vernier plate, and turning along with it about the vertical axis. The telescope has two collars or rings of bell metal, ground to a truly cylindrical form, on which it rests in supports permanently attached to the vertical limb, so that both move together in the vertical plane. The divisions on this limb are read off to single minutes by means of a fixed vernier connected with the frame, and so adjusted that the index points to the zero of the graduated arc when the optical axis of the telescope is truly horizontal. For effecting this adjustment, or determining its index error, a spirit level is attached to the telescope, at one end by a joint, and at the other by a screw, whereby the end is raised or depressed until the air-bubble stands at the middle of the glass tube. The telescope is then reversed; and if the air-bubble of the level still stands at zero, the adjustment is perfect; if not, the index error becomes known by bringing the level to the proper position, and may either be corrected or allowed for in the observations.

In some theodolites the telescope is supported in the manner of a transit instrument; i. e. the telescope and the horizontal axis on which it turns form one piece, and the vertical limb is a complete circle. By this construction the instrument becomes better adapted for determining the altitudes of stars, and consequently for finding the direction of the meridian and the azimuths of objects, or for other astronomical purposes. In fact, it becomes an altitude and azimuth instrument.

In theodolites for common topographical purposes the horizontal circle is seldom more than five inches in diameter; but as the double vertical axis gives the means of carrying round the telescope from the first object to the second without disturbing the graduated circle, and then, by clamping the vernier and graduated plates, of bringing it back, and the graduated circle along with it, to the first object, the measure of the angle may be repeated any number of times, exactly as with the repeating circle, and a very considerable degree of accuracy may be obtained even with a circle of this small size. [REPEATING CIRCLE.] But the principle of repetition is better carried into effect by means of a particular kind of stand or tripod, called a *repeating stand*, which turns round concentrically with the vertical axis of the theodolite; and recourse is usually had to this apparatus when the instrument is on a large scale.

As the accuracy of the observation must depend on the horizontal circle remaining perfectly fixed while the telescope and verniers are turned round, a second telescope, called a *watch telescope*, is sometimes attached to the horizontal circle beneath the limb, which, being directed to a fixed object, serves to detect any disturbance of the circle clamp, or accidental shifting of position while the upper telescope with the verniers is turned from the first object to the second. But this can scarcely be applied to the repeating theodolite.

The principal adjustments of the theodolite are: first, to rectify the line of collimation of the telescope; secondly, to make the axis of the horizontal limb truly vertical; and, thirdly, to adjust the zero of altitude. For the practical methods of making these adjustments in the case of the common surveying theodolite, and instructions as to the mode of observing, the reader may be referred to Simms's *Treatise on Mathematical Instruments*, 1834.

In geodetical operations, where very great

accuracy is indispensable, as, for example, in measuring an arc of the meridian, the instrument is constructed on a much larger scale. The great theodolite by Ramsden, belonging to the Board of Ordnance, which has been used for measuring most of the principal angles of the British Trigonometrical Survey, has a horizontal circle of three feet in diameter, and two telescopes of thirty-six inches focal length. A similar one of equal dimensions had formerly been constructed by the same excellent artist for the Royal Society, and was used by General Roy in his operations for connecting the observations of Greenwich and Paris towards the end of the last century, and also by Colonel Colby and Captain Kater for the same purpose in 1821. A full description of this superb instrument is given in the *Phil. Trans.* vol. lxxx. and in the first volume of the *Trigonometrical Survey of England and Wales.* A theodolite of equal dimensions, by Cary, has been employed in the measurement of the great meridional arc of India by Colonel Lambton and Sir George Everest. The French astronomers, in measuring their arc of meridian, used only the repeating circle; but in the more recent operations of the same kind in Germany and Russia, the geodetical angles were measured with the theodolite.

Theogony (Gr. θεογονία). A history of the descent and relationships of the various gods who were or are the objects of popular worship in the heathen world. In the articles METAPHOR, MYTHOLOGY, POLYONYMY, SYNONYMY, &c. it has been shown that the divinities of the Aryan Pantheon had their origin in mythical phrases relating to sensible phenomena. Men spoke of the sky (Dyaus) [ZEUS] as looking down on the earth, and on the sun as quickening, cherishing, scorching, or destroying all living things, till the names for sun and sky became the names of personal beings who had their abode in either. Gradually the deities so obtained were grouped together, and the sun might be described as the child of the sky [ZEUS], or of night [LêTO]; thus Indra, *the heaven*, became the parent of Ahana or Dahanâ, *the dawn*; and thus the children of Zeus or of Heracles were multiplied until their posterity branched into the genealogies of every tribe, city, or village; and hence the streams of divine and human generation are inextricably blended together. In process of time the task of grouping became a systematic work, which was carried out in various ways, as the mind of the writer led him. Thus the Homeric *Theogony* is far less developed and complete than the Hesiodic, while the latter has far less of a cosmogonical character than the Orphic. Thus, in the Homeric poems, Uranus and Gaia (*heaven* and *earth*) are known as great deities; but they do not appear (as in the Hesiodic *Theogony*) as arch-gods from whom Zeus himself is sprung through Kronos. The Homeric Cyclops is a wild shepherd: the Hesiodic Cyclôpes forge the thunderbolts of Zeus. In the *Iliad*, Briareos rescues Zeus from a conspiracy formed by Hêrê, Poseidon, and Athênê; in the Hesiodic *Theogony*, he helps him in the war against the Titans. In the *Iliad*, Zeus thrusts Kronos and the Titans into Tartarus without any opposition; in Hesiod there is a fierce strife, which in the hands of Æschylus receives its most magnificent colouring in the portraiture of PROMÊTHEUS. Thus the Hesiodic *Theogony*, while more complete, is more retrospective than that of the Homeric poems (whether *Iliad*, *Odyssey*, or *Hymns*), while the Orphic *Theogony* goes back still further to the great mundane egg produced by Chronos (*time*) out of Æther and Chaos. These developements are obviously reached by a systematic backward process, which in greater or less degree characterises all theogonies.

Theologium (Gr. θεολογεῖον). A small upper stage in the ancient theatre, upon which the machinery for celestial appearances was arranged.

Theology (Gr. θεολογία). Like all words expressive of abstruse or immaterial notions, this term may be traced to merely sensible ideas. The Greek θεὸς (the Latin *Deus*) denoted originally the visible heaven or sky [ZEUS]; and thus terms which signify literally the notation of cosmical phenomena have furnished a name for the science which treats of the nature and attributes of God and of His relations to man, or which, as it has been defined by some, gathers up, and combines in a logical form, all that may be inferred from the phenomena of the material and spiritual universe.

Lord Bacon divided this science under the following heads: (1) Inspired; (2) Natural, which he calls the first part of philosophy; (3) Appendices Theologiæ Inspiratæ, i. e. doctrina de legitimo usu rationis humanæ in divinis; doctrina de gradibus unitatis in civitate Dei; emanationes scripturarum; (4) Theologia tam inspiratæ quam naturalis appendix; doctrina de angelis et spiritibus. (*De Augm. Sci.* ii. 1.)

This classification obviously involves the need of a rigid definition of terms. In order to arrive at any clear conclusions, the precise meaning assigned to the words *natural theology*, *inspired theology*, *revelation*, and *reason*, must be exactly ascertained; and the controversies on these subjects seem to have arisen in great measure from the many shades of meaning through which these terms have passed, many of them being used by thinkers on opposite sides, and sometimes even by the same thinker in different senses in different stages of the enquiry.

Thus a definition of the term *natural religion* can scarcely be attained until the idea attached to the word *revelation* has been accurately determined. On the hypothesis that certain truths or facts were imparted to man on his first creation by a method different in kind from that by which he takes cognisance of phenomena and builds up the fabric of inductive science, natural religion resolves it-

self practically into a corruption of an original revelation, unless indeed there are cases in which tribes or nations have become so degraded as to lose every trace of the divine teaching thus imparted. The analogy of nature, according to Bishop Butler (*Analogy*, part ii. ch. ii. § 2), furnishes no presumption against a revelation when man was first placed on the earth; but the question whether mankind had a revelation made to them at that time is, he asserts, to be treated 'as a common question of fact.' If it be asserted that all knowledge of whatever kind is the result of revelation, then the awakening of new ideas in the mind as well as all knowledge gained by the cognition of facts form part of a great scheme of education which is coextensive with the whole existence of mankind from its commencement to its close. In this sense, apparently, Professor Max Müller asserts that the adoption of words to denote degrees of kith and kin marked certain definite stages in the history of the mind and in the moral developement of man; thus the addition of words like *law*, *right*, *duty*, *love*, to the dictionary of man, denoted the acquisition of new ideas, and 'it was a revelation, the greatest of all revelations, when the conception of a Creator, a Ruler, a Father of man, when the name of God, was for the first time uttered in the world.' On this hypothesis, the whole teaching of man becomes a homogeneous process, admitting of no definite line of demarcation between one portion of it and another, and needing only that ordinary sequence of events with which the common experience of mankind has rendered us familiar. The term RATIONALISM is not unfrequently employed to describe this theory, although the fitness of the name has been called in question.

The fact of an original revelation, apart from the normal operations of the mind, being assumed, it becomes necessary to determine the extent of that revelation. To this question Bishop Butler has in his *Analogy* furnished no answer; and by some this primeval revelation is regarded as involving little more than a precept of obedience and the duty of unhesitating submission, founded on the rational relation of God to His creatures. By others it has been maintained that this primeval revelation was supplemented by another immediately subsequent on the fall; that the latter was distinctly dogmatic; and that it set forth the existence (1) of an Infinite Being, whose perfect goodness arose not from external restraints, but from an unchangeable internal determination of character; (2) of a Trinity of Coequal Persons in the Divine Unity; (3) of a Redeemer who should hereafter assume man's nature and deliver from death and sin; (4) of a Divine Wisdom, which was with God from the beginning; and (5) of an Evil One who, having fallen from his throne in heaven, had become an antagonistic power, tempting men to their destruction.

These conclusions have been regarded by some writers as furnishing a key to all mythological systems, and especially to that of the Greeks, who converted the Trinity revealed to Adam into a Trinity of the three sons of Kronos, Zeus, Hades, and Poseidon, the tradition of the Redeemer being represented in Apollo, that of the Divine Wisdom in Athênê. To this it has been replied, that if the subject of the original revelation must be judged, in Bishop Butler's words, 'as a common question of fact,' its extent can be ascertained only by an impartial and unprejudiced examination of the documents in which it is embodied; that the statements of the book of Genesis do not propound the dogmatic belief involved in this hypothesis; that they speak only of one positive prohibition, of a beast which tempts the woman to disobey that command, of an attempt to transfer the blame from the man to the woman, from the woman to the serpent, of a sentence passed upon the latter that its head should be bruised by the woman's seed, and of a life of evil and labour imposed on the former, to be closed finally by a return to the dust from which man had been made; and that a dogmatic revelation of so minute a kind as that which many have discerned in the third chapter of Genesis would have been unintelligible to those who received it, and would soon have faded from their memory. To that interpretation of mythology which rests on this hypothesis, it has been replied that a few only of the characteristics of these mythopœic systems are thus accounted for, that these characteristics can be as well, if not more satisfactorily, accounted for in other ways, and further that, if the mythology of the Greeks or other races is a corruption of a primeval revelation, the ideas which were thus distorted and corrupted must have become fainter with the lapse of time; that truths thus perverted cannot become clearer and more definite in the process of corrupt developement; that the early literature of Greece exhibits a constantly increasing, not a decaying, sense of the Unity of the Divine Nature, and that the morality and philosophy of the Hesiodic poems is immeasurably higher, not lower, than that of the Homeric poems of a much earlier age; and that in point of fact the progress of man through POLYTHEISM to MONOTHEISM was very different from the course which the theory of a corrupted revelation would assign to it.

In another aspect, the subject of revelation is connected with that of the SUPERNATURAL. It is manifest that the hypothesis of relative miracle and the idea of absolute miracle are each equally consistent with the position that the increasing ignorance and corruption of man rendered it necessary that the Deity should interfere in order to recall them to obedience and a life of goodness or penitence; that these interferences were especially manifested in the history of the Jews, and culminated in the miracles which attended the preaching of the Gospel; and that this last and highest revelation was announced by a long series of prophets, who predicted the life, sufferings, and death of the Saviour. The arguments chiefly urged against these positions are found in the counter state-

ments that relative miracle, as being confessedly the manifestation of a higher law, cannot strictly be regarded as miracle at all; that the idea of absolute miracle is excluded by the notion of relative miracle, and that, if the latter idea had been set before the writers of the Old Testament or the New, the miracles which they related would in their eyes have lost all value and significance; that the actual occurrence of these events must be ascertained by an examination of the narratives, and must be treated as 'a common question of fact;' that the true idea of prophecy, as set forth in the book of Jonah, is not prediction, but the enunciation of a righteous law, and that the foresight of the Hebrew prophets was strictly the result of their observance of that law; and that the statements which are regarded as predictions relating to a remote future time were concerned only with the events or the results of causes at work in their own day.

These antagonistic opinions rest on conflicting notions of inspiration. These ideas have exhibited many phases, and have from time to time undergone indefinite modifications; but they may all be resolved ultimately into the conviction, on the one hand, that the inspiration of the prophets was different in kind from that by which men ordinarily are brought to the knowledge of moral and spiritual truth, and, on the other hand, that it differed from the latter only in degree.

A further antagonism is exhibited in opinions on the functions of the human mind in the cognition of truth, or, in other words, on the real relation existing between God and man. Thus by Mr. Mansel, following Sir W. Hamilton, it has been maintained that men are incapable of conceiving an Absolute and Infinite Being, and that, if they attempt to do so, they fall into self-contradiction; that men are, nevertheless, bound to believe in the existence of such a Being, while from the impossibility of our conceiving or knowing God's essential attributes, we are disqualified from judging what is or is not consistent with them. This position involves, it is said, the conclusion that, 'if a religion is presented to us containing any particular doctrine respecting the Deity, our belief or rejection of the doctrine ought to depend exclusively upon the evidences which can be adduced for the Divine origin of the religion; and no argument grounded on the incredibility of the doctrine as involving an intellectual absurdity, or on its moral badness as unworthy of a good and wise Being, ought to have any weight, since of these things we are incompetent to judge.' The question of the evidence to be adduced in favour of any system of religion is obviously a matter of history: the capability or incapacity of man to conceive of an Infinite Being is strictly a question of metaphysics; and on the latter, Mr. J. S. Mill (*Examination of Sir W. Hamilton's Philosophy*, ch. vii.) has replied that the idea of an Absolute Being is the idea of a Being *capable of existing out of relation to anything else*, whereas, in order to establish the human incapacity of conceiving such a Being, the definition should set forth an Absolute Being as one who is *incapable of existing in relation with anything else*; that this position is not maintained by any, inasmuch as all agree in speaking of the relations of God with the world and with man; that possible existence out of all relation is not incompatible with the notion of the Divine Being as a cause, or as absolute, just as the sun may be conceived as existing without any earth or planets to be illuminated by it; that anything which is capable of existing in relation is capable of being conceived or known in relation; that, if the Absolute Being cannot be conceived as cause, it must be that He cannot exist as cause, i. e. He must be incapable of causing; that, if an Absolute Being is unknowable in Himself, the relative attributes of an Absolute Being are unknowable likewise; that on this hypothesis, we do not know what wisdom, justice, and mercy are, as they exist in God; that, in applying these words to denote Divine attributes, we do not mean what the words assert, but something else, and that in this case we have no right to call them by names employed to denote certain qualities in man; that, if in affirming them of God, we do not mean to affirm the very same qualities which are found in man, differing only as greater in degree, we are neither philosophically nor morally entitled to affirm them at all.

But while the Eastern and Western Churches agree with most of the Protestant societies in maintaining that man, created pure and sinless, has, by a great aboriginal catastrophe, fallen from his first estate, and needs a complete renewal of his nature before he can be acceptable to his Maker, there is a wide difference between the theories on the mode and means by which this regeneration is effected. While Catholic and Protestant theologians alike agree in holding that man after the Fall needed the intervention of a Mediator, who should by the sacrifice of Himself atone for human disobedience, and in whom penitent sinners should be justified before God, the system which the former have raised on this basis differs widely from that of the latter. According to the Catholic belief, all mankind are by nature the children of wrath; by baptism they become children of grace, members of Christ, and inheritors of the kingdom of heaven. In this sacrament of admission into the Christian Church, they are brought to the laver of regeneration, and their nature undergoes a complete renewal. The grace thus received may be accepted thankfully or resisted; but, in the latter case, true penitence becomes the means for restoration to blessings already received, not for the obtaining of blessings to which hitherto they had been strangers. Hence the baptised child is taught that all that can be done for him has been done already, that the old things have for him passed away, and that he is a new creature; that, if by his own fault he goes away into the enemy's country and wastes his substance in riotous living, he may return to the house of his Father, from which he

has strayed, but that, while he can return to his original state of grace, he cannot possibly by penitence pass into a condition different from that which had become his birthright in and by baptism. Thus the sacrament of initiation imparts life; and a sacrament only can sustain the life thus imparted, and this sustenance is afforded in and by the Holy Eucharist. Thus the life of the Christian is wholly sacramental, being based on the mediatorial and priestly character of Christ, who is the only true priest exercising a divine and changeless priesthood. Christ alone has offered the only sacrifice which ever possessed the least power and virtue in itself; and by the offering of Himself once for all upon the cross, He paid back to the Father the ransom for all the sons of Adam, and atoned for the whole weight of sin brought in by Adam's fall. And further, as He only is a priest by His own inherent power, so by the virtue of His own priesthood they who are priests on earth exercise their office. They plead before God in the priesthood which Christ has Himself bestowed upon them, the sacrifice of His body and blood, so that the things which they do, they do not of themselves, but Christ performs them by their hands.

The mediatorial idea is thus made to pervade the whole province of theology. Man of himself cannot approach God; he can come near to the Father only through Him who is the Way, the Truth, and the Life. But He has appointed certain means, and insists on the performance of certain conditions. He has founded an organised society, in which alone the Christian can have assurance that he is receiving the spiritual food which is necessary to his soul's health; He has chosen certain men to whom He has delegated His own priestly powers, and charged them to admit others to their office, by the laying on of hands, to the end of time. These are the appointed stewards of His mysteries and ministers of His sacraments, the visible agents by whom He exercises His mediatorial functions. Thus in the world there is an order of men wielding powers which have not come to them from any earthly source, and kept up in an unbroken series which has received the name of the *apostolical succession*. [SUCCESSION, APOSTOLICAL.] From this doctrine the necessity of communion with the Catholic Church flows as a necessary consequence. Except under the condition of invincible ignorance, it is not enough to have a lively faith, or to do right acts; the Christian must exercise this faith and perform these acts where alone he has assurance that they will be effectual. Hence, for each person it becomes a truth that beyond the church there can for him be no salvation. But as to the nature of Catholic communion, there are large differences of opinion. According to the Orthodox (or Greek) and the Anglican theologians, all those societies which maintain the apostolical succession, and hold all that has from the beginning been declared to be 'of faith,' and in which the sacraments are rightly administered in form and matter, are portions of the Catholic Church, which is one in faith and practice, although divided by unhappy schisms which have sundered East and West, and compelled the Anglican Church to reject the Roman developements and assumptions. In opposition to this theory, Roman Catholic churchmen insist that under no circumstances can there be any warrant for schism, inasmuch as the grace given to the vicars of Christ is indefectible, that the church founded on the see of Peter is the eternal church against which the gates of hell shall never prevail, and that, as the Roman Church has in itself an absolute guarantee of infallibility, all resistance to its decrees and rejection of its claims to universal allegiance is without excuse.

With this system the Lutheran, Calvinistic, Zuinglian, and other Protestant theories are more or less antagonistic. The objections of Zuinglius himself were apparently far deeper than those urged by any other of the Reformers; but the latter as a body agreed in teaching that the mediatorial office of Christ was not exercised by a continual representation, on earthly altars and by the hands of a visible priesthood, of His own sacrifice on Calvary. As a body, they rejected the sacerdotal hypothesis; and although they still held that the sacraments were necessary or important means of grace, they maintained that their efficacy lay not in the right administration by a priesthood tracing its succession in unbroken line to the apostles, but only in the personal condition of the recipient. In their theory, all the children of Adam remained children of wrath and unfit objects for Divine love until they had been regenerated by a conscious personal conversion from unrighteousness to God. This regeneration was the direct gift of the Holy Spirit, which might be obtained before or after baptism, or possibly at the moment of baptism, but which in no case was tied up with baptism, or was its necessary consequence. The one indispensable condition was a lively or saving faith, *fiducialis apprehensio Christi*; and with the existence of this faith all other considerations became superfluous. This system necessarily interfered with the Catholic idea of Church communion, of Church discipline, of ritualism and ceremonies and its adherents, holding that the Catholic churches had corrupted the simplicity of the Gospel of Christ, made themselves the judges in the last resort of the nature and contents of that Gospel. They thus laid themselves open to the charges urged by their opponents, that on their own authority they presumed to run counter to the authority of that which alone could claim to be the Church of Christ, and that thus their basis involved the principle of scepticism and infidelity.

With these antagonistic theories has coexisted, possibly in all ages, a condition of thought which has been more especially characterised as rationalistic [RATIONALISM], and which has raised a protest not only against sacerdotalism, but against the system which especially claims the sanction of the Bible.

This school, if it can be termed a school, rejects in greater or less degree the ideas on which a sacrificial or mediatorial religion is ultimately based, and, asserting that God has in all ages and countries been educating the whole human race, declares that He desires for all men their highest good, and that this, the desire of a Mind which can feel no passion and know no change, must in the end be accomplished. Hence the final well-being of all mankind is insured by the very necessity of the Divine nature; and thus the distinction between a natural and a revealed religion becomes meaningless rather than superfluous. In points of detail, it asserts that the doctrines taught whether by Roman Catholics or by Protestants are inconsistent with ascertained facts or with the analogy of nature, and that in some instances, as by declaring that all persons dying impenitent will be endlessly tormented, they are degrading and demoralising. Such thinkers fall back, in short, on the examination of facts and the analysis of the ideas involved in such terms as law, education, punishment, justice and righteousness, and take their stand on the ground from which, as we have seen, Mr. Mill opposes the authoritative method of Mr. Mansel.

The preceding remarks may serve to give some idea of the three great lines of thought which are exhibited in the history of Christianity. We can only remark, further, that the subject of *natural* religion, as contrasted with a system promulgated on external authority, forms the basis of Bishop Butler's treatise on *Analogy*. His argument is chiefly negative, and rests on the statements that probability is the guide of life, that the evidence of religion is fully sufficient for all the purposes of probation, and that it would not answer the Divine purpose if it were as overbearing as is required, and that thus 'a serious apprehension that Christianity may be true lays persons under the strictest obligations of a serious regard to it throughout the whole of their life, a regard not the same exactly, but in many respects nearly the same with what a full conviction of its truth would lay them under.' This reasoning has not passed unquestioned; and in particular it has been urged that the natural world does not exhibit the analogy on which Bishop Butler lays so much stress, that no true scientific method puts aside exceptions or seeming irregularities as things which need not be regarded, or which may be better put out of sight; that true scientific method is never content with probabilities, but aims incessantly at the ascertainment of actual facts; that the progress made by man in civilisation may be measured by the degree in which he has attained to the knowledge of facts; that the course of nature suggests the idea of a Being who requires not an unquestioning obedience, but the full exercise of every mental faculty; and that the process of systematising without reference to certain known or acknowledged exceptions or difficulties is not admissible in true scientific method.

The opinions of theologians on the subject of human life and the condition of men after death are noticed in the article SOUL. The several tenets of dogmatic theology are treated under their respective headings.

Theopaschites (Gr. θεός, and πάσχω, *I suffer*). In Ecclesiastical History, a name given by the orthodox to the followers of Peter the Fuller, a usurping bishop of Antioch in the fourth century. Being strongly attached to the Monophysite opinions, he was charged with holding that all the three Persons of the Godhead were crucified. (Mosheim, fifth cent. part ii. ch. li.)

Theophany (Gr. θεοφάνεια). A word invented to signify the manifestations of God to man by actual appearance. These have formed a striking feature in most systems of religion. (See, on Pagan Theophanies, the fifth Dissertation of M. Foucher on the Hellenic Religion, *Mém. de l'Acad. des Inscr.* vol. xxxvi. p. 292.)

Theophilanthropists (Gr. θεός, and φιλάνθρωπος, *a lover of men*). A title assumed by a society formed at Paris during the first French revolution. The object of its founders was to establish a new religion in the place of Christianity, which had been formally abolished in France by the Convention, and had lost its power over the minds of large classes of the people. The Directory granted these philosophical sectarians the use of ten parish churches in Paris, where they held meetings for religious service; but the attempt to found a new sect was wholly unsuccessful. In 1802 they were forbidden the use of the churches by the consuls, and then ceased to exist.

Theophrastaceæ (Theophrasta, one of the genera). A small order proposed by Alphonse De Candolle for *Theophrasta* and a few other small genera, usually included in *Myrsinaceæ*, from which they differ chiefly in the presence of scales in the throat of the corolla, alternating with its lobes. They are generally regarded as a tribe of *Myrsinaceæ*.

Theorbo (Ital. tiorba). A lute of large dimensions, sometimes called the *arch-lute*, and formerly used for striking the chords of the thorough bass in accompaniments.

Theorem (Gr. θεώρημα, literally *a sight*). In Algebra, a theorem is frequently expressed by a formula, as in the BINOMIAL THEOREM and TAYLOR'S THEOREM. In Geometry, *theorems* are proposed for *demonstration*; they are thus distinguished from *problems*, in which a construction is proposed and a *solution* required. In Mathematics, a theorem is an expressed relation or truth.

Theoric Fund (Gr. τὰ θεωρικά, sc. χρήματα, literally *money for sights*). At Athens, the surplus of ordinary revenue, after defraying all charges of the peace establishment, was devoted to the formation of a fund for furnishing to all citizens not absent from Attica the sum (2 oboli) required as the price of seats at the great dramatic festivals. This gratuitous distribution of money (a measure carried by Pericles) was

made not from a mere purpose of insuring or increasing the pleasures of the citizens, but chiefly as a religious duty, the drama being in fact a solemn service offered in honour of the gods. This religious character extended to all Hellenic festivals; but the theoric fund, called by Mr. Grote the church fund of Athens, is perhaps the only instance of a charge laid upon the state for all expenses incurred in the worship of the gods. It was expressly provided that this fund should not be diverted to war purposes; and Demosthenes struggled for twelve years to apply these resources to the defence of the state, and succeeded only on the eve of the fatal battle of Chæroneia. (Grote, *History of Greece*, part ii. ch. lxxxviii.)

Theory (Gr. θεωρία). In Art, this word denotes the abstract principles of any art, considered without reference to practice.

Theory. In Science, this term properly expresses a connected arrangement of facts, according to their bearing on some real or hypothetical law. An *hypothesis* has been distinguished from a theory as an assumption which is conceived to afford a *support* to the discovered law. Thus some have imagined that the facts of gravitation are explained on the supposition of a subtle and all-pervading ether. Here it is evident that the *facts*, and therefore the *theory* or connected survey of them, are unaffected by the *supposition* in question.

Theosophists (Gr. θεόσοφος, *wise in the things of God*). A name which has been given, though not with any very definite meaning, to that class of mystical religious thinkers and writers who aim at displaying, or believe themselves to possess, a knowledge of the Divinity and His works by supernatural inspiration. In this they differ from the mystics who have been styled *Theopathetic*, whose object is passively to receive the supposed communication of the Divinity and expatiate on the results. [Mysticism.] The best-known names at this day of the Theosophic order are those of Jacob Böhme, Madame Guyon, Swedenborg, Saint-Martin. Schelling and others, who regarded the foundation of their metaphysical tenets as resting on divine intuition, have been called Theosophists, but with less exactness.

Therapeutæ (Gr. θεραπευταί, *worshippers*). A Jewish sect of the first century after Christ, who, with the Essenes, were the ancestors of the Christian monks and hermits. (Milman, *History of Christianity* i. 162; Montalembert, *Les Moines d'Occident*.)

Therapeutics (Gr. θεραπευτικός). The science which treats of the application of remedies, and the curative treatment of disease.

Theriaca (Gr. from θήρ, Ger. thier, Eng. deer, Lat. fera, Ger. eber, Eng. bear and boar, all denoting originally *a beast* [Treacle]). A name given in ancient Pharmacy to certain complex remedies supposed to be antidotes to poisons; they were usually in the form of confections. Some of the more celebrated have been transferred to comparatively modern pharmacopœiæ; such as the *Theriaca* of Andromachus, *Theriaca, Veneta Confectio Mithridatis*, &c.

Thermæ. [Bath.]

Thermal Springs. [Springs, Mineral; Springs, Thermal.]

Thermidor. In the French Calendar, the name of the eleventh month of the year in the French Republic. It commenced on July 19, and ended on August 17. The name is derived from the Gr. θερμός, *warm*, and was borrowed from the great heat which characterises that period of the year. It was the month signalised by the overthrow of Robespierre and the Reign of Terror, thence commonly called the Revolution of Thermidor; and those who boasted of having participated in it called themselves Thermidorians.

Thermo-electric Pile. An instrument composed of a number of alternate bars, generally of bismuth and antimony, by which small changes in temperature are rendered sensible by the production of an electric current, the presence of which is shown by means of a galvanometer. The thermo-pile was first constructed in a compact and efficient form by

Nobili, in 1834; but Melloni first applied this instrument to researches on radiation, for which purpose it has been invariably used since his time, as in its delicacy and accuracy it far exceeds all other thermoscopes. The figure represents a thermo-electric pile as used for investigations in radiant heat. One face of the pile A is bared to show the disposition of the bismuth and antimony bars, the ends only being seen. Attached to the other face is a conical reflector, C, which converges the radiant heat on to that face of the pile, where it is absorbed by a coating of lamp-black. The wires coiled down the sides, but insulated from the instrument, convey the electric current thus generated to the binding screws in the base B, whence the current is led by the wires *w w* to a neighbouring galvanometer. The action of the pile will be understood by a reference to the article Thermo-electricity.

Although the present use of the thermo-electric pile is confined to thermometric purposes, recent experiments lead to the hope that

it may at last become a powerful and profitable source of electricity. Prof. Bunsen, combining either copper pyrites or pyrolusite with copper, has obtained a battery, ten pairs of which give all the effects of a small Daniell's cell.

A *thermo-electric battery* has also been constructed by M. Marcus of Vienna, who employed for the positive metal an alloy composed of—

	parts
Copper	10
Zinc	6
Nickel	6

and for the negative metal an alloy of—

	parts
Antimony	12
Zinc	5
Bismuth	1

The bars of this battery were about six inches long and half an inch broad; the opposite junctions were heated by gas jets, and cooled by a current of water. With several pairs of such a battery a spark can be seen on closing the circuit, acidulated water decomposed, a metal electro-plated, an electro-magnet excited, and a piece of fine platinum wire can even be fused.

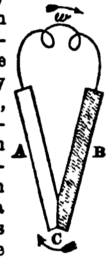
Thermo-electricity. When the junction of two dissimilar metals is heated or cooled, the free ends being joined by a wire, an electric current is generated. This developement of electricity by heat was discovered by Prof. Seebeck in 1822, and has received the name of *thermo-electricity*: in its theoretical and practical applications it is a fact of great importance.

The intensity of the thermo-electric current depends on two things: the nature of the metals employed, and the difference in temperature which exists between the two ends of the metal bars. The metals have been found by experiment to stand in the following thermo-electric order:—

Bismuth	Platinum
Nickel	Silver
German silver	Zinc
Brass	Iron
Lead	Antimony
Tin	Tellurium
Copper	Selenium

If two of these metals be taken, the more distant their position in the list the stronger is the current that will be generated. Hence the electro-motive force of bismuth and selenium is the greatest; but as it is generally impracticable to employ the last two metals on the list, bismuth and antimony form the usual thermo-electric couple.

The direction of the current can be understood by reference to the annexed figure. A represents a bar of antimony, B a bar of bismuth, the couple being soldered at the point C, and united by a wire *w*. On heating the junction C a current is generated, which moves in the direction of the arrow, i. e. from bismuth to antimony through the junction, and from antimony to bismuth along the connecting wire. On the other hand, if C be chilled, the current is reversed, now passing from antimony to bismuth across the junction. By uniting several of these couples so as to have alternate bars of bismuth and antimony soldered at their ends, the strength of the current can be greatly increased. Thus multiplying the number of pairs, and compactly arranging them in a cubical shape, Nobili constructed the first *thermo-electric pile*, an instrument which has become invaluable in researches on radiant heat. When one end of such a pile is heated, a current is produced which moves in the opposite direction when the other end is warmed. The existence of a current, therefore, depends, as already stated, upon the difference of temperature between the two opposite faces of the pile, and within certain limits the strength of the current is exactly proportional to this difference. It is on this account that the thermopile has become so important a thermoscope.



Thermo-electric currents can also be produced in a circuit formed of a single metal. If a straight and homogeneous wire be heated, no current is produced; but if the wire be coiled or knotted, a current will at once flow from the heated part to that in which the homogeneity has been destroyed. Two pieces of bismuth or two of antimony will also generate a current, if so placed together that their crystals shall occupy different relative positions. The origin of the thermo-electric current is probably to be found in the unequal propagation of heat in a conducting circuit. The electricity is not created; it results from the disappearance of an equivalent amount of heat. This can be confirmed by causing one face of a thermo-pile to be surrounded with water, whilst the other face is heated: the water becomes more rapidly warmed when the circuit is broken than when closed. A portion of the heat, which is conducted through the metal bars to the water in the former case, disappears in the latter, having been converted into electricity. This is further shown by a remarkable experiment of Peltier's, who found that cold was produced at a bismuth and antimony junction, when a current of electricity was sent from bismuth to antimony, and heat produced when the current was reversed.

Thermometer (Gr. θερμός, and μέτρον, *measure*). An instrument for measuring variations of temperature.

The principle upon which thermometers are constructed is the change of volume which takes place in bodies when their temperature undergoes an alteration. Generally speaking, all bodies expand when heated, and contract when cooled, in such a manner that, under the same circumstances of temperature, they return to the same dimensions; so that the change of volume becomes the exponent of the temperature which produces it. But as it is necessary not merely that expansion and contraction take place, but that they be capable of

being conveniently observed and measured, only a small number of bodies are adapted for thermometrical purposes. Solid bodies undergo so small a change of volume with moderate variations of temperature, that they are in general only used for measuring very high temperatures, as the heat of furnaces, of melting metals, &c. Instruments for such purposes are distinguished as *pyrometers*. [PYROMETER.] The gases, on the other hand, are extremely susceptible of the impressions not only of heat and cold, but also of pressure; and as their changes of volume are great even with moderate accessions of heat, they are adapted only for indicating very minute variations, or for forming *differential* thermometers. [DIFFERENTIAL THERMOMETER.] Liquids hold an intermediate place, and, by reason of their moderate but sensible expansion through the ranges of temperature within which observations have to be made for by far the greater number of purposes, are commonly used for the construction of thermometers; spirits of wine and mercury being the liquids most generally employed.

The properties which render mercury preferable to all other liquids (unless for particular purposes) are these: 1. It supports, before it boils and is reduced to vapour, more heat than any other fluid, excepting certain oils, and endures a greater cold than would congeal most other liquids, excepting certain spirituous liquors. 2. It takes the temperature of the medium in which it is placed more quickly than any other fluid. 3. The variations of its volume within limits which include the temperatures most frequently required to be observed may be presumed to be regular, and proportional to the variations of temperature. The spirit thermometer is used for observations of very low temperatures, or as a self-registering instrument for meteorological observations.

Construction of the Mercurial Thermometer.—A glass bulb, having a slender hollow tube attached to it, is filled with mercury, so that expansion or contraction can take place only by the rise or fall of the liquid in the tube. The diameter of the tube may be of any convenient size; but the smaller it is the larger will be the scale of the variations; and capillary tubes are usually employed. It is essential that the diameter of the bore be of a uniform width throughout; a quality which is tested by drawing up into the tube a short column of mercury, and measuring its length at the different parts with a pair of compasses. Not more than a sixth part of the tubes which come from the glass-house are found to be fit for the purpose.

Having selected a tube, the workman begins by blowing a hollow ball A upon one extremity of it, by means of an air-bag of caoutchouc (in order to avoid the introduction of watery vapour by blowing from the mouth). The length which the thermometer is to have is then marked, and above this point the tube is expanded into a second bulb B, rather larger than the first. When the tube has acquired its natural temperature, one of the bulbs is warmed, in order to expel the air from it, and the open end of the tube is plunged into distilled and well-boiled mercury. During the cooling, the mercury rises into the second bulb B, whence it is made to pass into A by placing this undermost, and expelling the air from it by heat, after which the mercury descends, from the effect of cooling. When the bulb A has been completely filled, and also a part of B, the tube is suspended horizontally over a fire, so as to be equally heated throughout, and the enclosed mercury boiled, in order to expel every remaining particle of air or humidity. The open end is then touched with sealing-wax, and the tube withdrawn from the fire, and placed in an upright position until it is cooled, when the bulb A and the portion of the tube under B will be filled with mercury. A portion of mercury is then expelled by heat, so that the column may stand at the proper height in the tube. The tube is then permanently closed by the blowpipe flame, at a point immediately below the bulb B, which is thus removed.

Fig. 1.

Graduation of the Scale.—In order that different thermometers may be comparable with each other, it is necessary that two points at least be taken on the tube or stem corresponding to fixed and determinate temperatures, the distance between which will determine the graduation. The two points which are now universally chosen for this purpose are those which correspond to the temperatures of freezing and boiling water. For the former, the bulb is surrounded by ice, and the stem marked at the point to which the mercury contracts; for the latter, the bulb is placed near to the surface of boiling water, and the stem marked at the point to which the steam has caused the mercury to rise. Several other minute circumstances must be attended to in the construction of delicate instruments.

The interval between the two fixed points on the stem may be divided into any number of degrees at pleasure, and the graduation continued above and below as far as may be thought requisite: the numeration may also be begun at any point whatever on the scale; but there are three methods of division so generally adopted as to require particular notice. The first is Fahrenheit's, which is used in this country, in Holland, and North America; the second, Réaumur's, which was formerly in general use in France, and is still followed in Spain, and some parts of Germany; and the third, that of Celsius, or the centigrade scale, now used in France, Germany, Sweden, and generally by scientific men in all parts of the world. In Fahrenheit's scale the interval is divided into 180 parts or *degrees*, as they are commonly termed, and the zero point is placed at thirty-two similar distances below the freezing point of water. The latter temperature was the lowest observed in Iceland, and was

erroneously supposed to be the lowest obtainable. In Réaumur's scale the interval is divided into eighty degrees, and in the centigrade into 100, a number recommended by its simple decimal character. To convert the degree of temperature on one scale into the corresponding one on either of the others is obviously only a matter of calculation, the following formulæ being as convenient as any:—

$$\begin{array}{l} C. \div 5 \times 9 + 32 = F. \\ R. \div 4 \times 9 + 32 = F. \\ F. - 32 \div 9 \times 5 = C. \\ F. - 32 \div 9 \times 4 = R. \\ C. \div 5 \times 4 = R. \\ R. \div 4 \times 5 = C. \end{array}$$

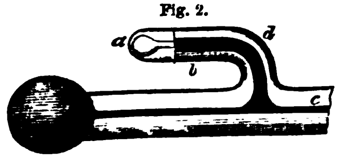
For temperatures below the freezing point, the calculations from or into Fahrenheit's degrees will of course be slightly modified. Thus, for the former, the division and multiplication will be made on the number obtained on previously subtracting the degree from thirty-two, and for the latter the number obtained on division and multiplication must be finally subtracted from thirty-two.

Register Thermometers.—In meteorological observations, it is of great importance to ascertain the limits of the range of the thermometer in a given period of time, during a day or night, for example, while the observer is absent. Many contrivances have accordingly been proposed for this purpose, but the two following are those most frequently used.

Phillips' Maximum Thermometer.—This is an ordinary mercurial thermometer with about half an inch of the mercury separated from the remainder in the stem by a minute particle of air. The detached portion is called the *index*, and remains in the part of the tube to which it may have been propelled by the expansion of the mass of the mercury, thus showing the greatest degree of heat to which the instrument may have been exposed in a given time. The index is made to recede or fall—or *set* as the operation is termed—by a dexterous jerk. Of course this thermometer must be suspended horizontally.

Casella's Mercurial Minimum Thermometer.—In this instrument the mercury falls during cooling, as usual, but does not rise again in the indicating stem, its expansion being provided for by a side outlet, as seen in the accompanying figure at *d*. This thermometer is filled with mercury as already described, but is graduated when the fluid occupies every portion of the

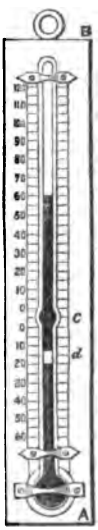
Fig. 2.



lower part of the instrument *except* the little pyriform chamber *a*. When it is suspended horizontally, and the little chamber emptied of its mercury by tilting up that end of the instrument, contraction on cooling will take place in the direction of least resistance, viz. down the long stem *c*, for the mercury is retained in the side tube *d* by a large amount of adhesion at the diaphragm *b*; an amount larger than can occur between the mercury and the glass in the long stem, because the surface of the diaphragm is always made larger than the total surface of the capillary tube of the stem. Expansion on heating the instrument also takes place in the direction of least resistance, viz. through an orifice in the centre of the diaphragm into the chamber *a*. The mercurial column in the stem, remaining at the lowest point to which it had contracted, thus correctly indicates the minimum temperature.

An ingenious, and at the same time simple, maximum thermometer has been devised by Mr. T. Twining. This instrument A B is a spirit thermometer, having about one-third of the way up the tube a small bulbous enlargement *c* in which at first is lodged a globule of mercury to serve as an indicator. So long as the spirit rises it flows round the mercury, but as soon as the spirit begins to descend the globule descends with it, lengthening as it does so into the form of a small cylinder *d*, the lower end of which marks on the lower scale the limit to which the spirit has descended from its highest point. Consequently, to ascertain at any time the maximum of temperature to which the instrument has been subjected, it is necessary only to add the degrees marked by the index on the lower scale to those marked on the upper scale by the extremity of the column of spirit. The thermometer is easily reset by warming it with the hand or breath until the globule of mercury rises into the little bulb; it is then laid flat until it attains the temperature of the air, when it is suspended vertically for observation. The advantages of this thermometer are its being used in an upright position, and its simplicity, which enables it to be made at a very low cost.

Fig. 3.



Thermonatrite. A native hydrated carbonate of soda, found as an efflorescence, and also in colourless and rectangular tabular crystals, in the steppes of Russia between the Ural and the Altai, the plains of Debreczin in Hungary, at the natron lakes of Lagunilla in Columbia, and in the Macarius desert in Lower Egypt. According to Haidinger, a saturated solution of carbonate of soda at a temperature between 80° and 100°, forms, on slow cooling, crystals of Thermonatrite, which differ in form from those of the common carbonate, and contain less water of crystallisation.

Thermophyllite. A mineral resembling Chlorite, occurring in crystals and grains in a

base which is probably amorphous Thermophyllite, at Hoponsuo in Finland.

Thermoscope (Gr. θερμός, and σκοπέω, *I view*). An instrument by which changes of temperature are indicated. The modification of the air thermometer, called by Leslie a *differential thermometer*, was claimed by Count Rumford as one of his own inventions, under the name of *thermoscope*. [THERMOMETER.]

Thermostat or **Heat Governor.** A self-acting physical apparatus for regulating temperature. A thermostat, the principle of which depends on the unequal expansion of metals by heat, was proposed by Dr. Ure for regulating the safety valves of steam engines with more certainty than the common expedients. (*Proceedings of the Royal Society* for 1830 and 1831, p. 67.)

Thermotics (Gr. θερμός, *warm*, from θέρω, akin to Lat. torreo, and Ger. dorren, Eng. *dry*). As *optics* relate to the phenomena which result from the action of *light* upon matter, so under the term *thermotics* may be included those effects which are caused by the action of *heat* upon matter.

By *heat* we understand that agent which, when communicated to the matter of our body, has the power to excite the sensation of warmth, and when communicated to the matter around us produces certain changes in the condition of bodies, through the particles of which it moves with more or less freedom. In this ability to be propagated by tangible bodies, heat differs from light, which, however, it closely resembles in many other respects.

Two views of the nature of heat were held by scientific men until recently. By some it was considered that heat was a highly attenuated and imponderable fluid, to which the name of *caloric* was given, and which could be added to or taken from substances. By others the materiality of heat was denied, these philosophers asserting in the words of Locke that what in our sensation is heat, is in the object nothing but motion. The former explanation is termed the *material theory*, and was the popular belief until ten or twenty years ago; the latter is known by the name of the *dynamical* or *mechanical theory*, and was advocated by Bacon, Locke, Rumford, Davy, and other eminent men, and is held by the philosophers of the present day. According to this hypothesis, which in its broad features has been established beyond doubt, the cause of heat is a certain vibratory motion of the ultimate particles of bodies. Accession of temperature means an increased motion; diminution of temperature, a lessened molecular disturbance.

If heat be thus a motion of the particles, we should be led to expect from what is termed the *correlation of force*, i.e. the convertibility of one force into another, that heat could be generated by ordinary mechanical motion, and that in turn work of this kind could be produced by heat. Both these facts have long been known. Savages know that dry pieces of wood rubbed together enable them to light their fires; school-boys by rubbing a metal button make it too hot to hold; mechanics find their tools become extremely heated when in active work; in all these cases the heat is not created by friction, it results from the conversion of the visible motion of the arm into an unseen molecular motion of the substance rubbed. Many familiar cases occur to everyone in which heat is produced by the partial stoppage, as in friction, or the complete stoppage, as in percussion, of the visible motion of a body. Thus, sparks fly from a knife on a grindstone, from the rails when a break is on the wheels of a train, from the collision of the shoes of a horse on a stony road, from the striking of the old-fashioned flint and steel. Warmth is produced by rubbing the hands, lucifer-matches are ignited by friction, and rifle-bullets often show signs of fusion, after their impact against the target. The converse is no less familiar, for the production of mechanical work by means of heat is seen on a grand scale in the steam engine; the heat of the burning coals being here the agent which moves a train or turns the wheels of a mill.

This mere qualitative relationship between heat and work was not enough to satisfy the minds of scientific men, especially the chemists, of the last generation. After Davy had liquefied ice by friction in vacuo, and Rumford had boiled water by machinery, many remained unconvinced by these experiments. But the second stage in the progress of scientific truth was at last reached, and the quantitative ratio between the work expended and the heat produced, and vice versâ, was firmly established by experiment. This second great advance in our knowledge is mainly due to the experimental researches assiduously conducted during the years 1842–49 by Dr. Joule, who by various mechanical devices succeeded in ascertaining the exact amount of heat resulting from the friction (in general of water) produced by a determinate mechanical force. Taking the mean of a great number of experiments, he expressed them thus: If a weight of 1 lb. be raised to a height of 772 feet, or 772 lbs. lifted one foot, as much heat will be generated by its descent and collision with the ground, as would raise one pound of water 1° Fahr.; or this amount of heat would be expended if used in the process of lifting the weight to a corresponding height. To avoid circumlocution, a pound raised one foot is called a *foot-pound*, and 772 foot-pounds is the so-called *mechanical equivalent of heat*.

Many interesting conclusions have been drawn from this equivalence. SHOOTING STARS are probably meteorites rendered incandescent by the friction which they encounter on entering our atmosphere; this friction, increasing as they approach the earth towards which they are drawn, finally dissipates them as vapour, sparing us from the serious consequences which would otherwise result from collision. The amount of heat which would be generated by the stoppage of the earth's orbital motion has

been calculated, and found to be equal to the combustion of 14 globes of coal equal to the earth in size. The falling of the earth from its present position into the sun would develope heat equal to the combustion of 5,600 worlds of coal, simply from the destruction of its acquired motion. This heat would be sufficient for the solar emission for a period of 95 years; whilst if the planet Jupiter were to fall into the sun, the heat generated would furnish a supply of solar heat enough to last for 32,240 years. The heat and light of the sun have therefore been reasonably attributed to the continual falling into its mass of cold asteroids circulating around it. Astonishing as these conceptions appear, they are not untrue or exaggerated, for they are based upon a great natural law, discovered by the strictes texperimental enquiry.

A force is known only by its effects on matter, which it thus renders cognisant to our senses. One of the most evident of the actions of the force of heat on matter, is its power of dilating the substances to which it is communicated. After thus causing an *expansion* of the substance, i.e. increasing its volume, the further application of heat produces a change in the state of the body, if a solid rendering it liquid, and if liquid rendering it gaseous; a process accompanied, in general, by a considerable enlargement of bulk. For equal increments of heat, solids expand less than liquids, and liquids less than gases.

The *expansion of solids* is so small that it requires the aid of multiplying apparatus to render it sensible. Many of the instruments constructed for this purpose can also be used for measuring high temperatures, and hence they bear the general name of *pyrometers*, which have already been fully described. [PYROMETER.] All solids do not expand equally for equal additions of heat; the metals, as a rule, expanding most. The *coefficient of expansion* of a body is the amount of dilatation which it undergoes when heated one degree. If, as is usual, only the length of the substance be measured, it is called the *linear coefficient*; the total or cubical expansion can be obtained by multiplying this number by three. In the following table are given the linear coefficients of expansion for 1° C. of several well-known substances:—

Expansion of Solids.

Glass	0·0000086
Platinum	0·0000088
Cast iron	0·0000112
Wrought iron	0·0000122
Gold	0·0000146
Copper	0·0000172
Brass	0·0000188
Silver	0·0000191
Tin	0·0000217
Lead	0·0000286
Zinc	0·0000294

Dr. Matthiessen has of late determined the expansion of metals and alloys by weighing them in water kept at different temperatures, and has proved that the coefficients of expansion of metals are not quite regular even between 0° and 100° C., and that the coefficient of expansion of an alloy is equal to the mean of the coefficients of expansion of the volumes of the metal composing it.

Owing to the nearly equal expansibility of platinum and glass, chemists are able to fuse platinum wires into glass tubes, and thus readily construct an apparatus which bears changes of temperature without fracture, a result which could not be obtained if the coefficients of the two substances were different. The difference in the expansion of certain metals has been practically applied in the construction of compensating pendulums. Of these there are various kinds, but the object in each is to neutralise the increase of length in the pendulum rod, resulting from an augmented temperature, by lifting to a corresponding extent the centre of gravity of the pendulum. This is obtained in the gridiron pendulum by the expansion of alternate steel and brass bars, of different lengths, which support the bob. In the mercury pendulum, the bob, instead of being solid, consists of a glass cylinder containing mercury: a rise of temperature causes the pendulum rod to lengthen, thus depressing the bob, but at the same time the mercury expands; and as it can only rise, it lifts the centre of gravity through an equal space, mercury being more expansible than the steel of the pendulum rod. The compensation balance in watches also depends on the unequal expansion of different metals, which are so juxtaposed that opposite effects shall be produced by their dilatation. The force exerted by a body in expanding or contracting is enormous, and has been made use of in the arts; the tires of wheels are put on, and rivets are used whilst red-hot, so that on the cooling of both the contraction which ensues closely binds the parts together: the bulging walls of buildings have even been straightened by the contraction of iron bars stretched from wall to wall and tightly screwed up when red-hot.

The *expansion of liquids* can be determined by enclosing them within a graduated vessel, and noting the increase in bulk for a given rise in temperature. Such an instrument is the ordinary mercurial or alcohol thermometer, which registers differences in temperature by the dilatation or contraction of the enclosed liquid. [THERMOMETER.] It is evident, however, that this measurement is less than the real dilatation, for whilst the liquid expands the containing vessel also enlarges in bulk; hence the rise of the mercury in a thermometer is due to the difference in expansion between the liquid and its glass envelope. The absolute expansion of a liquid can be found by adding to this, which is termed the *apparent expansion*, the expansion of the material of the vessel. Dulong and Petit, and more lately Regnault, have adopted another means for determining the absolute expansion of mercury, which was found to be practically uniform between the freezing and boiling points of water. This, however, is not the case with many other liquids, the rate of expansion generally increasing as the temperature rises.

The most volatile bodies are, as a rule, the most expansible; the extremely volatile liquids which result from the condensation of gases enlarge in bulk even more rapidly than when in the gaseous state. Thus, liquid carbonic acid has been found, with the same rise in temperature, to expand four times as much as air.

In certain states the behaviour of water and one or two substances is a remarkable exception to the general law, that bodies expand when heated, and contract when cooled. If water at the ordinary temperature be cooled down, it contracts like other liquids until it reaches a temperature of 39° Fahr.; it then begins to expand, till it reaches the freezing point, just before which it occupies as large a bulk as it did at 48°. The smallest bulk which water can be made to occupy is at 39°, and hence this point is called the maximum density of water. Between 32° and 39° water will therefore contract when heated, and expand when cooled. This anomaly in the case of water is a fact of the greatest importance. It is owing to this that the great bulk of the water of rivers and lakes is protected from a freezing temperature, which would be fatal to the animals contained in them. After the whole body of the water has reached a temperature of 39°, further cold lightens the superficial portions, which thus remain on the surface; and after a time this fact is rendered evident by a floating cover of ice.

The first reliable experiments on the *expansion of gases* by heat were made by Gay-Lussac, who arrived at a law that all gases and vapours expand alike for equal increments of heat. In passing from the freezing to the boiling point of water they increase in bulk more than one-third, or augment $\frac{1}{490}$ of their volume for every degree Fahrenheit. More recently the elaborate researches of Regnault have proved that Gay-Lussac's law is true only for the permanent gases, the coefficient of expansion of which is 0·00366, or $\frac{1}{273}$ of their volume, for every degree Centigrade, the condensible gases having a slightly greater coefficient than this. The large increment in bulk which gases undergo when heated has been made use of in many ways. The air thermometer [DIFFERENTIAL THERMOMETER] depends on this fact, and from the delicacy of its indications was constantly used in experiments on radiant heat, until replaced by the thermopile. The rise of fire balloons and of smoke in chimneys, winds and air currents, and the ventilation of rooms, depend on the greater bulk of heated air.

A point of great importance is connected with the expansion of gases by heat. When a gas is heated and allowed to expand freely under ordinary atmospheric pressure, its coefficient of expansion is nearly the same as that found by keeping the volume of the gas constant, and noting the additional pressure necessary to overcome the increased elasticity of the gas, which is augmented in proportion to the temperature. But the amount of heat required to raise the temperature of the gas a certain amount in the former case, when the *pressure* is kept constant, is more than that required in the latter, when the *volume* is kept constant. The exact proportion in the two cases is as 1 : 1·421. The explanation of this difference is to be found in the fact, that where the gas is free to expand under constant pressure, it lifts a weight, and therefore does an amount of work which is not accomplished when it is heated under constant volume. The additional heat absorbed is used solely to lift the weight; and this precise amount, if the pressure be unaltered, is again evolved when the gas contracts to its original volume. As, therefore, the excess of heat is employed in nothing but mechanical labour, it expresses the relationship between heat and work; and accordingly from this ratio it would be possible to deduce theoretically the mechanical value or equivalent of heat. The importance of this fact was clearly seen by a German philosopher named Mayer, who made a calculation of the mechanical equivalent shortly before Dr. Joule arrived at his experimental results. When error is avoided, the equivalent found in the two cases is practically the same.

If we regard heat as a vibratory motion of the particles of bodies, we arrive at a simple explanation of the effects of heat in causing expansion and change of state. The addition of heat causes more rapid and wider molecular vibration; for the particles of the coldest substances are not deprived of the motion of heat. This increased range of motion increases the distance between the particles, and expansion of the whole substance ensues. But as the particles recede from each other, the force of cohesion which holds them together becomes lessened according to known laws; the substance thus passes from the solid condition, in which cohesion is strongest, to the liquid state, in which it is far less. By further heating, the cohesion of the liquid can be entirely overcome, and the particles, now without any bond of union, fly asunder in the vaporous or gaseous form. When this occurs, ebullition or boiling of the liquid begins: with water the boiling point is 212° Fahr. when the barometer stands at 30 inches. Ebullition takes place when the heat has so increased the elasticity of the particles of the liquid, that the tension of the vapour which is formed is equal to the atmospheric pressure: the greater the pressure, therefore, the higher the boiling point, or vice versâ. When the vessel is heated at the bottom, the weight of the column of the liquid has to be added to the pressure of the air, so that the lower portion of water heated in long tubes or in large masses rises considerably above 212°, and the boiling is irregular and explosive.

While a substance remains in one state of aggregation, the heat imparted to it raises its temperature, as is evident by the sense of touch or by the rise of a thermometer. But in passing from the solid to the liquid, or from the liquid to the vaporous condition, the heat

absorbed by the substance during this time is insensible to the touch or to the thermometer. If, for example, a block of ice be heated, a thermometer fixed within it rises until it reaches a temperature of 0° C. or 32° Fahr.; it then ceases to rise until the whole of the ice has been liquefied, after which it begins again to move and continues rising until it marks a temperature of 100° C. or 212° Fahr. Steam is now produced, and if the water be in an open vessel, the further application of heat causes no further change in the thermometer. When the first experimentalists saw that a large addition of heat to ice at 32°, or water at 212°, caused no change in the thermometer, they accounted for the heat that had disappeared by saying it had somehow become hidden or latent, and thus arose the term of *latent heat*. This unsatisfactory explanation has been removed by the dynamical theory, which assigns the heat that has become insensible to the performance of work in shifting the relative positions of the atoms. Heat in the so-called latent state is, in fact, heat consumed in mechanical motion, just as in a steam engine heat is consumed in causing a crane to lift a weight. And as when the lifted weight is allowed to fall, it generates in its fall the exact amount of heat actually spent in raising it, so the precise amount of heat absorbed by a body in order to change its state of aggregation is reproduced when it passes back to its original condition.

The heat necessary to liquefy a solid is called the *latent heat of liquidity* or *latent heat of fusion*, and the heat employed in changing a liquid into vapour is called the *latent heat of vaporisation*. In the case of water, the amount of heat necessary to cause ice at 32° to become water at 32° would raise the same weight of water 143° Fahr.; whilst to convert water into steam of the same temperature, 967° Fahr. are required. The former number is called the *latent heat of water*, the latter the *latent heat of steam*. But these numbers are not the same for all bodies; each substance has its own latent heat. The different amounts of heat required to liquefy and vaporise a few of the more important bodies are here given. The figures are taken from Miller's *Chemical Physics*, and express the temperature that an equal weight of water would be raised by the passage of each of the bodies enumerated, from the liquid to the solid, or from the vaporous to the liquid state.

Latent Heat of Liquefaction.

	F.		F.
Water	143°	Sulphur	17°
Zinc	51	Lead	10
Silver	38	Phosphorus	9
Tin	26	Mercury	5
Bismuth	23		

Latent Heat of Vaporisation.

	F.		F.
Water	967°	Bisulphide of carbon	156°
Alcohol	375	Oil of lemons	126
Acetic acid	183	Oil of turpentine	124
Ether	163	Iodine	43

When a solid is reduced to the liquid state by solution, heat is in like manner always absorbed, unless a chemical combination of the solid and liquid occur. The solution of salt or sugar in water thus chills the liquid. FREEZING MIXTURES can even be formed by the extreme cold which attends the liquefaction of many soluble salts. On the other hand, heat is evolved during solidification, so that in winter, when masses of water freeze, the severity of the cold is mitigated. The chilling caused by vaporisation explains many familiar facts. By the evaporation of eau-de-cologne or ether, a forehead moistened with the liquid is cooled; on the same principle water can be frozen and ice made in large quantities. It is also from the evaporation of the water which has percolated to the outside that porous earthenware vessels filled with water cool objects placed within them.

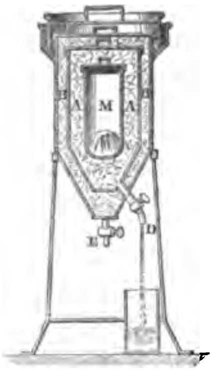
Having seen that heat when imparted to a body can be applied in two ways, either in raising its temperature or in changing its state of aggregation, and having ascertained that different solids and liquids require different quantities of heat to alter their condition, the question now arises, Do all substances whilst in one condition rise equally in temperature for equal increments of heat? They do not; and this difference, which is a special and important characteristic of all bodies, used to be termed the *capacity for heat*, but is now generally spoken of as the *specific heat* of a substance. By this term is meant the quantity of heat required to raise the temperature of any substance 1°, compared with that required to raise an equal weight of water 1°.

As different amounts of heat are expended in raising the temperature of different bodies to the same point, if various substances be taken at the same temperature they will not all contain the same quantity of heat; nor will they, if cooled down, yield equal amounts. Accordingly, when two liquids at different temperatures are mixed together, the resulting temperature will not be the mean of the two, if the liquids are of different specific heats. A pound of ice-cold water mixed with a pound of boiling water gives two pounds at the mean temperature, viz. $(32° + 212°) \div 2 = 122°$ (if ice at 32° be taken instead of water, the latent heat of water must, of course, be first subtracted from the hot water); but if equal weights of mercury at 32° and water at 212° be mixed, the resultant temperature will be about 206°; i. e. the water has lost only 6°, whilst the mercury has gained 174°. The specific heat of mercury is therefore about 30 times less than the specific heat of water.

Various means have been employed for determining the specific heat of a body; these, however, can be reduced to three different principles. The earliest and most liable to experimental error is founded on the melting of ice, and was used by Black, Lavoisier, and Laplace. This method consists in heating a given weight of the body up to some fixed temperature, say 212°, then plunging it in dry ice, and subsequently determining the amount of ice

which it melts in cooling down to 32°. The apparatus by which this is usually accomplished is known under the name of the *ice calorimeter*. A section of this instrument is annexed; the drawing is taken from Ganot's excellent treatise on elementary physics. The body the specific heat of which is to be determined, after having been weighed and heated for some time in an oil or water bath, is placed in the central compartment M. A lid is quickly placed over it and covered with pounded ice, which already fills the surrounding vessel A; over this again another lid is placed and covered with ice, which the outer concentric vessel B also contains; finally a double lid covers the whole. The vessel M is thin and a good conductor, so that the ice in A is quickly melted by the hot body M. The water thus produced flows out by the stopcock D, and is carefully collected and weighed. The ice in the outer vessel B cuts off the influence of the surrounding atmosphere, the water from any liquefaction that may occur escaping by the stopcock E. The latent heat of water being known, the specific heat of the substance can readily be calculated from the quantity of water which has been melted from the ice in A. Black used in his experiments a simple block of ice, in which a cavity was made to contain the heated body, and over which an ice cover was laid. After a time both substance and cavity were wiped dry with a cloth, the weight of which before and after was determined. This forms a ready and simple way of roughly estimating the specific heat of various bodies.

Fig. 1.



The second method of determining the specific heat of a substance is to note, under similar circumstances, the *rate of cooling* of different bodies the weight and temperature of which are equal. The last method is that of *mixtures*, an example of which (mercury and water) has already been given. In the case of a solid body determined by this method, the substance is weighed, raised to a known temperature, and then plunged in a known weight of water; from the rise in temperature of the water the specific heat of the solid is calculated. This method has been adopted by Regnault in a series of exhaustive and most refined experiments on the specific heats of solids, liquids, and gases. In examining liquids it is necessary to enclose them in a little vessel; and gases are caused to pass through a spiral tube surrounded with water, the alteration in temperature of which is observed. The following table gives some of Regnault's results on the specific heat of different solids, liquids, and gases, compared with an equal weight of water taken as unity.

Specific Heat of Solids.

Lithium	0·941	Zinc	0·095
Ice	0·474	Copper	0·095
Sodium	0·293	Brass	0·094
Wood charcoal	0·241	Silver	0·057
Sulphur	0·203	Tin	0·056
Glass	0·198	Gold	0·032
Diamond	0·147	Platinum	0·032
Iron	0·114	Lead	0·031

Specific Heat of Liquids.

Water	1·000	Turpentine	0·426
Alcohol	0·637	Bisulphide of carbon	0·235
Ether	0·528	Mercury	0·033
Benzol	0·436		

Specific Heat of Gases.

Hydrogen	3·409	Nitrogen	0·244
Marsh gas	0·593	Air	0·237
Ammonia	0·508	Oxygen	0·218
Aqueous vapour	0·481	Carbonic acid	0·216
Olefiant gas	0·404	Chlorine	0·121
Carbonic oxide	0·245		

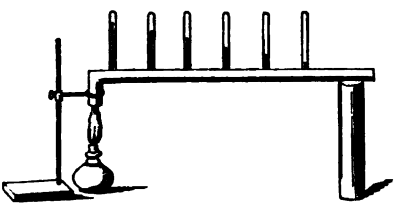
Of all solids and liquids, water has the highest specific heat; this, which is one among the many singular and wonderful properties of water, is an important fact, and one of the highest value, especially in the influence which large masses of water must exert in moderating extremes of climate. A substance in the liquid state has a higher specific heat than the same body when solid, but it is lower in the gaseous than in the liquid condition. Temperature increases the specific heat of a substance: for example, the specific heat of water at 32° is 1·000, whilst at 212° it is 1·013. Dulong and Petit discovered a relationship between the specific heat of an element and its weight, and established a law, which bears their name, that the specific heat of an elementary body is *inversely* as its atomic weight; consequently the product of the specific heat of an element into its atomic weight gives, with but slight variations, a constant number or a multiple of that number. This product is known by the name of the *atomic heat* of a body, or the quantity of heat necessary to raise the temperature of the same number of atoms one degree. As this is a nearly constant quantity, 'all elementary atoms, great or small, light or heavy, when at the same temperature, must possess the same amount of the energy called heat, the lighter atoms making good by velocity what they want in mass.' Regnault, in his researches, has confirmed Dulong and Petit's law, and extended it to compound bodies.

Thus far the effects of heat upon different bodies have been examined: it now remains only to state the manner in which heat is propagated, a process constantly taking place in order to restore or preserve that equilibrium of temperature spoken of under the article Radiation. This propagation of heat is carried on in three ways. If a solid body be heated at one end, the motion of heat thus imparted is communicated from one molecule of the body to that next adjacent, and this to the next, and so on, until the heat, passing from

particle to particle, has slowly reached the utmost limits of the solid, the intensity rapidly diminishing as the distance from the heated point increases. This process of transmission is termed *conduction*. Amongst liquids and gases, the transfer of heat is accomplished not by a molecular movement of this kind, but by the motion of sensible masses from place to place. When a liquid or gaseous column is heated at the bottom, the part warmed expands, and becomes lighter than the mass above; it consequently rises, and is replaced by colder and denser portions: ascending hot currents and descending cold currents are thus produced, and by a circulation of this kind the whole mass is heated. Distribution of heat by this means is called *convection*. Finally, the heat of a warm body is propagated, not only by conduction to contiguous particles, or by convection through limited masses, but is carried to an unlimited distance by radiation. It is here that heat so closely resembles light, being propagated in the same manner and obeying the same laws. [RADIANT HEAT.]

Returning to the conduction of heat, we find that all bodies do not possess this power equally. Some, like the metals, which also differ among themselves, can transmit the molecular motion of heat with considerable ease; these are therefore termed *good conductors*. Others, like glass, wood, and all organic substances, impede this motion, and are called *bad conductors*. Liquids, and more especially gases, communicate this motion among their particles so slowly that they may practically be regarded as non-conductors. Ingenhausz, Despretz, Wiedemann and Franz, and Calvert and Johnson, have determined the conductivity of various substances. The means employed by Despretz is represented essentially in fig. 2. In a bar of the substance to be tried, holes are drilled at equal intervals; in these cavities mercury is poured, and a delicate thermometer is placed in each of them. The bar is heated at one end, the thermometers slowly rise one after the other, until, after a sufficient time has elapsed, they cease to move, indicating a fixed temperature, which is less the farther they are removed

Fig. 2.



from the source of heat. The worse the conductor, the greater the difference between any two successive thermometers. A more recent and complete investigation has been made by Wiedemann and Franz, who employed the same method, substituting, however, thermo-electric couples for the thermometers. From the results of these experimenters the following table is derived; the best conductor, silver, being represented by 100, copper will be 74.

Conductivity of Solids.

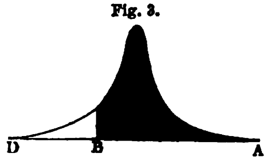
Silver	100	Iron	12
Copper	74	Lead	9
Gold	53	Platinum	8
Brass	24	German silver	6
Tin	15	Bismuth	2

It has been found that the order of conductivity in this table is also the order in which the same bodies conduct electricity: a remarkable and interesting relationship is thus established between these two forces. Bodies which are not homogeneous do not conduct heat equally in every direction; this was discovered and shown to be the case with crystals by De Senarmont, and with wood by De la Rive and De Candolle, a fact confirmed and extended by Tyndall.

It is owing to the different conducting power of bodies, that various substances at the same temperature feel unequally hot or cold. The use of kettle-holders and wooden handles is to protect the hand from the heated metal by the interposition of a bad conductor. For the same reason our clothes keep us warm by preventing the loss of bodily heat; the worse the conductor, therefore, the warmer the garment. Engineers also use this principle when they surround the boilers of steam engines with a jacket of some bad conducting substance. The cracking of glasses and jugs by suddenly pouring hot water within them, whilst metal vessels are not thus broken, is another result flowing from differences in conductivity.

Considerable light has been thrown upon the molecular changes which a body undergoes when being heated, by the investigations of Draper in America. This philosopher watched through a prism the changes in the radiation emitted from a body gradually raised from an obscure to a white heat. When any cool body, a poker, for example, is heated in the fire, the rays first emitted by it are entirely invisible or obscure. Beginning with

Fig. 3.



the emission of rays of low refrangibility, represented by the curve at the right-hand end of the diagram (A, fig. 3), the radiation from the poker, as it is more highly heated, gradually increases in intensity, until at last (B) it becomes incandescent; retaining all the rays previously emitted, it now sends forth in addition waves of red light, to which presently are added orange, then yellow, then green, then blue, indigo, and violet, and when all the colours of the spectrum are present, it glows

with a white heat, giving the spectrum of thermal intensity, A B D. It is probable that after this point has been reached, if the substance be sufficiently refractory to allow of still increased heating, it will give out with increasing intensity the rays beyond the violet, until the glowing body can rapidly act in forming chemical combinations, processes which require rays of the highest refrangibility, the so-called actinic or ultra-violet rays. These are the changes which occur in heated solids or liquids; but with gases the case is different, for no gas or vapour, however much heated, has yet been found to emit luminous rays.

For further information, and a lucid application of the dynamical theory to the various phenomena of heat, the reader may consult Tyndall's excellent treatise on *Heat as a Mode of Motion*, and Stewart's concise manual on *Heat*.

Theseus (Gr. Θησεύς). The rationalistic process by which Herodotus (i. 1–5) extracted a prosaic and perfectly plausible narrative out of the impossible myths of Io, MEDEIA, and HELEN, enabled Thucydides (ii. 15) to frame for the age of the mythical Theseus a political history which may certainly be true, but for which we have not the faintest evidence. According to the great Athenian historian, Theseus was the far-sighted statesman who, seeing the evils of isolation, deprived the Attic demi of their absolute autonomy, and bound them together in a confederacy in which Athens became the seat of a single commonwealth. Over this state he ruled not as a despot, but as a constitutional sovereign, strictly confining himself to his definite functions.

This plausible fiction has been extracted from the stories of the older mythographers, who spoke not of a sagacious political leader consulting the best interests of his people, but of a son of POSEIDON (or Ægeus, king of Athens) and of Æthra (*the pure air*), who grew up in the house of Pittheus, king of Trœzen, under the care of his mother, who told him that a great work lay before him so soon as he could lift the stone beneath which lay his father's sword and sandals. Thus, in due time gaining possession of the invincible weapon, as Sigmund, in the tale of SIGURDR, obtained the good sword Gram, Theseus started on that career of conquest the incidents of which present the closest parallel to those of Perseus, Bellerophon, Meleagros, Œdipus, and, most of all, of Heracles, of whom he is in every respect the counterpart. Like him, he is a destroyer of noxious beasts, the avenger of the oppressed, and the terror of evil-doers. Having smitten PROCRUSTES and a horde of lawless marauders, he reaches Athens, where, according to one version, Medeia recognised and sought to poison him. With the sword as the token of his birth, he appeared before Ægeus, who acknowledged him as his heir. In the chase of the Marathonian bull which followed not long after, Androgeos, son of MINOS, met his death; and the levy of the tribute children was imposed on the Athenians by the Cretan king. Voluntarily offering himself to join the doomed band, Theseus went to Crete, where ARIADNE gave him a sword wherewith to slay the MINOTAUR, and a clue by which he might extricate himself from the labyrinth. On his homeward voyage Ariadne accompanied him, but being deserted by him in Naxos, she became afterwards the bride of DIONYSUS. As the ship of Theseus drew near to the Peiræeus, he forgot to hoist the white sail which he had promised to raise as the signal of safety, and thus, like Perseus and Œdipus, Theseus becomes the cause of his father's death. Among the later exploits of Theseus was his war with the AMAZONS, who are said to have invaded Attica, and to have been defeated by him in Athens itself. He is also one of the heroes in the Argonautic voyage [MYSTERIES], in the Calydonian hunt, and in the war against Thebes. Aided by Peirithous and the Lapithæ, he fought against the CENTAURS, and with the help of the former he carried away Helen from Sparta. In return for this kindness, he took part in the attempt of Peirithous to steal PERSEPHONE from Hades, and when Peirithous had fallen, he himself underwent a captivity from which he was at length delivered by Heracles. But his life, like that of Perseus and Œdipus, closes in gloom. Enemies plot against him, and he withdraws to Skyros, where he is treacherously slain.

According to some traditions, Theseus not only carried away Helen, but became by her the father of Iphigeneia, whom Clytæmnestra brought up only as her foster child, and who, according to the Æschylean version, was sacrificed by Agamemnon at Aulis to avert the wrath of Artemis. In other tales, a meaner victim is substituted in her place, and Iphigeneia becomes a priestess of Artemis in Tauris, famed for its human sacrifices; in others, again, Iphigeneia is identified with Artemis herself. Athenian legends represented her as carrying the statue of Artemis to Brauron near Marathon, where she is said to have died. As a daughter of Theseus, she was connected with the heroic families of Attica, where human sacrifices were offered to her, if we may draw this inference from the custom, in historical days, of shedding some human blood in the worship instituted in honour of Orestes.

Thus, like Phœbus, Apollo, and Perseus, like Heracles, Achilleus, Odysseus, and Bellerophon, Theseus carries an invincible weapon, which none else has the strength to wield; like them and other solar heroes, he is a slayer of monsters, which answer to Python and Fafnir, to Belleros and the Sphinx, to the Chimæra and the Libyan dragon. Like Apollo and Heracles he undergoes captivity; and again, like Œdipus and Perseus, he becomes unwittingly the slayer of his father.

Thus the great dynastic legend of Athens exhibits the closest parallelism to the dynastic legends of Thebes and Argos. They are all, in short, versions of the same story.

differing only in names and in points of petty detail. Of this close agreement, the Athenians, Thebans, and Argives were doubtless profoundly unconscious; and their unconsciousness is the strongest evidence that these myths sprang up spontaneously on the soil of each country from phrases which denoted originally sights and sounds in the outward world. The story of Theseus is the story not only of other Hellenic heroes, but of Rustem, Feridoun, and Sigurdr.

Thesis (Gr. θέσις, *a position*). In a general sense, this word is applied to denote any proposition, affirmative or negative, which is laid down or advanced to be supported by argument; but it is more particularly applied to those questions which are propounded in most of the Scotch and the continental universities to the students previously to their obtaining a degree.

THESIS. In Music, the depression of the hand in marking or beating time.

Thesmophoria (Gr. θεσμοφόρια). A festival in honour of Demeter, surnamed the *lawgiver* (θεσμοφόρος). It was celebrated by many cities of Greece, but with most ceremony by the Athenians. [TRIPTOLEMUS.]

Thesmothetæ. [ARCHON.]

Thespesia (Gr. θεσπέσιος, *marvellous*). A small genus of *Malvaceæ*, consisting of entire-leaved tropical trees. *T. populnea*, the best-known species, is very common on the sea-shores of most eastern tropical countries, and also in Western Africa, the West Indies, South America, and the Pacific Islands. It grows to a height of forty or fifty feet; and from its dense head of foliage, it is in some countries called the Umbrella-tree. Several parts of the tree are applied to useful purposes. The inner bark of the young branches yields a tough fibre, fit for cordage, and used at Demerara for making coffee-bags, and the finer pieces of it for cigar envelopes. The wood is considered almost indestructible under water, and is therefore used for boat-building; its hardness and durability render it valuable for cabinet-making and building purposes, while in Ceylon it is employed for gun-stocks. The flower-buds and unripe fruits yield a viscid yellow juice, useful as a dye, and a thick deep red-coloured oil is expressed from the seeds.

Thespian Art. The art of tragedy or tragic acting is sometimes so termed, from Thespis, an Athenian, who lived in the first half of the sixth century before Christ, and introduced the first rudiments of a tragic stage. [DRAMA.]

Theta. The unlucky letter of the Greek alphabet, from its being the first letter of θάνατος, *death*. Hence the verse—

O multum ante alias infelix litera Theta.

Thetes (Gr. θῆτες). In ancient Attica, originally freemen who worked for hire. Under the constitution of Solon they formed the lowest class of free citizens, who contributed nothing to the support of the state. They served generally as light-armed soldiers, but sometimes also as regular infantry upon an emergency. (Boeckh, *Public Economy of Athens*, ii. 258; Grote, *History of Greece*, part ii. ch. xi.)

Thetis. In Greek Mythology, one of the Nereids, and wife of Peleus, king of Thessaly, by whom she became the mother of Achilles. [HOMERIC POEMS; ILIAD; MYRMIDONS; ODYSSEY.] It was at the marriage feast of Peleus and Thetis that ERIS threw on the table the golden apple, for which HERA, APHRODITE, and Athênê [MINERVA] appeared as claimants before PARIS.

Thick Strakes. In Shipbuilding, strakes of planking thicker than those used elsewhere. They are bolted on over the points of junction of the several pieces which compose the ribs or timbers.

Thicket (from *thick*). In Forestry, trees or shrubs crowded together in such a manner as to form a mass not easily penetrated by men or cattle.

Thickstuff. In Shipbuilding, this word denotes all plank above four inches in thickness.

Thierschite. A native oxalate of lime, forming a thin incrustation on the marble of the Parthenon at Athens.

Thieves' Vinegar. This useless preparation, which is also called *Marseilles vinegar*, and *Vinaigre des quatre voleurs*, is made by digesting rosemary tops, sage leaves, lavender flowers, and cloves, in vinegar: it was once regarded as an effective antidote against the plague and other contagious diseases.

Thin Out. Geologists say that strata *thin out* when they gradually diminish in thickness and disappear.

Thing or **Ting.** In the ancient Swedish (Suio-Gothic) and cognate languages, a judicial or legislative assembly. [ECCLESIA; PARLIAMENT.] The origin of the word is obscure. The *thingvalla* in Iceland was a spot in the southern part of the island where the *althing*, or general parliament, was accustomed in the middle ages to meet. (Ihre, *Glossarium Suio-Gothicum.*)

Thinning (from thin, Lat. tenuis). In Arboriculture, reducing the number of plants or trees which have been sown or planted, in order that those which are left may attain a more mature growth. Natural woods are also thinned for the same purpose. The operation ought to be commenced as soon as the extreme leaves or branches are nearly touching one another, and continue till the plants have attained their full growth, or the required dimensions or age. On no account should the branches of any one tree in a plantation be allowed to touch the branches of any other tree; because in that case the foliage is deprived of its due proportion of sun, air, and rain, and the tree is drawn up in height at the expense of its thickness and vigour to resist storms; while the timber or fruit produced will be diminished both in quantity and quality. There is no department of planting less understood than the subject of sheltering young plantations; and it may with truth be

said that in by far the greater number of cases nothing is ultimately gained by drawing up trees in masses, and afterwards thinning them out. The trees left being unprepared both by their bark and roots for the new atmospherical circumstances in which they are placed, receive a greater check than if they had been originally planted so thin as at no period of their growth to touch one another. The same rules apply to agricultural and horticultural crops.

Thiosaurite. A white or greyish variety of Anorthite found at the Plain of Thiorsa in Iceland.

Third (Lat. tertius, Ger. dritte). An interval in the musical scale, which may be either major or minor, the former containing four, the latter three semitones.

Third Order. In Ecclesiastical History, most of the chief religious orders have or had bodies of secular associates, not bound by vows, but conforming to a certain extent to the general designs of the order; a custom which, in the opinion of some, originated about A.D. 1476, when Sixtus IV. gave permission to the Carmelites to attach such persons to their body. In course of time the third order contained a mixture of secular and religious persons. [ORDERS, RELIGIOUS.]

Thirst (Ger. durst). The sensation of a desire to drink, consisting in a sense of dryness and heat of the mouth, sometimes extending along the œsophagus to the stomach. In cases of intense thirst, unrelieved by swallowing fluid, the posterior fauces become red, and the usual mucous secretion, as well as the saliva, becomes thick and viscid. A vague inquietude, troubled mind, and quick pulse ensue, and respiration becomes laborious. Some people soon suffer from thirst, and are in the habit of drinking to an excessive extent, while others hardly ever experience the sensation. Thirst is a common symptom of febrile and other diseases, such as diabetes both in the mellitic and in the insipid form. Excessive exercise or perspiration are common causes of thirst, in which case the sensation seems merely to announce the deficiency of water in the system. Habitual thirst is often acquired by indulgence in drinking, especially among labourers and others who take large quantities of beer, and who at length can scarcely exist without unnecessary and hurtful quantities of that or similar beverages. The thirst induced by exercise in warm weather is in ordinary cases most effectually relieved by milk and water, or tea.

Thirty Years' War. In History, properly a series of wars carried on between the Protestant and Roman Catholic leagues in Germany, in the first half of the seventeenth century. The house of Austria was throughout at the head of the latter party. The Protestant princes of Germany were assisted by various foreign powers; in the earlier part of the war by Denmark and Sweden, and afterwards by France. It is considered to have commenced with the insurrection of the Bohemians in 1618, and it ended with the peace of Westphalia in 1648. The history (incomplete) of this war, by Schiller, is rather a spirited historical essay than an accurate narrative.

Thirty-twos. In Printing, a sheet of paper which when printed folds up into thirty-two leaves or sixty-four pages. The book is called a 32mo.

Thistle. A general name for various plants, mostly belonging to the Composite family, though not confined to it. It is the popular name for the plants referred to the genus *Carduus*, one species of which, *C. lanceolatus*, is the plant which is most generally regarded as the Scottish national emblem, though a distinct plant, the *Onopordon Acanthum*, is sometimes so considered. The Holy or Milk Thistle is *Silybum marianum*; the Blessed Thistle is *Cnicus benedictus*; the Sow Thistle is the name of the genus *Sonchus*. A totally different genus of plants, of the Cactus family, viz. *Cereus*, is called Torch Thistle, and another member of the same family, *Melocactus*, is the Melon Thistle. Thistles are principally to be regarded as weeds.

Thistle of Saint Andrew. A Scottish order of knighthood, said to be of great antiquity, but revived by James V. in 1540; again by James II. of England, VII. of Scotland, in 1687; and a third time in 1703, by Queen Anne, who increased the number of knights to twelve, and placed the order on a permanent footing. The thistle, as is well known, is the national emblem of Scotland; the appropriate national motto, which is also the motto of the order, being, 'Nemo me impune lacesset' (*No one shall provoke me with impunity*).

Thitsee. *Melanorrhœa usitatissima*, the Varnish-tree of Burmah.

Thmei. An Egyptian goddess, frequently represented in Egyptian sculptures in the hands of the kings. The Hebrew Thummim (the Urim and Thummim, Exod. xxxix. 8, 10) is the plural or dual of the same word. (Wilkinson's *Manners and Customs of the Ancient Egyptians*, vol. v. p. 58.)

Tholes (A.-Sax. thol). The pins forming the *rowlocks* in the gunwale of a boat. If there be two to each rowlock, the oar is worked between them; if but one, the oar is fastened to it by a strap, or the thole passes through a hole in the oar.

Tholus (Gr. θόλος). In Architecture, a building of a circular form. The word is used by Vitruvius to signify the roof of a circular building. It was also employed to denote the laconicum of a bath, which was circular in form.

Thomæans or **Thomites.** In Ecclesiastical History, a name given in Europe to the ancient church of Christians established on the Malabar coast of India, and said to have been originally founded by St. Thomas. The language used by them in their sacred rites, when they were first discovered by Europeans, was the Chaldee or Syriac. The Portuguese have effected a partial conversion of them to the Roman Catholic Church.

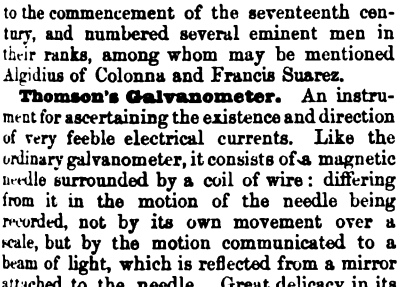
Thomäite. A prismatic form of carbonate of iron from the Siebengebirge, named after Professor Thomä.

Thomists. The followers of Thomas Aquinas, the Angelic Doctor, one of the most distinguished of the schoolmen of the thirteenth century. They differed from the rival sects of Scotists chiefly in the milder form under which they adopted the doctrines of realism. The Scotists regarded the universal as objectively and independently real; the Thomists sought rather to ground the objective in a spiritual or rational principle, in some degree approximating to the Platonic doctrine of ideas. The Thomists continued as a sect to the commencement of the seventeenth century, and numbered several eminent men in their ranks, among whom may be mentioned Ægidius of Colonna and Francis Suarez.

Thomson's Galvanometer. An instrument for ascertaining the existence and direction of very feeble electrical currents. Like the ordinary galvanometer, it consists of a magnetic needle surrounded by a coil of wire: differing from it in the motion of the needle being recorded, not by its own movement over a scale, but by the motion communicated to a beam of light, which is reflected from a mirror attached to the needle. Great delicacy in its indications can thus be attained. Instruments of this kind are in general termed *reflecting galvanometers*, but the one invented by Sir William Thomson has some special peculiarities which will be briefly described.

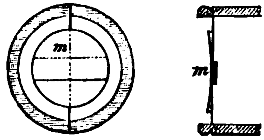
The instrument is represented at G M *b* in the accompanying drawing, for which we are indebted to Mr. Becker, of the firm of Messrs. Elliot Brothers, the makers of these instruments.

Fig. 1.



Several hundred coils of fine copper wire, made into a bobbin *b*, surround the circular aperture seen in the centre of the instrument. Within this aperture is suspended a tiny magnet, to which is attached an extremely light circular mirror *m* (fig. 2), about the size of a threepenny-piece. The light from a paraffin lamp, after passing through a slit in the lower part of the instrument seen at the right of fig. 1, falls upon the mirror, and is thence reflected to the graduated scale S, upon which it throws a line of light. The direction of the beam is indicated by the dotted lines. The image on the scale is made distinct by having the mirror ground slightly concave: this is shown in the section of the mirror and magnet, *m*, at the right of fig. 2. Now, the slightest motion of the magnet within the coil will cause twice the angular motion of the reflected ray; and as the scale can be placed at any distance from the mirror, the length of the luminous index can be proportionately increased, and thus an inappreciable deviation of the mirror can be indefinitely augmented. The sensitiveness of the galvanometer is still further increased by the use of the curved magnet M (fig. 1), which,

Fig. 2.



like the second needle in an astatic arrangement, is employed to neutralise the directive action of the earth upon the needle within the coil. The position of the poles, and the distance of this large magnet with respect to the needle, can be adjusted when necessary. This form of the reflecting galvanometer is of great value as an instrument for scientific research, and is exclusively employed for signalling through the Atlantic telegraph lines. [Telegraph, Submarine.]

Thomsonite. A hydrated silicate of alumina, lime, and soda, found in the basalt of Aberdeenshire, at the Kilpatrick hills, at the Giant's Causeway in Ireland, &c., generally in radiating masses of small prismatic crystals. Named after Prof. Thomson, of Glasgow, the discoverer.

Thoorgum. [Tycoon.]

Thor. In Teutonic Mythology, a son of Odin, the supreme god, and Freya his wife. He is a brother of Baldr, the glorious but short-lived hero, who in his life and death represents Achilleus, Rustem, and other solar heroes. Like Heracles, Thor journeys over sea and land, irresistible in his strength. He wears a strength belt, while his hands are sheathed in iron gloves, and his hammer splits the skulls of the giants and their kindred. Thor and the other children of Odin form the company of the Æsir, who are to reign until the twilight of the gods has come. This idea is seen in the Æschylean version of the legend of Prometheus, which asserts that the reign of Zeus and his partisans is one day to come to an end.

Thor, as the wielder of the hammer, or the smasher, is called, in northern mythology, Thor Miölnir, from the root *mar*, to crush, *grind*, or pound. [Language.] This name reappears in that of the Greek giants, Moliones, 'the sons of Molionê (*the mill*), and Aktor (*the corn-man*),' and again in that of the Aloadæ, Otos and Ephialtes, this name standing to Moliones in the relation of μόσχος to ὄσχος, *a branch* or *shoot*, and of ἄλευρον,

corn, to μάλευρον, a form mentioned by Helladius. To this same root belong apparently MARS, ARES, and the Sanscrit Maruts, or *the storms*. (Max Müller, *Lectures on Language*, 2nd series, vii.)

Thora. [SIGURDR.]

Thoracic Duct. The great trunk which conveys the contents of the lacteals and absorbents into the blood. In the human body it is about the diameter of a crow-quill, and lies upon the dorsal vertebræ between the aorta and azygos vein, extending from the posterior opening of the diaphragm, in a somewhat serpentine course, to the angle formed by the union of the left subclavian and jugular veins, into which it pours its contents. [CHYLE; LYMPH.]

Thoracics (Gr. θώραξ, *the chest*). The name given by Linnæus to those fishes which have the ventral fins placed beneath the pectorals.

Thorax (Gr.). The second segment of insects is so called by Latreille and Andouin; the term is restricted to the upper surface of the trunk by Linné and Fabricius. In Arachnidans the thorax and head are confluent, and form but one segment, which is termed the *cephalothorax*. As a cavity appropriated to the reception of the circulating and respiratory organs, the thorax is distinct only in Mammals.

THORAX. In Anthropotomy, the chest; the part of the body between the neck and the abdomen. It contains the heart and lungs, the œsophagus, the thymus gland, the thoracic duct, part of the aorta and vena cava, the vena azygos, the eighth pair of nerves, and a part of the great intercostal nerves.

THORAX. In Grecian Antiquities, a piece of defensive armour consisting of two parts, one defending the back, and the other the belly; called *lorica* by the Romans. The more ancient were made of padded linen; but they were also made of leather, brass, iron, and other metals.

Thoria or **Thorina** (from Thor, the Scandinavian deity). An earthy substance discovered, in 1828, by Berzelius in a rare Norwegian mineral called *thorite*, which is a hydrated silicate of thorina. Like the other earths, thorina is the oxide of a heavy grey metal, which has been termed *thorium*, and which is not acted upon by water, but when heated in the air it burns with great brilliancy into a white oxide. Thorina is white, infusible, and very heavy, its specific gravity being 9·4. It is insoluble in all acids except sulphuric, and in that with difficulty. Its equivalent is about 68. Thorina is distinguished from alumina and glucina by its insolubility in caustic potash, and from zirconia by being precipitated by ferrocyanide of potassium.

Thorite. Native hydrated silicate of thoria, found in the syenite of Lövön, near Brevig in Norway, in black, reddish-brown, or orange-yellow prismatic crystals. [ORANGITE.]

The metal thorium was first discovered in this mineral by Berzelius.

Thorn. A common name applied to various kinds of plants, which are furnished with thorns or spines. In this country it is especially applied to the *Cratægus Oxyacantha*, also known as the whitethorn, hawthorn, or quick, and so familiar as a hedge plant. The Blackthorn is *Prunus spinosa*; the Buckthorn, *Rhamnus*; the Camel's-thorn, *Alhagi Camelorum*; the Christ's Thorn, *Paliurus aculeatus*; and the Willow-thorn, *Hippophaë rhamnoides*.

Thorn Apple. [DATURA.]

Thornback. The name of a species of ray (*Raia clavata*, Linn.), distinguished by the short and strong recurved spines, rising from a broad osseous tubercular base, which are scattered over the back and tail. Two of these broad-based spines occupy the central ridge of the nose.

Thorough Bass. In Music, this expression is often used, though very objectionably, as synonymous with the science of harmony. In former times it was customary to consider the bass part as the principal element of the composition, to carry it completely *throughout* the piece, and to indicate the harmony by figures and signs placed above or below the bass notes; and the study of this *thorough bass* (*basso continuo*, or *general bass*, as it has been called) has hence come to be synonymous with the study of harmony generally.

Thoth, Thouth, Taout. An Egyptian divinity. His hieroglyphic represents the beginning of the astronomical year. He was regarded as the inventor of writing and Egyptian philosophy, and is represented as a human figure with the head of a lamb or ibis. (Plato, *Phædrus*; Plutarch, *De Is. et Osir.*; Wilkinson, *Ancient Egyptians*, vol. v.)

Thousand and One Nights. More commonly called among ourselves the *Arabian Nights' Entertainments*, from the title adopted in our first translation from Galland's version. A well-known collection of Oriental tales, which has acquired in the West a popularity never attained by any other Eastern composition. The history of the work has been the subject of much investigation, especially by De Sacy, Von Hammer, and Lane. According to Lane, the work, in its present form, is the composition of a single author living in Egypt, and was most probably 'not commenced earlier than the last quarter of the fifteenth century of our era, and completed before the termination of the first quarter of the next century, soon after the conquest of Egypt by the Osmanlee Turks in 1517.' But the origin of the tales is a much more difficult subject of enquiry. It seems to be now established (from the discoveries of De Sacy and Von Hammer) that there was an ancient Persian collection of stories, known by the name of the *Hezar Afzáneh* (the *Thousand Fanciful Tales*), of unknown antiquity, but certainly older than the ninth century of our era; that the framework of this collection was the same with that of the modern, viz. the story of the cruel king Shakryar and his ingenious queen Chehrazád; and that this was very

early translated into Arabic by the name of the *Thousand Nights*. But Mr. Lane differs from these learned Orientalists in still believing that the early work was only a model; that the greater proportion of the modern tales are really Arabian, especially all those founded on the supposed adventures of the Khalif Haroun and his queen Zobeyde, a few being only distinctly of Persian or Indian original; e.g. the *Magic Horse*, the *Damsel and the Seven Wezeers*. (De Sacy's Dissertation, prefixed to a late edition of Galland's version; Von Hammer's preface to that of Trébutien; Mr. Lane's Preface, and *Review* at the conclusion of his third volume.)

The *Arabian Nights* exhibit many features which are also seen in the mythology of Aryan nations, and for which no hypothesis of direct borrowing can account. Thus, the voyages of Sindbad contain some striking incidents in the legend of the Messenian hero Aristomenes, and Sindbad himself bears a strong likeness to Proteus and the Assyrian Oannes or Onnes. The tale of 'Ali Baba and the Forty Thieves' exhibits in some points a close correspondence with the story of Rhampsinitus (Herod. ii.), while, as a whole, it is identical with the tale entitled Simeli-Mountain, in Grimm's *Kinder- und Haus-Mährchen*. Tales in which magic carpets, invisible caps, tents capable of being rolled up into a hand's breadth and of containing a vast crowd, are common to the *Arabian Nights* fiction with the legends not only of Saracenic Spain, but of Germany and Iceland.

Thraêtana. In the Zend Mythology, a hero, who slays the biting serpent, Aji or Azi-dahaka, as Apollo slays PYTHON, and SIGURDR slays Fafnir. This Thraêtana of the Avesta is the Trita or Traitana of the Vedas, a name which reappears in Tritogeneia, an epithet of Athena. [MINERVA.] In the Trita, Yama, and Krisasva of the Veda we have the prototypes of Yima-Kshaêta, Thraêtana, and Keresaspa of the Avesta, the representatives of three of the earliest generations of mankind, just as the Germans spoke of the Ingævones, Herminones, and Iscævones as sprung from Mannus son of Tuisco (Tyr). These three names reappear in those of the three famous heroes of later Persian epic poetry, Jemshid, Feridún, and Garshasp. Of these, Feridún is the slayer of the tyrant Zohak, who is at once identified with Azi-dahaka, the biting serpent, the Ahi or throttling snake of Vedic mythology. As the slayer of his enemy Vritra, Indra is called Vritrahan, a name which (Vritra in the Zend being converted into Verethra) became Verethragna, and through the intermediate Pehlevi form *Phredun*, passed into the modern Persian Feridún. It has further been shown by Eugène Burnouf, that as in Sanscrit the father of Yama is Vivasvat, the father of Yima in the Avesta is Vivanghvat, and that the father of the Vedic Trita is Aptya, while the father of Thraêtana is Athwya. (Max Müller, *Lectures on Language*, second series, xi.; Bréal, *Hercule et Cacus* 130 &c.)

Thranite (Gr. θρανίτης, from θρᾶνος, *a bench*). The uppermost (or, according to some arrangements of the classical galley, the foremost) of the three classes of rowers in an Athenian trireme; the middle being called the *zeugitæ*, the lowest *thalamitæ*. [GALLEY; TRIREME.]

Thrashing (A.-Sax. therscan, Ger. dreschen). Separating grain or seeds from the straw or haulm by means of a flail or thrashing machine, or by treading with cattle. The latter was the mode employed in ancient times; and it is still practised in the south of Europe, and in Persia and India. The Romans employed oxen for this purpose; sometimes alone, and sometimes with the addition of a kind of roller studded with iron knobs, which they dragged over the corn, and which was spread on a circular floor, the driver standing in the centre, and guiding the oxen around him by means of reins. It was customary to allow the oxen occasionally to breathe and take a bite of the corn, agreeably to the Levitical precept. A kind of flail or rod was also sometimes used by the Romans, and is doubtless the origin of the present implement of that name. In colder and moister climates, such as that of Britain, where a floor sufficiently hard for thrashing out corn could not be maintained in the open air, thrashing appears to have been always performed under cover, and with the flail, till the latter end of the eighteenth century, when thrashing machines were introduced.

Thrashing Machine. A machine for separating corn or other seeds from the straw or haulm; and either impelled by horse or cattle, wind, water, or steam. The modern thrashing machine was invented in Scotland about the year 1758 by a farmer in the parish of Dumblaine, Perthshire, and afterwards brought to nearly its present state of perfection by Mr. Meikle, a millwright of Haddingtonshire, about the year 1798. Meikle's thrashing machine consists of a cylinder furnished with beaters fixed on its circumference, to which the corn is presented by rollers, the ears being thus beaten in pieces; and while the grain drops through a grating into a winnowing machine, the straw is carried forward, and delivered by itself ready to be made up into bundles. Some thrashing machines only beat out the corn, and separate it from the straw; while others beat it out, winnow it, and sift it, and deliver it in bags fit for market.

The employment of thrashing machines relieves the labourers from the severest drudgery incident to agriculture; they enable the work to be done at the time when there is a demand for corn; and, by doing it better, or separating the corn (particularly wheat) more completely from the straw, they add both to the wealth of the farmer and the produce of the country; enabling the former to employ, and the latter to feed, more labourers. The latter is, indeed, a most important consideration. It is calculated, by the best informed agriculturists, that 5 per cent., or one twentieth part, more produce is afforded

by a crop thrashed by machinery than by the old method; and, estimating the total produce of the corn crops of Great Britain and Ireland at 50,000,000 quarters, we should, on this hypothesis, have an additional annual supply of no less than 2,500,000 quarters, if thrashing machines were universally substituted for flails. So great an increase of produce in the hands of the farmers would obviously enable them to employ far more labourers than would be superseded by the use of the machine.

All thrashing machines are now driven by steam, and the work in England is generally accomplished by travelling engines and machines, the services of which are hired by the farmer.

Thraulite (Gr. θραυλός, *frangible*). A hydrated silicate of iron (a variety of Hisingerite) which occurs, with Magnetic Pyrites, at Bodenmais in Bavaria. It has a resinous fracture, and is very brittle.

Threatening Letters. The sending or delivering of letters threatening to publish, &c. libels, or to kill anyone, or demanding of any person with menaces any money or other valuable thing, or accusing or threatening to accuse any person of certain crimes, or the like, is punishable by English Law with imprisonment (with or without whipping) or penal servitude. (Stats. 6 & 7 Vict. c. 96; 24 & 25 Vict. cc. 96, 100.)

Three Bodies, Problem of the. A dynamical problem, of considerable celebrity, interest, and difficulty, the object of which may be said to be the determination of the circumstances attending the motion of three bodies, which mutually attract one another. In Physical Astronomy, the problem has, obviously, important applications; and accordingly it is to treatises on astronomy, and especially to the *Mécanique Céleste* of Laplace, that the reader must be referred for further information.

Three Chapters. In Ecclesiastical History. Under this name, the emperor Justinian condemned certain works of Theodore of Mopsuestia, Theodoret of Cyrus, and Ibas of Edessa, as being infected with the Nestorian heresy. (Milman, *Latin Christianity*, book iii. ch. iv.) [NESTORIANS.]

Three, Rule of. [RULE OF THREE.]

Threnody (Gr. θρηνῳδία, from θρῆνος, *a dirge*, and ᾠδή, *song*). A short species of occasional poem, on the death of some distinguished personage. [EPICEDIUM.]

Thridace (Gr. θρίδαξ, *lettuce*). *Lettuce opium*, called also *Lactucarium*. It is the inspissated juice of the common lettuce, which is slightly sedative.

Thrinax (Gr. *a three-pronged fork*). A small genus of Fan Palms, chiefly West Indian, of which some six or eight species are known, all comparatively low growing, seldom exceeding twenty feet in height, and frequently not more than ten; having their trunks clothed with the persistent bases of old leaves or marked with circular scars, and bearing a crown of much-cut fan-shaped leaves. In Jamaica they are commonly known by the name of Thatch-palms, their leaves being used for thatching, for which some of them are admirably adapted. One of them, *T. argentea*, is said to yield the young unexpanded palm-leaves imported from the West Indies under the name of Palmetto Thatch, and extensively employed for making palm-chip hats, baskets, and other fancy articles; but it is more than probable that the leaves are gathered from several species, while in the United States those of the allied genus *Sabal* are substituted. The tough leaf-stalks are also split into strips and woven into serviceable baskets, and the head of the undeveloped leaves or cabbage forms an excellent vegetable. *T. argentea* is likewise a native of Panama, where it is called *Palma de escoba*. or Broom-palm, its leaves being there made into brooms.

Throat (A.-Sax. throta). In Botany, the opening or orifice of a monopetalous corolla.

THROAT. On Shipboard, the wide end of a gaff next the mast. The opposite end is the *peak*.

Thrombolite (Gr. θρόμβος, *a lump*, and λίθος). Native hydrated phosphate of copper. It occurs amorphous, of an opaque green colour which becomes black on exposure to the air, at Rezbanya in Hungary, on limestone.

Thrombus (Gr. θρόμβος). A small tumour, which sometimes ensues in consequence of the escape of blood into the cellular membrane in the operation of bleeding.

Throne (Gr. θρόνος). In Architecture, a chair of state raised above the level of the floor on which it stands, usually richly ornamented and covered with a canopy.

Thrush. In Medicine. This disease, so named from its speckled appearance like that of the bird, consists in the formation of small white ulcers upon the tongue, palate, and gums, and is common in infants who are ill-fed or brought up by hand. It is apt to extend through the whole course of the mucous membrane lining the alimentary canal, exciting fetid eructations and flatulency, with a troublesome diarrhœa, and sometimes proves fatal. It is, however, nearly always confined to the mouth.

THRUSH (A.-Sax. drise, Ger. drossel). In Ornithology, one of the largest and most melodious of our native song birds; the type of the genus *Turdus* (Linn.). It is not migratory, but is supposed to quit the more northern parts of England in winter for the southern provinces. It makes its nest in March; lays four or five blue eggs, spotted with black at the larger end. It feeds on berries, insects, and shell-snails; and often selects a particular kind of stone, against which it breaks the shell of the snail, and near which a great quantity of fragments of the shells may be found.

Thrust (Lat. trudo, *I push*). In Architecture, the horizontal force of an arch, by which it acts against the piers from which it springs. Also a similar action of rafters or of a beam against the walls which bear them.

Thug (from the Hindee verb thugna, *to deceive*). A member of a singular association of robbers and murderers, which has existed for many ages in India. It appears that the existence of the system of *thuggee*, as it is called, was hardly known before the year 1810, and that no combined measures were taken to put a stop to it until about 1830. Since that time it has been fully detected and greatly checked, chiefly through the admission of approvers from all the gangs. Captain Meadows Taylor stated in 1839, that between 1831 and 1837, 3,266 Thugs were brought to justice, of whom 412 were hanged, 1,059 transported, and 483 turned approvers. Its origin is unknown; and both Mohammedans and Hindus belonged to the society indifferently, although its tutelary goddess, Bhowanee, is a Hindu deity. The Thugs were directed in all their proceedings by auguries supposed to be vouchsafed by their goddess; and particular classes were altogether exempt from their attacks: among these were dancing girls, minstrels, sikhs, some religious mendicants, tailors, oilmen, blacksmiths, carpenters. It is stated that they seldom destroyed women unless for their own safety; and they very seldom ventured to attack Englishmen. They usually moved in large gangs, and attached themselves to travelling parties, with whom they would journey for days, until they found an opportunity for mastering them. When all was ready, one division of the murderers strangled the victims, while another body prepared their graves; and by means of this division of labour the fearful work was accomplished with wonderful celerity. It appears that numbers of Thugs resided together in villages, where they were protected by the landowners, and sometimes by rajahs, to whom they paid tribute. The destruction of life occasioned by them may be conjectured from the fact that one Thug, admitted an approver at Saugor, confessed to Col. Taylor, who does not seem to suspect him of exaggeration, that he had been concerned in the murder of 719 persons. The existence of so strange and monstrous a system can only be explained by the condition of India; the extreme timidity and apathy of its inhabitants, and their division into castes; the number of small native governments; the habit of dwelling in villages, divided by extensive uninhabited tracts; the frequency of travellers in that commercial country, which had no navigable rivers or secure conveyances; and the murderous spirit of Hindu fanaticism. In 1848, Sir W. Sleeman (who had done invaluable service towards their suppression) was of opinion that the 'old Thug associations were effectually put down.' But under the cognate form of 'dacoity,' robbery by armed bands long continued a common occurrence, and a special police was maintained for its suppression, until 1863, and is still continued in some native protected states, where the spirit of Thuggee is thought to survive. (See Sir W. Sleeman's *Ramasceana, Vocabulary of the Thugs*, and an article on it in the *Ed. Rev.* vol. lxiv.; and Col. Meadows Taylor's *Adventures of a Thug*, 2 vols. Lond. 1839.)

Thuja (Gr. θύος). One of the genera of the cupressineous division of *Coniferæ*, consisting of evergreen trees, natives of North America. One species is very common in English gardens under the name of Arbor Vitæ, the origin of which designation is uncertain. The branches are very numerous, the smaller ones arranged in two rows, and covered with small closely-pressed lozenge-shaped leaves arranged in four ranks. *T. occidentalis*, the American Arbor Vitæ, is a hardy evergreen shrub, everywhere pervaded with a powerful aromatic odour. The leaves have been used as a remedy for rheumatism, on account of their sudorific properties, and in America the wood is used for posts and other similar purposes. *T. orientalis*, the Chinese Arbor Vitæ, is sometimes separated under the name of *Biota*, on account of its roundish cones, more numerous scales, and wingless seeds. It is a native of Japan, China, &c., and is of a closer habit, with its branches directed more vertically upwards, and its leaves smaller and more densely packed than in the American species. This plant has a pungent aromatic odour; the young branches are said to be used for a yellow dye, and the wood is made use of where something is required to withstand humidity.

Thule. The name given by the ancients to some undefined part of the world, apparently to the north of Britain, as in the following lines of Seneca:—

> ——Venient annis
> Secula seris, quibus Oceanus
> Vincula rerum laxet, et ingens
> Pateat tellus, Typhisque novos
> Deteget Orbes, nec sit terris
> Ultima Thule.

On the connection of the inconsistent tales respecting Thule with the alleged commercial navigation of the Phœnicians, see Sir G. C. Lewis, *Astronomy of the Ancients*, p. 467 &c.

Thulite. A rose-coloured variety of Epidote, containing cerium, found in Norway at Sonland in Tellemarken, and lately discovered at Traversella in Piedmont. The name is derived from THULE.

Thumerstone. A Mineralogical name for Axinite, first found at Thum in Saxony.

Thummim. [THMEI; URIM.]

Thunder (Ger. donner, Lat. tonitru, from a root tan, *to stretch*, which is found in Gr. τείνω, Lat. tendo, Eng. *tone*, &c.). The noise produced by the passage of lightning through the air from one cloud to another, or from a cloud to the ground.

The character of the sound of thunder varies with the force and the distance of the explosion, the situation of the observer, and the nature of the surrounding country; and it is probably influenced also by the relative situations of the clouds.

When lightning strikes an object near us on the earth, it produces a noise resembling

that of a violent crash, which is not repeated or prolonged by reflection. When the explosion is more distant, a rumbling, irregular, and recurring noise is heard, which gradually dies away in the distance, like the prolonged echo of the sound of ordnance discharged in a mountainous district.

Thunder frequently commences with an astounding rattle, which is probably occasioned by a series of discharges of electric matter in rapid succession from a highly charged thunder cloud.

We have a familiar example of this species of noise in the cracking sound which accompanies the sparks discharged from the conductor of a well-supplied electrical machine towards any adjacent conducting body; the loudness of the snaps, as well as their frequency, increasing with the electric intensity. And when we consider how trifling a portion of electric matter can be put in action by the most powerful means of artificial excitement compared with the quantity stored up in a full-charged thunder cloud, the discrepancy between the appalling crash of the one and the insignificant snap of the other will not appear surprising, although both originate in the same cause.

This cause is the production of an air-wave by the sudden expansion of that portion of air which lies in the direct path of the electric discharge, and which becomes so intensely heated as to produce also the luminosity of lightning. This air-wave is propagated like other sound waves, and impinging upon the auditory nerves gives rise to the sensation of sound. The sound produced by the discharge of cannon is due to precisely the same cause, the only difference being that the air-wave is here produced by the sudden generation as well as expansion of gaseous matter. The continued roll of thunder is the effect of the comparatively slow propagation of sound through the air. For the sake of illustration, suppose a flash of lightning of 11,250 feet in length, or that the spark is instantaneously seen from one end to the other of this line. At the same instant the flash is visible the vibration is communicated to the atmosphere through the whole extent of the line. Now suppose an observer placed in the direction of the line of the flash, and at the distance of 1,125 feet from one end, then, since sound travels at the rate of about 1,125 feet in a second [SOUND], one second will elapse after the flash has been seen before any sound is heard. When the sound begins, the vibration communicated to the nearest stratum of air has reached his ear; and since we have supposed the line of disturbance to be 11,250 feet in length, the vibrations of the more distant strata will continue to reach his ear in succession during the space of ten seconds. Hence the length of the flash determines the duration of the sound; and it follows that the same flash will give rise to a sound of greater or less duration, according to the position of the observer with respect to its direction. Thus, in the above instance, suppose a second observer to be placed under the line, and towards its middle, he would only hear the sound during half the time it was heard by the first observer; and if we suppose the line to be circular, and the observer to be placed near its centre, the sound would arrive from every point at the same instant in a violent crash.

Thunder Dirt. The New Zealand name for the gelatinous volva of *Ileodictyon*, which is, or was formerly, eaten by the natives.

Thuringite. A hydrated silicate of alumina, and the protoxide and peroxide of iron, which occurs in the form of an aggregation of minute olive-green scales, at Schmiedfeld, near Saalfeld, in Thuringia; whence the name.

Thurls. Short communications between the adits in mines.

Thursday (A.-Sax. thunres-dæg). The fifth day of the week. The word contains the name of THOR, as Friday bears that of Freya.

Thus (Lat.; Gr. θύος). Frankincense, a resinous exudation from *Abies excelsa*.

Thwarts (Dutch dwars, Dan. tvers, Swed. tvars). The cross beams of an open boat, forming seats for the rowers and bracing the sides together.

Thylacinus (a word coined from the Gr. θύλαξ, *a pouch*, and κύων, *a dog*). A genus of carnivorous marsupials. The *Thylacinus* or *Peracyon cynocephalus* (zebra wolf of the Tasmanian colonists) is of the size and form of a wolf, but lower in the legs. It is transversely striped with black on a russet ground. In this genus the *ossa marsupialia* are wanting, being merely represented by fibro-cartilages in the external oblique muscles of the abdomen.

Thylacoleo (Gr. θύλαξ, and λέων, *a lion*). A genus of carnivorous marsupials, which existed during the pliocene period in Australia; its marsupial nature was demonstrated by the position of the lacrymal foramen in front of the orbit, by the palatal vacuity, the loose tympanic bone, the developement of the tympanic bulla in the alisphenoid, and the very small relative size of the brain. These characters distinguished it from the placental diphyodont carnivora, evidence of which in Australia has not been demonstrated during either geological or recent periods. The species *Thylacoleo carnifex* equalled the lion in size.

Thymeleaceæ (Thymelea, one of the genera). A natural order of shrubby perigynous Exogens, having a calyx only, and no corolla, although the flowers of many are coloured very gaily. The order is chiefly characterised by a tubular perianth, with four or five lobes, and bearing as many or twice as many stamens in its tube, and often small scales at the mouth; and by a simple ovary within the perianth-tube, with a short simple style, and a single pendulous ovule. *Daphnes*, valued for their fragrance, *Mezereum*, the various species of the Australian genus *Pimelea*, and the *Gnidias* and *Struthiolas* of the Cape of Good Hope, are favourite subjects of cultivation. One feature of the order is the causticity of the bark,

which acts upon the skin as a vesicatory, and causes excessive pain in the mouth if chewed. The berries of *Daphne Laureola* (the Spurge Laurel) are poisonous to all animals except birds.

Thymoyl. The product of oxidation of thymol: it contains $C_{24}H_{16}O_4$.

Thymoylol ($C_{24}H_{18}O_4$). An organic compound produced by the prolonged action of sulphurous acid on thymoyl.

Thymus (Lat.; Gr. θύμος, *thyme*). A genus of *Labiatæ*, widely dispersed over Europe, Northern Africa, and Central Asia, but most abundant in the Mediterranean region.

The Wild Thyme, *T. Serpyllum*, is common throughout temperate Europe and Asia, and Northern Africa. The common or Garden Thyme, *T. vulgaris*, which grows more erect than the Wild Thyme, is a native of Spain and Italy. Its uses are well known. The leaves, both in a green or dried state, are employed for seasoning soups, stews, sauces, and stuffings, to which they give an agreeable and highly aromatic flavour. In the South of France an essential oil distilled from it is imported into this country and sold as Marjoram oil, for which it is substituted. It yields a species of camphor by distillation with water, and in Spain they infuse it in the pickle with which they preserve their olives. The Romans were well acquainted with Thyme, which was one of the plants recommended to be grown for the sake of bees. The Lemon-scented Thyme is a hardy dwarf trailing evergreen, possessing the most agreeable perfume of any of its genus. It has long been cultivated in this country, and is used for the same purposes as the other species. It attains the greatest perfection when grown in dry light sandy soil.

Thymus Gland (Gr. θύμος). A gland situated under the upper part of the sternum, in the anterior mediastinum. It belongs to the class of ductless glands. It is of great comparative size in the fœtus.

Thynnus (Lat.; Gr. θύννος, *a tunny*). A genus of Scomberoid fishes, of which the highly valuable fish the tunny (*Thynnus vulgaris*, Cuv.) is the type. The form of the body in this genus of fishes is like that of the mackerel, but is less compressed; the first dorsal fin extends nearly to the second; the second dorsal and the anal fins are divided into numerous finlets: the sides of the tail are decidedly carinated; there is a single row of small pointed teeth in each jaw. The tunny is remarkable among fishes for its high temperature, its perfect respiratory organs, the quantity of nerves supplying the gills, and the general abundance of rich red blood throughout the body. It is the object of the most important fisheries in the Mediterranean Sea. The *bonito* (*Thynnus pelamys*) is a species of this genus of fishes.

Thyris (Gr. θυρίς, *a window*). A genus of butterflies.

Thyroid (Gr. θυροειδής, *like a door*). The thyroid or scutiform cartilage is placed perpendicular to the cricoid cartilage of the larynx, of which it forms the upper and anterior part. In men it is harder and more prominent than in women; it is sometimes called *Adam's apple*. The thyroid gland is situated upon the thyroid and cricoid cartilages of the trachea: it is of the class of ductless glands. When enlarged, it forms the bronchocele.

Thyrsula (Lat. thyrsus; Gr. θύρσος, *a sprout* or *stem*). The little cyme which is borne by the greater part of labiates in the axils of their leaves. It is sometimes called a *verticillaster*.

Thyrsus (Gr. θύρσος). A staff entwined with ivy, which formed part of the accoutrement of a Bacchanal, or performer in the orgies of Bacchus.

Thyrsus. In Botany, a form of inflorescence, consisting of a compact panicle, the lower branches of which are shorter than those of the middle; in other words, it is composed of a primary axis developing secondary axes from its sides, which in their turn develope tertiary axes, the upper and lower branches being shorter than those of the middle, as in the common Lilac.

Thysanurans (Gr. θυσάνουρος, *with a rough* or *fringed tail*). The name of an order of Ametabolian insects, comprehending those in which the abdomen is terminated by filaments, or by a forked tail adapted for leaping.

Tia. A Chinese name for *Sageretia theezans*.

Tiara (Lat.; Gr. τιάρας). An ornament with which the ancient Persians adorned their heads, in the form of a tower, ornamented with peacock's feathers. Xenophon says that it was sometimes encompassed with the diadem, and had frequently the figure of a half moon embroidered upon it.

This was the name also originally given to the mitre of the popes. It was nothing more than a round high cap, at first single instead of double, like that of other bishops. Nicholas I. added the first gold circle, as the sign of the civil power. The second was added by Boniface about 1300; the third by Urban V. about 1365. (Bowden, *Life of Gregory VII.* i. 60.)

Tiber Stone (Lat. Lapis Tibertinus). A name given to Travertine in consequence of the vast deposits of that substance formed by the water of the river Tiber.

Tibia (Lat.). In Anatomy, the largest of the two bones which form the second segment of the leg, or sacral extremity. In Entomology, it is the fourth joint of the leg, is very long, and usually triquetrous. It is said to have been so named from its resemblance, in the human skeleton, to the ancient pipe or flute.

Tic Douloureux (Fr.). A very painful affection of a nerve, coming on in sudden and excruciating attacks: it is perhaps most common in that branch of the fifth pair which comes out of the infra-orbitary foramen. The cause of tic douloureux is generally obscure;

occasionally it has been traced to disease of bone where spiculæ have been found pressing on the nerves. The treatment is uncertain, except where it assumes an intermittent form, and then large doses of tonics, especially quinine, arsenic, and carbonate of iron, have proved useful.

Tichorhine (Gr. τεῖχος, *a wall*, and ῥίς, ῥινός, *a nose*). The name of a fossil species of rhinoceros (*Rhinoceros tichorhinus*), so called from the middle vertical bony septum or wall which supports the nose.

Ticket of Leave. During the continuance of the system of transportation as an ordinary punishment, the practice was to release convicts, of good behaviour, before the regular expiration of their sentence, with a ticket of leave, i.e. a license to be at large, forfeitable on misconduct. When transportation was superseded by penal servitude, a similar system was introduced into convict prisons in England. [TRANSPORTATION.]

Tide Gauge. A mechanical contrivance for registering the state of the tide continuously at every instant of time. In the *Phil. Trans.* for 1838, there is a description of a very complete self-registering machine for this purpose, erected at Bristol by Mr. Bunt. The principal parts are an eight-day clock, which turns a vertical cylinder revolving once in twenty-four hours; a wheel, to which an alternate motion is communicated by a float rising and falling with the tide, and connected with the wheel by a wire passing over a pulley, and kept constantly strained by a counterpoise: and a small drum on the same axis with the wheel, which communicates one-eighteenth of the motion of the float to a bar carrying a pencil, which describes a curve on the cylinder, and marks the fluctuations and the time and height of high water. Various tide gauges, on similar principles, have been constructed by others, particularly by Captain Lloyd, Mr. Mitchell, Mr. Palmer, Mr. Bunt, Mr. Hewitson, and Mr. Newman. The chief improvements recently introduced into tide gauges are exhibited in that constructed by Hewitson. Great pains have been taken in every part of its construction to diminish friction as much as possible. The teeth of the wheels are carefully made, so that if the rise or fall of the tide should amount to the fraction of an inch only, a simultaneous movement of the machine follows to that amount. It is furnished with a brass cylinder turning on axes of bell-metal revolving in Y's. The traversing bar carrying the registering pencil moves on steel friction rollers, concealed in the capitals of the brass supporting pillars. The machine is connected with an astronomical clock, which needs winding only once in sixteen days, or in rather more than half a lunation, and thus produces, without any attention in this interval, a complete chart of tidal curves. (See the *Nautical Magazine* for October, 1832; *Phil. Trans.* for 1831 and 1838; and *Jury Report*, Class 10, *of the Great Exhibition of* 1851.)

Tide Mills. Mills which have the ebb and flow of the tide for their first movers. As the tide rises, the water is admitted into a reservoir through a sluice, over which the mill is built, turning the water-wheel in its passage through the sluice. At high tide the sluice gates are shut till the water has fallen sufficiently outside, when they are opened, so as to allow the water to flow out again from the reservoir, and turn the wheel as it escapes through the sluice.

In some tide mills the water-wheel turns one way as the tide rises, and the contrary as it falls; but in others an arrangement is adopted by which the wheel is made to turn always in the same direction. In some, the water-wheel rises and falls with the tide; and in others, the axis is fixed, so that it can neither rise nor fall. In the latter case, the power is applied at an obvious disadvantage. Instead of a water-wheel, a turbine may be employed to derive motion from the tide; or a species of blade may be used like the sails of a windmill, but with such a preponderance of surface on one side of the blade as to twist it into a right-hand screw when the water is rising and a left-hand screw when the water is falling, or vice versâ. By this arrangement the revolving axis will always be turned in the same direction, whether the tide is rising or falling.

Tides (A.-Sax. tid, Ger. zeit, Dutch tyd, *time*). The alternate rise and fall of the waters of the ocean. The moon is the principal agent in the production of the tides; but they are modified, both with respect to their height and the times at which they happen, by the action of the sun. The effect of the planets is inappreciable.

The attractive force of a body on a distant particle of matter varying inversely as the square of the distance, the particles of the earth on the side next the moon will be attracted with a greater, and those on the opposite side with a smaller force, than those which are situated intermediately. The gravitation towards the earth's centre of the particles nearest the moon will therefore be diminished, and consequently, if at liberty to move among themselves, they will rise above the general level. In like manner, the moon's attraction on the most distant particles being less than on the central ones, their relative gravitation towards the centre will also be diminished, and the waters will consequently be heaped up on the side of the earth which is turned away from the moon. Hence, if the earth were at rest, the ocean would take the form of an oblong spheroid, with its longer axis passing through the attracting body; and it may be shown from theory that the spheroid would be in equilibrium under the influence of the moon's attraction, if the longer semi-axis exceeded the shorter by about fifty-eight inches. But in consequence of the rapid rotation of the earth about its axis, the spheroid of equilibrium is never fully formed; for before the waters can take their level, the vertex of the spheroid has shifted its position on the earth's surface, in consequence of which an immensely broad and very flat

wave is formed, which follows the motions of the moon at some interval of time. In the open sea the time of high water is, in general, from two to three hours after the moon's transit over the meridian either above or below the horizon. The tidal wave, it is to be observed, is entirely different from a current: the particles of water merely rise and fall; but except when the wave passes over shallows, or approaches the shore, there is little or no progressive motion.

The waters of the ocean are affected in a similar manner by the action of the sun, under the influence of which they have a tendency to assume at every instant the form of an elongated spheroid; but although the attractive force of the sun is immensely greater than that of the moon, yet, by reason of his greater distance, the *difference* of the effect on particles situated on opposite sides of the earth (on which difference the phenomena depend) is very much less. The solar tides are therefore comparatively small with respect to the lunar tides, and, in fact, are never perceived as distinct phenomena, but become sensible only from the modifications which they produce in the heights and times of those which primarily depend on the moon. At the syzigies, when the sun and moon come to the meridian together, the tides are, *cœteris paribus*, the highest; at the quadratures, or when the sun and moon are 90° distant, the tides are least. The former are called *spring tides*, the latter *neap tides*. Although we are not in possession of data to enable us to compute the exact height either of the spring or neap tides, yet their relative heights in the open ocean probably correspond very nearly to the ellipticities of the spheroids of equilibrium that would be formed under the action of the two bodies exerted separately. Now, the ellipticity of the aqueous spheroid formed by the moon's action is about five feet, and the ellipticity of that formed by the sun's action about two feet; therefore, the spring and neap tides being the sum and difference of the separate effects, the average spring tide will be to the average neap in the ratio of about 7 to 3; i.e. of $5+2:5-2$. [GRAVITATION.]

By reason of the eccentricities of their orbits, the distances of the sun and moon from the earth are continually changing; and the theory of attraction proves that the efficacy of either body in disturbing the waters of the ocean is inversely proportional to the cube of its distance. Hence it is found that if the mean efficacy of the sun be represented by 20, the influence of the sun's action will vary between the extremes of 19 and 21, and that of the moon's between 43 and 59. The highest spring tide will therefore be to the lowest neap as $59+21$ to $43-19$; i.e. as 80 to 24, or as 10 to 3.

Another effect of the solar action is observed in the times at which high water takes place from day to day. In the spring and neap tides the time of high water is not altered by the sun's action, the solar and lunar tides being synchronous in the former case, and the time of actual low water being that of solar high water in the latter; but in the intermediate tides the time of actual high water is accelerated or retarded. In the first and third quarters of the moon, the solar wave is to the westward of the lunar one; and consequently the observed tide, which is the result of the combination of the two waves, will be to the westward of the place which it would occupy if the moon acted alone, and the time of high water will therefore be accelerated. In the second and fourth quarters, the general effect of the sun is to produce, for a like reason, a retardation in the time of high water. This result of the combined action of the two attracting bodies is what is usually termed the *priming and lagging* of the tides, and is most remarkable about the times of new and full moon.

It is to be observed, however, that the effect now described is modified to some extent by the inertia of the water. The greatest and least tides do not happen exactly at the times of new and full moon; but at least two, and commonly three tides after, even at places directly exposed to the general tide of the ocean. In consequence of the greater amount of impressed force, the acceleration of the lunar tide is greater than that of the solar; whence it may happen that when the lunar tide occurs two or three hours after the transit of the moon, the solar tide may be three or four hours after that of the sun, so as to be about an hour later at the times of conjunction and opposition. The highest spring tides will thus occur when the moon passes the meridian about an hour after the sun; while at the precise time of new and full moon the lunar tide will be retarded about a quarter of an hour by the solar tide. But the time of high water does not follow the moon's transit at the same interval at every period of the lunation. When the sun and moon are in conjunction, the interval is called the *mean interval*; at other periods of the lunation the lunitidal interval is sometimes greater and sometimes less than the mean, and the difference is called the *half-monthly* or *semi-menstrual inequality*.

The apparent time of high water at any port, in the afternoon of the day of new or full moon, is what is usually called the *establishment of the port*. Dr. Whewell calls this the *vulgar* establishment, and the mean of all the intervals of tide and transit for a half lunation he terms the *corrected* establishment. This corrected establishment is consequently the lunitidal interval corresponding to the day on which the moon passes the meridian exactly at noon or midnight.

The two tides immediately following one another, or the tides of the day and night, vary, both in height and time of high water, at any particular place with the distance of the sun and moon from the equator. As the vertex of the tide wave always tends to place itself vertically under the luminary which produces it, it is evident that, of two consecutive tides, that which happens when the moon is nearest the zenith or nadir will be greater than the other;

and consequently when the moon's declination is of the same denomination as the latitude of the place, the tide which corresponds to the upper transit will be greater than the opposite one, and vice versâ, the differences being greatest when the sun and moon are in opposition and in opposite tropics. This is called the *diurnal inequality*, because its cycle is one day; but it varies greatly at different places, and its laws, which appear to be governed by local circumstances, are very imperfectly known.

We have now described the principal phenomena that would take place if the earth were a sphere and covered entirely with a fluid of uniform depth. But the actual phenomena of the tides are infinitely more complicated. From the interruption of the land, and the irregular form and depth of the ocean, combined with many other disturbing circumstances—among which are the inertia of the waters, the friction on the bottom and sides, the narrowness and length of the channels, the action of the wind, currents, difference of atmospheric pressure, &c. &c.—great variation takes place in the mean times and height of high water at places differently situated; and the inequalities above noticed, as depending on the parallax of the moon, her position with respect to the sun, and the declination of the two bodies, are, in many cases, altogether obliterated by the effects of the disturbing influences, or can only be detected by the calculation and comparison of long series of observations.

By reason of these disturbing causes, it becomes a matter of great difficulty to trace the propagation of the tide wave, and the connection of the tides in different parts of the world. In the *Philosophical Transactions* for 1832, Sir John Lubbock published a map of the world, in which he inserted the times of high water at new and full moon at a great number of places on the globe, collected from various sources, as works on navigation, voyages, sailing directions, &c.; and in order that the march of the tide wave might be traced more readily, the times were expressed in Greenwich time as well as the time of the place. In the same *Transactions* for 1833, Dr. Whewell prosecuted this subject at greater length; and availing himself of à priori considerations, as well as of a mass of information collected in the Hydrographer's Office at the Admiralty, inserted in the map a series of *cotidal lines*, or lines along which high water takes place at the same instant of time. But these cotidal lines, as Sir J. Lubbock remarks, are entirely hypothetical; for we have few opportunities of determining the time of high water at a distance from the coast, though this is sometimes possible by means of a solitary island, as St. Helena. (Lubbock's *Elementary Treatise on the Tides*, 1839.)

According to Dr. Whewell's deductions, the general progress of the great tide wave may be thus described: It is only in the Southern Ocean, between the latitudes of 30 and 70 degrees, that a zone of water exists of sufficient extent to allow of the tide wave being fully formed. Suppose, then, a line of contemporary tides, or *cotidal line*, to be formed in the Indian Ocean, as the theory supposes, i.e. in the direction of the meridian, and at a certain distance to the eastward of the meridian in which the moon is. As this tide wave passes the Cape of Good Hope, it sends off a derivative undulation, which advances northward up the Atlantic Ocean, preserving always a certain proportion of its original magnitude and velocity. In travelling along this ocean the wave assumes a curved form, the convex part keeping near the middle of the ocean, and ahead of the branches, which, owing to the shallower water, lag behind on the American and African coasts; so that the cotidal lines have always a tendency to make very oblique angles with the shore, and, in fact, run nearly parallel to it for great distances. The main tide, Dr. Whewell conceives, after reaching the Orkneys, will move forward in the sea bounded by the shores of Norway and Siberia on the one side, and those of Greenland and America on the other, will pass the pole of the earth, and finally end its course on the shores in the neighbourhood of Behring's Straits. It may even propagate its influence through the straits, and modify the tides of the North Pacific. But a branch tide is sent off from this main tide into the German Ocean; and this, entering between the Orkneys and the coast of Norway, brings the tide to the east coast of England, and to the coasts of Holland, Denmark, and Germany. Continuing its course, part of it at least passes through the strait of Dover, and meets in the British Channel the tide from the Atlantic, which arrives on the coast of Europe twelve hours later; but in passing along the English coast another part of it is reflected from the projecting land of Norfolk upon the north coast of Germany, and again meets the tide wave on the shores of Denmark. Owing to this interference of different tide waves, the tides are almost entirely obliterated on the coast of Jutland, where their place is supplied by continual high water.

In the Pacific Ocean the tides are very small: but there are not sufficient observations to determine the forms and progress of the cotidal lines. Off Cape Horn, and round the whole shore of Tierra del Fuego, from the western extremity of the strait of Magalhaens to Staten Island, it is very remarkable that the tidal wave, instead of following the moon in its diurnal course, travels to the *eastward*. This, however, is a partial phenomenon; and a little farther to the north of the last-named places the tides set to the north and west. In the Mediterranean and Baltic seas the tides are inconsiderable, but exhibit irregularities for which it is difficult to account. The Indian Ocean appears to have high water on all sides at once, though not in the central parts at the same time.

Since the tides on our coasts are derived from the oscillations produced under the direct agency of the sun and moon in the Southern

Ocean, and require a certain interval of time for their transfer, it follows that, in general, the tide is not due to the moon's transit immediately preceding; but is regulated by the position which the sun and moon had when they determined the primary tide. The time which intervenes between the original formation of the tide and its appearance at any place is called the *age* of the tide, and sometimes, after Bernoulli, the *retard*. On the shores of Spain and North America the tide is a day and a half old; in the port of London, it appears to be two days and a half old when it arrives.

Velocity of the Tide Wave.—In the open ocean the crest of the tide travels with enormous velocity. If the whole surface were uniformly covered with water, the summit of the tide wave, being mainly governed by the moon, would everywhere follow the moon's transit at the same interval of time, and consequently travel round the earth in a little more than twenty-four hours. But the circumference of the earth at the equator being about 25,000 miles, the velocity of propagation would therefore be about 1,000 miles per hour. The actual velocity is perhaps nowhere equal to this, and is very different at different places. In latitude 60° south, where there is no interruption from land (excepting the narrow promontory of Patagonia), the tide wave will complete a revolution in a lunar day, and consequently travel at the rate of 670 miles an hour. On examining Dr. Whewell's map of cotidal lines, it will be seen that the great tide wave from the Southern Ocean travels from the Cape of Good Hope to the Azores in about twelve hours, and from the Azores to the southernmost point of Ireland in three hours more. In the Atlantic the hourly velocity in some cases appears to be 10° of latitude, or near 700 miles, which is almost equal to the velocity of sound through the air. From the south point of Ireland to the north point of Scotland the time is eight hours, and the velocity about 160 miles an hour along the shore. On the eastern coast of Britain, and in shallower water, the velocity is less. From Buchanness to Sunderland it is about 60 miles an hour; from Scarborough to Cromer, 35 miles; from the North Foreland to London, 30 miles; from London to Richmond, 13 miles an hour in that part of the river. (Whewell, *Phil. Trans.* 1833 and 1836.) It is scarcely necessary to remind the reader that the above velocities refer to the transmission of the undulation, and are entirely different from the velocity of the current to which the tide wave gives rise in shallow water.

Range of the Tide.—The difference of level between high and low water is affected by various causes, but chiefly by the configuration of the land, and is very different at different places. In deep inbends of the shore, open in the direction of the tide wave, and gradually contracting like a funnel, the convergence of the water causes a very great increase of the range. Hence the very high tides in the Bristol Channel, the bay of St. Malo, and especially the bay of Fundy, where the tide is said to rise sometimes to the height of 100 feet. Promontories, under certain circumstances, exert an opposite influence, and diminish the magnitude of the tide. The observed ranges are also very anomalous. At certain places on the south-east coast of Ireland the range is not more than 3 feet, while at a little distance on each side it becomes 12 or 13 feet; and it is remarkable that these low tides occur directly opposite to the Bristol Channel, where (at Chepstow) the difference between high and low water amounts to 60 feet. In the middle of the Pacific it amounts only to 2 or 3 feet. At the London Docks the average range is about 22 feet; at Liverpool 15·5 feet; at Portsmouth 12·5 feet; at Plymouth also 12·5 feet; at Bristol 33 feet.

Theory of the Tides.—The theory of the tides, considered as a consequence of solar and lunar attraction, was first sketched by Newton in the *Principia*. In the thirty-sixth and thirty-seventh propositions of the third book, he determines the forces of the sun and moon to elevate the waters of the ocean, on the supposition that the sea is a fluid of the same density as the earth, covering the whole terrestrial surface, and which takes at every instant the figure of equilibrium. He assumes, without demonstration, that this figure is an elongated spheroid. One spheroid he supposes to be formed under the action of the sun, another under the action of the moon; and by reason of the smallness of their eccentricities they may be conceived as superposed the one on the other. From these suppositions he deduced the general phenomena of the ebb and flow of the sea; and by comparing his theory with observations of the heights of the spring tides made at the mouth of the Avon, near Bristol, he determined the ratio of the attraction of the moon to that of the sun to be nearly 4·48 to 1; whence he deduced the mass of the earth to be to that of the moon as 39·788 to 1, the density of the sun to that of the earth as 1 to 4, and the density of the moon to that of the earth as 11 to 9. Newton's theory was defective in many points of view; but fifty years elapsed before it received any improvement. In 1738, the subject of the tides was proposed as a prize question by the French Academy of Sciences, which gave occasion to the celebrated treatises of Daniel Bernoulli, Maclaurin, and Euler. Maclaurin's Essay is remarkable, as containing a demonstration of the theorem assumed by Newton, that the elliptic spheroid affords an equilibrium under the action of the disturbing forces: those of Bernoulli and Euler, though they furnish no new principle of equal or similar importance in point of theory, enter more into details, and contain many useful illustrations. That of Bernoulli, indeed, contains a table which has served as the model for all those (not purely empirical) which have since been formed. The next important step in the theory of the tides was taken by Laplace, who first treated the subject as a general question

of hydrodynamics, and attempted to deduce the principal phenomena from the equations of the motions of fluids. But in order to simplify the equations, which are of a very complicated nature, he was forced to have recourse to the hypothesis of a fluid covering entirely a spheroid of a regular surface, and consequently the results were far from representing the actual observations of the tides at any port. The late Dr. Thomas Young (*Ency. Brit.* art. 'Tides') extended Laplace's method to the more general case of an ocean covering a part only of the earth's surface, and more or less irregular in its form; and attempted also to include in his calculation the effects of hydraulic friction on the times and magnitudes of the tides. It is, however, quite impossible to embrace in any calculation the whole of the accessory circumstances which influence the times and magnitudes of the tides, the greater part of which are, in fact, entirely unknown; and therefore Laplace maintains that we can do no more than analyse the general phenomena which should result from the joint action of the sun and moon, and deduce from observations the data indispensable for completing the theory of the tides for each particular port.

A great number of observations of the tides at the port of Brest, during the last century, were discussed by Laplace in the *Mécanique Céleste*; but in order to determine the motion of the tide wave, and separate the general laws of the phenomena from local irregularities, it is necessary to have regular series of observations made at different parts of the ocean. In 1829, Sir John Lubbock undertook the discussion of the tide observations which are made at the London Docks, with the view of obtaining correct tables for predicting the time and height of the tides for the *British Almanac.* The results, which were published in the *Philosophical Transactions* for 1831, are deduced from a series of upwards of 13,000 observations, during a period of nineteen years, and are of great importance, both as affording materials for the construction of tide tables, and as pointing out the defects of the equilibrium theory, with which they were accurately compared. In some of the subsequent volumes of the *Transactions* the author has continued his investigations, and has also published, separately, an account of Bernoulli's *Traité sur le Flux et Reflux*, and an elementary treatise, which appeared in 1839. In the *Phil. Trans.* for 1833, Dr. Whewell gave an *Essay towards a first Approximation to a Map of Cotidal Lines*, which has been followed by a series of interesting papers in the subsequent volumes to the year 1850. Dr. Whewell's researches were chiefly directed to the determination of the following points: First, the motion of the tide wave at different parts of the ocean; secondly, the comparison of the observed laws at different places with theory; and, lastly, the laws of the diurnal inequality. In 1834, the British Association caused an extensive series of observations to be made on the coasts of Britain and Ireland at 537 stations of the coast-guard. These were repeated at the same places in June 1835; and, at the request of our government, simultaneous observations were made by the other maritime powers of Europe and the United States. The number of stations in America was twenty-eight, extending from the mouth of the Mississippi to Nova Scotia; and the number on the continent of Europe 101, between the straits of Gibraltar and the North Cape of Norway. The results of these observations, reduced under Dr. Whewell's superintendence, were published in the *Phil. Trans.* for 1836; and they are of great importance, not only as affording a far more precise determination of the progress of the tide wave and the forms of the cotidal line on the coasts of Europe and North America than had previously been attained, but as furnishing more correct data for the construction of the tide tables. (*Phil. Trans.* for 1842, 1843, and 1845, memoirs by Mr. Airy on the Laws of the Tides at Ipswich and Southampton, in the River Thames, and on the Coasts of Ireland.)

Influence of Atmospheric Pressure and Winds.—Besides the numerous causes of irregularity depending on local circumstances, the tides are also affected by the state of the atmosphere. At Brest, the height of high water varies inversely as the height of the barometer, and rises more than eight inches for a fall of about half an inch of the barometer. At Liverpool, a fall of one-tenth of an inch in the barometer corresponds to a rise in the river Mersey of about an inch; and at the London Docks, a fall of one-tenth of an inch corresponds to a rise in the Thames of about seven-tenths of an inch. With a low barometer, the tides may therefore be expected to be high, and vice versâ. The tide is also liable to be disturbed by winds. Sir J. Lubbock states that, in the violent hurricane of January 8, 1839, 'there was no tide at Gainsborough, which is twenty-five miles up the Trent—a circumstance unknown before. At Saltmarsh, only five miles up the Ouse, from the Humber, the tide went on ebbing, and never flowed till the river was dry in some places; while at Ostend, towards which the wind was blowing, contrary effects were observed. During strong north-westerly gales the tide marks high water earlier in the Thames than otherwise, and does not give so much water, whilst the ebb tide runs out late, and marks lower; but upon the gales abating, and the weather moderating, the tides put in, and rise much higher; whilst they also run longer before high water is marked, and with more velocity of current; nor do they run out so long or so low.' (*Elementary Treatise on the Tides*; Airy's 'Treatise on Tides and Waves,' *Ency. Metrop.*)

Tie. In Architecture, a piece of timber or metal placed in any direction, for the purpose of binding two bodies together which have a tendency to separate or diverge. [Roof.]

Tie. In Music, a character ⌣ used to connect notes which are divided by a bar, and

which are nevertheless intended to be joined together and sounded without any break.

Tiemannite. A name for the mineral Onofrite, after the discoverer Tiemann.

Tier. The battery of guns on one side of a ship's deck. *Cable-tier* is the place below where the cable is coiled: also the hollow space in the midst of the coil.

Tierce (Fr. tiers, Lat. tertius). In Heraldry, a term used for the field when divided into three parts.

Tiern. [LAIRD.]

Tiers État (Fr.). The third branch, or commonalty, in the French Estates. The origin and meaning of the word are illustrated by M. Gautier. (*Mém. de l'Acad. des Inscr.* vol. xxxvii.) Down to the time of the great French revolution, the French were divided into three distinct classes, the nobles, the clergy, and the commonalty, forming in their united capacity the states-general of the kingdom: and their deliberations were separately conducted by individual vote in different chambers, in which the three classes respectively assembled. They then met in common to deliberate together, and vote collectively. Now, as the number of the deputies was nearly equal in each order, the result of the votes taken collectively was always necessarily favourable to the privileged orders. Hence it was loudly demanded that the number of the third estate should be doubled, and the definite resolutions decided by individual instead of collective votes. It was owing to the refusal of the nobles and the clergy to comply with this demand, that the crisis of the French revolution was accelerated. [ASSEMBLY.]

Tiger (Lat. tigris, from a Persian word signifying *an arrow*). A species of the genus *Felis*, as large as the lion, but with a rounder head and longer body; of a bright reddish fawn colour above, a pure white below, irregularly crossed with black stripes. It is clothed with short hairs, and has no mane. The tiger is the most formidable and cruel of all quadrupeds, and the scourge of the less inhabited parts of India. It is limited to the Asiatic continent. [FELIS.]

Tiger Wood. The heartwood of *Machærium Schomburgkii*, a valuable cabinet wood obtained from British Guiana.

Tikor. An Indian name for the tubers of *Curcuma leucorrhiza*, as well as for a kind of arrowroot prepared from the tubers.

Til or **Teel.** The Indian name for *Sesamum orientale* and *S. indicum*, the seeds of which are commonly known as Til-seed. The black-seeded variety is Kala-til; the white-seeded, Suffed-til. Ram-til is the seed of *Guizotia oleifera*.

Til Wood. The timber of *Oreodaphne fœtens*, which has a foul smell.

Tile-ore. An impure oxide of copper, of a brick-red or reddish-brown colour. It is an earthy variety of Red Copper, mixed with variable proportions of hydrous oxide of iron or Limonite, and is found at Huel Edward, and in several of the Cornish mines near Redruth.

Tiles, Encaustic. A species of tiles with ornamental figures of different coloured clays indented on their surfaces. Such tiles were much used by the architects of the middle ages. The art of manufacturing them was revived about the year 1833 by Mr. Wright of the Staffordshire potteries, and soon after that time the manufacture was perfected by Minton. A good buff colour and a warm red are produced by firing certain clays in their natural state. Black is produced by staining with manganese, blue by staining with cobalt. The clays, after having been well washed and purified, are passed through lawn sieves in the liquid or *slip* state, as it is technically termed; and when brought to the right consistence, the clay intended to form the body of the tile is pressed into an iron mould, the bottom of which is formed of a plaster of Paris pattern bearing the design to be impressed on the tile. The pattern being removed, the indentations are filled with the coloured clays according to the intended design, and the surface is then shaved off so as to remove all superfluities and ruggedness, leaving the pattern intact. The tile is then dried for two or three weeks, and is finally fired by exposing it to an intense heat for sixty hours.

Tilestone. The name given in Geology to a well-marked series of hard finely laminated micaceous and quartzose sandstones and shales forming the top of the Silurian series in Caermarthenshire and the adjacent counties of Wales. The beds thus named occupy the highest part of a bold escarpment, 1,500 to 1,600 feet above the sea. They are in some places rich in fossils agreeing with those of the underlying Silurian deposits, and in many localities are quarried for excellent flags used in roofing. The corresponding beds in Cumberland and the Lake district possess excellent slates, but the typical tilestone has only flags, though these exhibit fair cleavage and are very finely laminated.

The tilestone was long regarded as at the base of the Old Red Sandstone series. Its position among the Silurians is now fully recognised.

Besides the tilestone of the Silurian period, there are many instances of fissile stones capable of being used for roofing obtained from rocks of various geological periods.

Tilia (Lat. *the lime-tree*). A genus of large-growing deciduous trees representing the order *Tiliaceæ*, and entirely confined to the temperate countries of the northern hemisphere. They have alternate heart-shaped leaves, and small yellowish highly fragrant flowers, borne in axillary cymes, which have a curious long leaf-like bract attached to their stalks.

The Common Lime or Linden, *T. europæa*, attains a height of from sixty to a hundred and twenty feet. It is found throughout the whole of Europe, except the extreme north, one small-leaved variety being indigenous to

Britain. The large-leaved variety commonly planted is, however, a native of the south of Europe. Various parts of this tree are applied to useful purposes. The white, soft, but close-grained wood is used by carvers and turners, and by musical instrument makers for sounding-boards. The tough inner bark is called *bass* or *bast*, and is the material of which the Russian mats used by gardeners and upholsterers are made; the Russian peasants also make shoes, ropes, nets, and other articles with it. The sap yields sugar, and the flowers an abundance of honey, of which bees are fond.

Tiliaceæ (Tilia, *the linden* or *lime tree*). A natural order of hypogynous Exogens, very nearly allied to the Malvaceous order, from which they differ in the stamens being distinct. They consist of trees or shrubs, rarely herbs, with alternate stipulate leaves, and usually cymose flowers, and are chiefly characterised by a valvate calyx, indefinite hypogynous stamens, and a free ovary divided into several cells, with the placentas in the axis. The calyx connects the order with *Malvaceæ* and *Sterculiaceæ*, from which it is distinguished chiefly by the stamens. The species are numerous, especially within the tropics. In useful qualities they resemble the *Malvaceæ*, their bark being tough, their sap mucilaginous, and their timber light. Russia mats are made from the tough inner bark of the common Lime-tree [Tilia], and *Corchorus olitorius* is employed in India as a potherb. A few have gay flowers, but the majority are plants of little interest to gardeners.

Tilkerodite. This name is applied to those varieties of Clausthalite in which part of the lead is replaced by cobalt. The name has reference to the locality (Tilkerode in the Harz) where the mineral is found.

Till. A widely spread clayey mass belonging to the newer part of the drift period, and composed generally of more angular blocks than the fresh-water marls and gravels of the newest part of the same period in the south of England. Parts of the till are known as the Boulder Clay. In one form or other, rocks of this age extend over all parts of northern Europe. They do not generally contain many fossils, though now and then both shells and bones are found in them. [Drift.]

The name *till* was originally given in Scotland to a particular deposit, for the most part unstratified, containing blocks of stone of all dimensions, mixed with mud, sand, and clay. Among the blocks, some are rounded, but most of them are angular, and their average dimensions increase as we advance northwards. The thickness of this deposit is sometimes a hundred feet, and it seldom contains organic remains of any kind. There can be little difficulty in referring this deposit to the glacial period. It must have been formed when Scotland was under water, and when icebergs drifted down from the polar seas, to be stranded on shoals, there leaving the accumulation of mud and stone derived from higher latitudes.

Occasional passages can be found from the *till* to stratified clay, gravel, and sand, occasioned perhaps by the sorting action of the water on the confused mass originally deposited, and by the action of marine currents intervening at certain seasons.

Tillage of Land. The relations of population to the cultivation of the soil will be determined partly by the occupation of the soil, and in part by the rate of production from the soil. The soil of a given country, again, may be partly unoccupied, sometimes from the fact that the needs of the population may not have imposed the obligation of cultivating inferior soils, or all soils of equal natural fertility but of unequal convenience or proximity to human habitations, as in newly settled countries; sometimes, from the fact that agricultural science is so imperfectly developed that much which at one time might be available has not hitherto been turned to any economical use, as in the middle ages. Again, the land of a given country may be generally occupied and tilled, but the rate of production may be very scanty, either because the soil is naturally defective in some of those elements which are necessary for abundant produce (as in mountainous countries), or if some of those appliances are wanting, out of which the rate of production may be largely increased (as was the case before the discovery of artificial grasses and saccharine roots). All these various states might be more fully illustrated and compared with that condition in which (the highest skill and security, and the most intelligent labour, being superadded to natural fertility) the maximum of population is maintained on the minimum area of tillage. This state of things is never, of course, attained, and, as all science is progressive, is not in fact attainable, though perhaps under some circumstances the limit of productiveness is nearly reached; and it should be added, that however extended may be the sphere of practical science, its economical application can never be commensurate, unless all political and social freedom—by which we must understand the extension to each man of all rights which do not trench on the rights of other men—is fully and permanently attained. The agricultural science, such as it was, of Cato, Virgil, and Columella did not save Italy from dissolution, and the old world from barbarism, because the Roman empire suffered under a military despotism, and added to the political evils of the empire the debasing and retrograde influences of slavery.

It is clear, when any given country imports no food from abroad, or none of any importance or regularity, that the amount of population will be limited to the numbers which can be maintained on the produce. If agriculture be greatly developed, if the rate of production be high, and mechanical arts are largely substituted for manual labour, the number of persons not engaged in tilling the soil will be great; and, conversely, when mechanical science is ill understood or not applied, when the rate of production is scanty, and the arts of agri-

culture are undeveloped, the number of persons who can be spared from the cultivation of the soil is very small, manufactures are imperfect, and foreign trade is scanty. The former of these conditions characterises in a general way the present social state of England; the latter represents its state in the middle ages. It should be remembered, also, that the arts of agriculture imply the production and improvement of stock, as well as the growth of corn, and that the food of cattle is only second in importance, as far as regards the economy of husbandry, to the supply of bread for man.

It is probable that, five hundred years ago, the amount of arable land in England was not much less than it is at present. It is true that large areas have been enclosed and cultivated within the last 150 years. The first enclosure Act (Ropley in Hampshire) was passed in the reign of Queen Anne. But much land which was once under the plough has been built on, much has been turned into park and pleasure ground, not a little has been lost by the encroachments of the sea or by subsidence of land; while the accretions due to the upheaval of land or the retrocession of the sea do not seem to be equal in quantity, still less equal in value. But it is clear that the amount producible annually from the soil of England and Wales five centuries ago could not have been sufficient for the maintenance of more than two millions of people.

In the first place, the rate of production in grain was very low. Eight bushels to the acre of wheat, i.e. four times the seed sown, was a good crop in a plentiful year, and was, it seems, very rarely exceeded. At present, thirty bushels may be taken as a fair crop on average wheat land. Crops of barley and oats, though generally larger in quantity than in the case of wheat, were, compared with the produce of modern times, proportionately scanty.

Our forefathers knew absolutely nothing of those saccharine roots which play so important a part in the economy of a farm. Turnips, carrots, and parsnips, and of course potatoes, were unknown. The first three of these were imported into England (it would seem from Holland) at or about the beginning of the seventeenth century. Potatoes, as is well known, were brought from North America towards the end of the fifteenth century. It will be plain, however, that in the total absence of those roots, comparatively few cattle and sheep, and those generally in poor condition, could have been maintained. Indeed, the practice was to kill at about the middle of November all cattle and sheep which could not well be kept through the winter, and salt them as winter provisions. The remaining stock was half-starved, and could never have been in prime order. Hence fat was four times the price of meat.

Again, the English farmer in the middle ages had no knowledge of artificial grasses. At the present time it is very hard to say which of our grasses are native, but it is generally believed that few of the best kinds are indigenous. The clovers, of course, are of foreign origin. Hence upland hay was very poor, and natural water meadow, though it supplied the most valuable and abundant hay, was deficient in saccharine or fat-producing elements; and further, the want of root and artificial grass crops necessitated fallows, for in the absence of stock, land could not be sufficiently manured for the purposes of a continuous rotation.

With little more than a fourth as much wheat as is now sown, with one-fourth less wheat-bearing land (if we admit that an equal amount of land was devoted to the plough) owing to the system of fallows, with no root crops and artificial grasses, with cattle small and weak, sheep light and half-starved, it does not seem likely that the population could have been more than a tenth of the number now maintained on English produce. It might very well be less, and instead of being two millions, it may have been no more than one and a half.

The cultivation of the soil was attended with great expenses. The horses, it seems, were very small, the oxen light. The rude ploughs merely scratched the ground, while iron and all iron implements were excessively dear. The price of iron five hundred years ago was not less than 8*l.* a ton in money of the time, i.e. was worth 24*l.* in silver, and if we estimate the general rise in the value of silver, as deduced from the prices of corn and other necessaries at those times, would in modern money at modern values cost 72*l.* the ton. So great a charge in the raw material from which agricultural implements were made must have been a serious hindrance to the progress of agriculture. The rent of good arable land was seldom more than 6*d.* an acre, i.e. when interpreted by the same standard, 4*s.* 6*d.* in modern value, and after the great plague of 1348 fell considerably below this amount.

For further information as to the state of agriculture in England during the period referred to, the reader is referred to *The History of Agriculture and Prices in England*, by Professor Rogers; for the amount of population at the conclusion of the seventeenth century (when agriculture had made great progress), to the works of Davenant and Gregory King; for the eighteenth century, to those of Arthur Young; and for the later facts, to Porter's *Progress of the Nation*, and the classification of occupations in the Census reports.

Tillandsia (after Prof. Tillands, of Abo). A genus of *Bromeliaceæ*, consisting of tropical and extra-tropical American herbaceous plants, growing frequently on trees, and covered with scurfy scales. Some of these plants serve as natural reservoirs for water in their native forests. The water flows down the channelled leaves, which are dilated at the base, so as to form a bottle-like cavity capable of containing a pint or more, and travellers tap these vegetable pitchers for the sake of the fluid which they contain. *T. utriculata*, a native of Jamaica, and many others have this property of storing

water. Dr. Gardner, in his *Travels in Brazil*, relates that a certain species of *Utricularia* grows only in the water collected in the bottom of the leaves of a large *Tillandsia*. The aquatic plant throws out runners, which direct themselves to the nearest *Tillandsia*, and there form new plants. In this way, several *Tillandsias* may sometimes be seen connected together.

T. usneoides, a native of the West Indies and the Southern States of America, hangs down from the trees like a tuft of long grey hair, much like certain lichens (*Usnea*) in European pine-forests. The trees in some parts of Central America have a strange gaunt appearance, from the profusion of this *Tillandsia* growing from their branches. The plant is collected, and steeped in water in order to remove the outer cellular portion, and the fibrous portion is then employed in place of horsehair to stuff cushions, mattresses, &c.

Tiller. In Naval language, the lever placed in the head of the rudder to turn it, and in a ship worked by the wheel.

Tilmus (Gr. τιλμός, from τίλλω, *I pluck*). Picking of the bed-clothes, or floccitation; a symptom of the fatal termination of some disorders.

Tilt (A.-Sax. teld). A small awning over the stern-sheets of an open boat.

Timber (A.-Sax.). In Commerce, wood used for building purposes. In a country like ours, which is very densely peopled, the supply of wood for building and naval purposes falls far short of the demand, and it is necessary that the deficiency should be met by foreign importation. This necessity is met by the abundant forests of Sweden and Norway, Russia and Canada.

Timber was originally liable to small and uniform duties. But during the great continental war and the unfortunate administration of Mr. Vansittart, whose financial policy was a continual series of extravagant errors, the Canadian lumberers and some shipowners induced the government to establish discriminating duties on Russian and other Baltic produce. The duties on Canadian timber were reduced, and in 1809 all but repealed, while that on Baltic timber was doubled. This action might have been justified on the miserable plea of retaliation. But after Napoleon's disastrous retreat from Moscow, and the restoration of English navigation to the Baltic, a further addition of 25 per cent. was laid on European timber, and ultimately, in 1819, the tax was fixed at 3*l.* 5*s.* the load of 50 cubic feet.

A tax on timber is in the highest degree inexpedient, because it is, in the first place, a tax on raw material, and such taxes multiply themselves in manufactured goods, and involve inevitably a greater loss to the public than they bring gain to the exchequer; and, in the next place, it is a tax on a commodity which, being in some degree produced at home, raises the price of home-grown timber by the full amount of the tax, and therefore charges the public with the enhanced price over all the timber *used*, while the government obtains the tax only over all the timber imported. But a discriminating tax on timber is even more indefensible, particularly since the kinds which come lightly taxed (those, namely, from Canada) are vastly inferior to those which were overtaxed (those, namely, from the Baltic). The effect of the duty was to compel the public to pay a high price for an inferior article.

The differential duties on timber, having been considerably modified in 1851, were equalised in 1860, and altogether repealed by the budget of 1866. Since 1858 the consumption of foreign timber has increased enormously.

It may be added, that when timber is sawn into pieces not above seven inches broad, the article is called *battens*; when above that breadth, *deals*. The term *wood* is used generally also to include ornamental timber and even dye stuffs.

Imports of Timber for the Seven Years ending with 1865.

Timber and Wood	1859	1860	1861	1862	1863	1864	1865

Timber. This term in a Legal sense includes in all cases oak, ash, and elm; but other trees (as, for instance, beech or birch) may be timber by the custom of particular counties or districts. (Craig *On Trees*.)

Timbers. In Shipbuilding, the ribs on which the vessel is framed. Each comprises (reckoning from the keel) the cross-piece, or half-floor, the several futtocks, the top-timbers, and, if necessary, the lengthening pieces. At the top, the timbers are all capped by the rough-tree-rail; below they are mortised on to the keel.

Timbre (Fr.). A word borrowed from the French, and used in Acoustics to signify the quality of a musical sound, termed by the Germans klangfarbe, *sound-tint*. When precisely the same note is sounded on two different musical instruments, say a pianoforte and an organ, although the *pitch* of the note, i.e. the number of vibrations per second, is the same in both, yet the two sounds are quite distinct. This distinction is due to a difference in the *timbre* of the two notes. The Germans express this by saying the sound has a different colour or tint in the two cases. This peculiar quality in musical sounds is caused by the mingling of a series of secondary tones with the primary one. When, for example, the string of a pianoforte is struck, the string, whilst vibrating as a whole, is at the same time divided, and again subdivided, into aliquot vibrating segments, which, as it were, ride on the back of the principal vibration. These vibrating subdivisions give rise to a series of higher notes, of gradually lessening intensity, called the *harmonics* of the primary note. The character and number of these harmonics coexisting with the principle note, is the cause of the timbre or quality of sound peculiar to different musical instruments. For the greater part of our knowledge of this subject we are indebted to the admirable researches of Prof. Helmholtz, a clear exposition of which, with much additional information, will be found in Prof. Tyndall's work *On Sound*.

Timbrel (Span. tamboril, Fr. tambour). In Music, a kind of drum or tabor, used from a very remote age.

Time (Fr. temps, Lat. tempus, literally *a portion*, from the root of the Gr. *τέμνω, I cut*). A limited portion of duration, measured by certain conventional or natural periods, and often marked by particular phenomena, as the apparent revolution of the celestial bodies, more especially of the sun, or the rotation of the earth on its axis.

Absolute Time is time considered in itself without reference to that portion of duration to which it belongs, however noted or marked.

Relative Time is time considered with reference to the termini of some specific interval of duration.

Apparent Time is time deduced from observations of the sun, and is the same as that which is shown by a properly adjusted sundial.

Mean Time is the time shown by a well-regulated clock; and would be the same as that shown by the sun, if the sun were always in the equator and his apparent diurnal motion in the heavens were uniform.

Sidereal Time is the portion of a sidereal day which has elapsed since the transit of the first point of Aries. It represents at any moment the right ascension of whatever object is then upon the meridian.

Astronomical Time of Day is the time past *mean noon* of that day, and is reckoned on to twenty-four hours in mean time.

Civil Time is mean time adapted to the purposes of civil life. The day commences at the midnight preceding the noon of the day, and is divided into parts of twelve hours each, the first twelve marked A.M. or *ante meridiem*, and the second P.M. or *post meridiem*.

TIME. In Metaphysics. [SPACE, NUMBER, AND TIME.]

TIME. In Music, this word has several significations.

1. It refers to the length of the different kinds of notes, a description of which is given in the article MUSIC.

2. It refers also to the number and arrangement of the notes in each bar or measure, which is always indicated by certain figures or signs at the commencement of the piece. Thus, a piece is said to be in *common* or *triple time*, as the primary division of the measure is into two or three parts, and so on. [MUSIC.]

3. It refers also to the *uniformity* of velocity throughout the piece; a performer who plays equal notes with unequal lengths being said not to *keep time*.

4. The word also refers to the *absolute* velocity with which music is played: thus, we say, a piece is in *quick*, or in *slow*, or in *moderate time*. The time in which a piece should be played, is indicated by Italian words placed at the commencement of the piece, some of which, however, are only figuratively expressive of time, their real meanings referring more to style; the following are the words most commonly in use for this purpose, beginning with the slowest:—

Grave: *grave, heavy*.
Lento: *slow*.
Largo: *broad*.
Larghetto: diminutive of *largo*.
Adagio: *leisurely*.
Andante: *going*.
Andantino: diminutive of *andante*.
Allegretto: diminutive of *allegro*.
Allegro: *joyfully*.
Con moto: *with movement*.
Vivace: *lively*.
Presto: *quick*.
Prestissimo: *very quick*.

The words più (*more*), meno (*less*), or poco (*little*), added to these, affect their significations accordingly.

The time in which music should be taken has of late years been generally indicated by the METRONOME.

Timocracy (Gr. τιμοκρατία). A term made use of by some Greek writers, especially Aristotle, to signify a peculiar form of constitution; but there are two different senses in which it is thus used, corresponding to the different meanings of the word τιμή, *a price* or *honour*, from which it is derived. According to the first, it represents a state in which the qualification for office is a certain amount of property; in the latter it is a kind of mean between aristocracy and oligarchy, when the ruling class, who are still the best and noblest

citizens, struggle for pre-eminence amongst themselves.

Tin (Ger. zinn, Fr. étain, Lat. stannum). This metal, the Jupiter (♃) of the alchemists, is represented by the symbol Sn (stannum) and by the equivalent 59. It has been known from remote ages, and is said to have been obtained at a very early period from Spain and Britain by the Phœnicians. It occurs most abundantly in Cornwall, the mines of which afford about 3,000 tons annually: it is also found in Germany, Bohemia, and Hungary; in Chili and Mexico; in the peninsula of Malacca; and in India, in the island of Banca. The *native peroxide* is the principal *ore of tin*: the metal is obtained by heating it to redness with charcoal or culm, and a little lime; the first product is impure, and is returned into the furnace, and carefully heated so as to fuse the tin, which runs off into an iron kettle, while the principal impurities remain unmelted; in the kettle the tin is kept in fusion, stirred, and agitated by plunging billets of green wood into it. The impurities thus collected upon the surface are removed by a skimmer; and the metal is then cast into blocks of about 3 cwt. each. The common ores, known under the name of *mine tin*, furnish a less pure metal than that obtained from *stream tin*. The purest tin is known under the name of *grain tin*, a term formerly applied exclusively to the metal obtained from the stream ore: *block tin* is less pure, and is the produce of the common ore. The peculiar columnar fracture which pure tin exhibits when broken, is given by heating the ingot till it becomes brittle, and then letting it fall from a height upon a hard pavement.

Tin has a silvery-white colour with a slight tint of yellow, and when so viewed as to exclude the white light reflected from its surface, it is decidedly yellow: it is softer than gold, but harder than lead: it is malleable, though imperfectly ductile. What is termed *tinfoil* is the metal beaten out into thin leaves, but it is seldom pure and the common commercial article generally contains from 30 to 40 per cent. of lead. The foil frequently used for packing articles of food, confectionery, tea, &c. is lead thinly plated with tin, and is more easily oxidised than the separate metals, so that it may in some cases give rise to lead-poisoning. Traces of arsenic are also not uncommon in it. The sp. gr. of tin fluctuates from 7·28 to 7·6, the lightest being the purest metal. When bent, it occasions a peculiar crackling noise; and when rapidly bent backwards and forwards several times successively, it becomes hot, a circumstance due to the friction between the crystals. When rubbed, it exhales a peculiar odour. It melts at 442°, and slightly contracts on consolidation. By exposure to heat and air it is gradually converted into protoxide (SnO); but if the heat be continued till metallic tin no longer remains, the protoxide passes into peroxide (SnO_2). Placed upon ignited charcoal under a current of oxygen gas, it enters into rapid combustion, forming the peroxide; and if an intensely heated globule of the metal be thrown upon a sheet of dark-coloured paper, it subdivides into small particles, which burn very brilliantly and leave lines of white oxide. It volatilises at a very high temperature. When a polished surface of tin is heated, it becomes yellow and iridescent, in consequence of superficial oxidation. A preparation, under the name of *powdered tin*, is sometimes made by shaking the melted metal in a wooden box rubbed with chalk on the inside. The substance called *tin putty*, used for polishing plate, is made by levigating the crusts of oxide that form on melted tin.

Protoxide of Tin; *Stannous Oxide* (SnO).—This product is obtained by precipitating a solution of protochloride of tin by ammonia; it falls in the state of *hydrate*. It is obtained *anhydrous*, by heating it in a glass tube, passing a current of dry carbonic acid over it till the water is carried off, and suffering it to cool out of the contact of air. The specific gravity of this oxide is 6·6. It forms a dark-grey or black powder, which, on the contact of a red-hot wire, burns like tinder into peroxide. In the hydrated state it dissolves readily in sulphuric, hydrochloric, and dilute nitric acids, as well as in caustic potash and soda, but not in ammonia, nor in the alkaline carbonates.

When a solution of protochloride of tin is mixed with moist hydrated sesquioxide of iron and boiled, an interchange of elements takes place, by which protochloride of iron and sesquioxide of tin are formed: $2SnCl + Fe_2O_3 = Sn_2O_3 + 2FeCe$. This oxide in ammonia is distinguished from protoxide by its solubility, and from peroxide by its giving a purple precipitate with chloride of gold. It is soluble in concentrated hydrochloric acid. It may be represented as a stannate of the protoxide, by the formula SnO, SnO_2.

Peroxide of Tin; *Binoxide of Tin* (SnO_2).—This is the common ore of tin: in its crystalline form it is insoluble in acids, but when heated with potash or soda it forms a soluble compound. There are two remarkable varieties of the hydrate of this oxide, which have been distinguished as *stannic* and *metastannic acid*. *Stannic acid* (SnO_2, HO) is obtained by precipitating a solution of bichloride of tin by ammonia, and washing and carefully drying the precipitate: it is soluble in acids, and in solutions of potash and soda, but not in ammonia. When heated to about 300°, it passes into metastannic acid. *Stannate of Potash* is formed when peroxide of tin is heated with potash. *Stannate of soda* (NaO, SnO_2, 4 HO) may be similarly prepared and crystallised: it is largely used as a mordant by dyers and calico-printers.

Metastannic acid is the result of the action of nitric acid upon tin: in its most concentrated form nitric acid does not immediately act upon tin, but on the addition of a few drops of water violent effervescence ensues, much heat is evolved, together with nitric oxide and nitrous acid vapour; some nitrate of ammonia is also

formed; and the metastannic acid remains in the form of a white insoluble powder: it may be purified by washing, and dried at a dull red heat. When dried in the air it consists of Sn_5O_{10}, 10HO: dried at 212° it loses 5HO, and at a red heat becomes anhydrous, and acquires a pale buff colour. Hydrated metastannic acid is insoluble in nitric acid: it dissolves in sulphuric acid, forming a compound soluble in water, but decomposed by boiling. It dissolves in solutions of potash and soda, and their carbonates, but not in ammonia, The *metastannates* are not crystallisable.

Native Peroxide of Tin is generally grey, brown, or black, and sometimes transparent or translucent; its specific gravity is 7: its primitive crystal is an obtuse octahedron, of which there are very many modifications. In some of the valleys of Cornwall it is found in nodules mixed with pebbles, and is called *stream tin*. A modification of stream tin, in small banded fragments or globular masses, is called *wood tin*.

Protochloride of Tin (Sn Cl) is obtained by subjecting a mixture of 1 part of tin filings and 2 of corrosive sublimate to distillation. When tin is dissolved in hydrochloric acid, the solution evaporated, and the dry residue carefully heated to incipient redness in a small tube retort, so as to exclude air, the protochloride of tin remains nearly pure. It is in the form of a grey solid, fusible and volatile at a high heat (*butter of tin*). When its solution in a small quantity of water is evaporated, it yields prismatic crystals, which include 3 atoms of water. The protochloride of tin, or *salt of tin* of commerce, is made by putting 1 part of granulated tin into a basin upon a sand-bath, and pouring upon it 1 part of hydrochloric acid; after some hours 3 parts more of the acid are added, and the mixture stirred and digested till a saturated solution is obtained. During the process, fetid hydrogen gas is given off, and the greater part of the tin is dissolved; when the clear liquor is poured off, it is set aside to crystallise; the mother liquors are again evaporated as long as they afford crystals, and the residue is afterwards employed for conversion into bichloride.

With solution of gold, this protochloride produces a purple precipitate used in painting porcelain, under the name of PURPLE OF CASSIUS. With infusion of cochineal, it produces a purple precipitate; and it is much used to fix and alter colours in dyeing and calico-printing.

Perchloride of Tin ($SnCl_2$).—If tin is heated in excess of chlorine, or if a mixture of one part of tin filings and four of corrosive sublimate is distilled, the perchloride will pass over. It is a transparent colourless fluid, formerly called LIBAVIUS'S FUMING LIQUOR: it exhales copious fumes when exposed to moist air; and with one-third its weight of water it forms a crystallised hydrate = ($SnCl_2$5HO). A solution of perchloride of tin, much used by dyers, is made by dissolving tin in a mixture of two measures of hydrochloric acid, one of nitric acid, and one of water.

Bisulphide of Tin (SnS_2) is obtained as follows: Take 12 oz. of tin and amalgamate it with 6 oz. of mercury; reduce it to powder, and mix it with 7 oz. of sublimed sulphur and 6 oz. of sal ammoniac, and put the whole into a glass matrass placed on a sand-bath. Apply a gentle heat till the white fumes abate, then raise the heat to redness, and keep it so for a due time. On cooling and breaking the matrass, the bisulphide of tin is found at the bottom. The use of the mercury is to facilitate the fusion of the tin and its combination with the sulphur, while the sal ammoniac prevents such increase of temperature as would reduce the tin to the state of protosulphide.

The extraordinary golden lustre of the bisulphide of tin, and its flaky texture, rendered it an object of great interest to the alchemists: it was termed *aurum musivum*, and *mosaic gold*. When well made, it is in soft golden flakes, friable and adhering to the fingers. It is used for ornamental work, under the name of *bronze-powder*, especially by the manufacturers of paper-hangings: it is chiefly imported from Holland and Germany.

Tin plate is a most useful alloy of tin and iron, in which iron plate is superficially alloyed with tin, and to the surface of which a quantity of tin further adheres, without being in combination. It is made by dipping cleansed iron plates into a bath of melted tin. An objection to such combinations is, that in consequence of the electrical relations of the metals, the iron, if anywhere exposed, has an increased tendency to oxidation: for although the surface of the tin itself is sufficiently durable, no sooner is any portion so abraded as to denude the iron, than a spot of rust appears and rapidly extends: hence the superiority of iron plate covered by zinc instead of tin, zinc being electro-positive, whereas tin is electro-negative in regard to iron, under the influence of common oxidising agents.

Moiré métallique is tin plate which has been superficially acted on by an acid, so as to display, by reflected light, the crystalline texture of the tin. [MOIRÉ MÉTALLIQUE.]

The *tinning of pins* is effected by boiling them for a few minutes in a solution of one part of a bitartrate of potash, two of alum, and two of common salt, in ten or twelve of water, to which some tin filings or fragments of finely granulated tin are added; they soon become coated with a film of tin, and are then taken out, cleaned, and dried. The pins are made of brass wire, and require to be perfectly clean before they are put into the tinning liquor. Tin medals, or casts in tin, are *bronzed* by being first well cleaned, wiped, and washed over with a solution of one part of protosulphate of iron, and one of sulphate of copper, in twenty of water—this gives a grey tint to the surface; they are then brushed over with a solution of four parts of verdigris in eleven of distilled vinegar, left for an hour to dry, and polished

with a soft brush and colcothar. [BLOCK TIN.]

Tin Plate. [TIN.]

Tin Pyrites. Native sulphide of tin, copper, and iron. It occurs, when pure, of a steel-grey colour, which, however, often inclines to brass-yellow owing to an admixture of Copper Pyrites, at Carn Brea and other Cornish mines, and also in the granite-veins of St. Michael's Mount.

Tin Stone. The common name for native oxide of tin or Cassiterite.

Tinca (Lat. *a tench*). A subgenus of Cyprinoid fishes, characterised by having short anal and dorsal fins; very short barbules or tentacles about the mouth; no bony serrated ray at the commencement of either the dorsal or anal fins; small scales. Like the rest of the Linnæan *Cyprini*, the *Tinci*, or tenches, have no teeth except in the pharynx; whence the name of *leather-mouthed fishes* applied to this family of *Pisces Abdominales*.

Tincal. The Oriental name for Borax.

Tincture (Lat. tinctura, from tingo, Gr. τέγγω, *to wet* or *moisten*). A Pharmaceutical preparation, generally consisting of active remedies dissolved in rectified or in proof spirit. Tinctures are generally made by digesting bruised or pulverised vegetable substances in spirit, either at common temperatures or aided by heat. Various ingenious inventions have been in use of late years, by which these tinctures are prepared and filtered without access of air. The term *tincture* is also applied to alcoholic solutions of resins, of which tincture of myrrh is an instance. Tinctures, from the quantity of alcohol which they contain, are necessarily exhibited in small doses: the most important are those which contain highly active ingredients, such as opium, &c.

Tinctures. In Heraldry, tinctures are of three kinds: metals, colours, and furs. The former are or, argent; the second gules, azure, sable, vert, purpure, sanguine, and tenny. The chief furs are ermine and vair; but there are several varieties of both, distinguished by different names. Each metal and colour, in blazonry (except the two last and least honourable, sanguine and tenny), is represented by a distinct precious stone and heavenly body; and when the arms of sovereign princes or high dignities are described by old heralds, the tinctures are frequently denoted by the names of these jewels or celestial bodies. [ARGENT; OR; &c.]

Tinder Ore. An impure arsenical sulphide of antimony and lead found in soft flexible flakes, resembling reddish tinder, at Andreasberg and Clausthal in the Harz.

Tinea (Lat. *a small worm* or *moth*). The scald head. [RINGWORM.]

Tinkalzite. A hydrous borate of lime and soda from Peru, which is used in the arts as a substitute for borax.

Tinkar's Root. The root of *Triosteum perfoliatum*.

Tinospora. A genus of *Menispermaceæ*, consisting of climbing Indian shrubs, with thickened jointed leafstalks and long axillary or terminal clusters of flowers. It has been remarked in reference to the extreme vitality of these plants, that when the main trunk is cut across or broken, a rootlet, speedily sent down from above, continues to grow till it reaches the ground and restores the connection. A bitter principle, *columbine*, pervades the species, many of which have tonic and emetic properties. An extract called *Guluncha* is considered to be a specific for the bites of poisonous insects, and for ulcers, and is prepared from *T. cordifolia* and *T. crispa*. It is administered as a diuretic and tonic in cases of fever, and is also employed in snake bites. The young shoots of *T. cordifolia* are used as emetics.

Tipstaff. A species of constable in attendance on the courts of chancery and common law, appointed formerly by the warden of the Fleet Prison and the marshal of the Queen's Prison, but now by the Lord Chancellor, the Lord Chief Justices, and the Lord Chief Baron respectively. (Stat. 5 & 6 Vict. c. 22.)

Tirailleurs (Fr.). Literally, men who shoot carelessly or at random, and hence denoting those individual soldiers, who, though firing at an object, were themselves scattered from the main body of troops, and did not fire together. The word is now used in the French army in the sense of *sharpshooters* or *skirmishers*.

Tirolite. [TYROLITE.]

Tironian Notes. The short-hand of Roman antiquity. According to the received story, they were introduced into Rome by Tiro, the freedman and favourite of Cicero: he is supposed to have imported the art from Greece. MSS., written entirely in what are called the Tironian notes, are not unfrequently of the date of the seventh century and downwards; and they are still common in marginal notes. (Kopp, *Tachygraphia Veterum Exposita*; Carpentier, *Alphabetum Tironianum*, 1747.) Tassin, in the third volume of his *Nouveau Traité de Diplomatique*, attempted, with more or less success, to decipher the Roman abbreviations. Some have thought that valuable lost classics may be recovered through this key; but as yet these hopes have been nugatory. (*Ed. Rev.* vol. xlviii. p. 357 &c.)

Tisane (Fr.; Gr. πτισάνη, *barley water*). A drink prepared in France from the flowers of *Malva sylvestris*.

Tisri. The first Hebrew month of the civil year, and the seventh of the ecclesiastical year. It corresponds to part of September and October.

Tissue (Fr. tissu). In animals, the substance of which systems of organs are composed, as e.g. bone, or *osseous tissue*, in the osseous system; flesh, or *muscular tissue*, in the muscular system; *neurine*, or nervous tissue, in the nervous system; *dentine*, or tooth-bone, in the dental system. The branch of Anatomy which treats of the tissues is termed HISTOLOGY.

Tissue. In plants, the thin membranous organisation of which every part is composed, microscopical in size, and often appearing to the naked eye homogeneous, although it consists of a great variety of forms closely compacted. Vegetable anatomists regard its primitive form as spheroidal, and maintain that the tubes and spiral vessels are mere extensions of that form. Tissue appears in all plants to be of the same nature originally, but it soon becomes altered by the deposition of various secretions upon its sides.

Titan (Gr.). In Greek Mythology, this word generally occurs in the plural number, and is applied to the children of Uranus and Ge. Among them was Cronos, the father of Zeus, and through him of the Olympian gods. (Hesiod. *Theog.* 133 &c.) The children of the Titans, as Atlas, Prometheus, &c., also retained the name. The Titans themselves, at the close of their war with Zeus, were thrust down into Tartarus. [THEOGONY.]

Titanite. Native oxide of titanium.

Titanium. A metal discovered by Gregor in a mineral from Cornwall called MENACCANITE. Its characters were first ascertained by Klaproth, who gave it the above name. In the year 1822, Dr. Wollaston ascertained the presence of a large proportion of titanium in the minute copper-coloured crystals occasionally found in the slag of the iron smelting furnaces at Merthyr and elsewhere. They are of a copper colour, almost infusible, of a specific gravity of 5·8, and so hard as to scratch not only glass but crystal. They resist the action of air and acids, but are oxidised by the action of nitre at a red heat. It has since been ascertained that these crystals contain about 18 per cent. of nitrogen and 4 of carbon, and are probably a mixture of nitride with cyanide of titanium. The equivalent assigned to titanium is 24, and the peroxide, or titanic acid, is TiO_2. Titanium appears susceptible of two degrees of oxidation. The protoxide is blue or purple, and appears to constitute the mineral called *anatase.* The peroxide exists nearly pure in *titanite,* or *rutilite,* and is combined with the oxides of iron and manganese in *menaccanite.* The properties of pure titanium are but little known.

Tithe (A.-Sax. teotha; the Scotch form is teinds). In Ecclesiastical Law, the tenth part of the produce of the land, which, in this and other Christian countries, was anciently set apart for the endowment of the church. The Levitical ordinance has frequently been appealed to under the Christian dispensation, as establishing the divine right of the clergy to the receipt of tithes for ever; but this ground of claim has been generally abandoned in modern times. The duty of paying tithes was first enjoined, apparently, in certain ecclesiastical canons, in the year 750; and the first civil decree upon the subject is discovered in the laws of Offa, king of Mercia, in 794. In France, a similar law was enforced by Charlemagne in 778, and from that time the payment has been continued without interruption to modern times.

Of tithes there are, or rather were, three kinds: 1. *Predial,* of the vegetable productions of the land, as corn, hay, &c.; 2. *Mixed,* as of wool, pigs, &c., which, though natural products, are nurtured and preserved by the care of man; 3. *Personal,* as of manual occupations, trades, fisheries, and the like. Another division of tithes is into *great* and *small,* or *parsonage* and *vicarage tithes*: of these, the former are chiefly corn, hay, and wood; the latter are predial tithes of other kinds, together with mixed and personal tithes. The great tithes belong to the RECTOR; whereas only the small tithes are due to the VICAR. By the original law, all the land of the country was titheable, excepting the property of the crown, and of the church itself. But when, at the Reformation, the monasteries were dissolved, and their estates granted for the most part to laymen, these lands would have become titheable again, but for a particular statute (31 Hen. VIII. c. 13) which was enacted for the advantage of the new possessors. It was also allowable, up to the 13 Eliz., to effect compositions between the clergy and owners of the land, by which the parish was discharged of these payments for ever, in consideration of lands made over to the parson in exchange. This practice was restrained by a statute passed in 13 Eliz. which limited all such compositions to a period of three lives or twenty-one years. From these causes, however, we find a great deal of land in the hands of lay proprietors not subject to this charge. The monasteries are said to have held one-third of the benefices of the kingdom, the tithes belonging to which they received, appointing members of their own body, as their vicars or curates, to discharge the ordinary functions of parochial ministers. To these they either gave fixed stipends, or allotted the small tithes, taking, as their own share, the great or rectorial tithes. This is called *appropriation* of tithes; but when these benefices fell into the hands of laymen, the same practice was continued, and is distinguished by the title of *impropriation.*

Lands and their occupiers might be discharged from the payment of tithes, either in part or totally, by a composition, or by custom or prescription.

Such is the general view of the law of tithe immediately previous to the great changes introduced by the Tithe Commutation Act, 6 & 7 Wm. IV. c. 71; the object of which was to convert a tax, imposed on the gross produce of the soil, and varying annually in amount as well as money value along with it, into a rent charge, perpetual as to the amount, but varying according to the money value.

By this Act the money value of the tithes in each parish was to be calculated according to the average of the seven years ending at Christmas, 1835, minus the expenses of collecting, &c.; but without deduction on account of parochial or county rates, &c. The com-

missioners appointed for that purpose under the Act were then to award that sum (subject to some unimportant allowances), as the amount of the rent charge to be paid in respect of the tithes. This rent charge was to be apportioned among the lands of the parish, having regard to their average titheable produce and productive quality. The rent charge, being thus valued in money, was to be taken as the price of such a quantity of wheat, barley, and oats as it would have purchased (each grain in equal quantities), according to the average price at the period of the confirmation of the apportionment. That quantity of grain was therefore to remain for ever as the annual charge upon the parish. In order to regulate the money amount of the tithes, the money payment each year was to be equal to the price of that quantity at the average of the seven years immediately preceding, to be ascertained by an advertisement of the comptroller of corn returns, published in the month of January every year. The rent charge was to be paid by the occupiers of the land on which it was apportioned.

According to the returns under the property tax (1810), it appeared that about 8,000,000 acres in England and Wales were tithe-free, and 21,000,000 titheable. Mr. M'Culloch's *Statistics of the British Empire* contains the following analysis of appropriations, &c. of tithes:—

Belonging to the crown	38
Archbishops and bishops	385
Ecclesiastical corporations aggregate	702
Dignitaries and other ecclesiastical corporations sole	438
Universities, colleges, and hospitals	281
Private owners	2,552
Municipal corporations (since sold)	43
Vicarages partly endowed	121
Ditto wholly endowed	132

TITHE. In Finance and Political Economy, a tax levied on produce, and strictly a *tenth* of the amount produced. The term is also used loosely for any proportionate quantity taken by way of tax and for such taxes as are intended for other purposes than those to which tithes are ordinarily devoted, viz. the maintenance of ecclesiastics and ecclesiastical buildings.

The economical effect of a tax on produce is not mischievous when agriculture is rude and land is unimproved by artificial means. The tax is a simple property tax, which takes in equal proportion from rich and poor soils. But when land is made capable of cultivation by a large outlay of fixed capital, as, for instance, by drainage, or by artificial irrigation, or by the superposition of vegetable soil upon a barren surface, a tithe is exceedingly unjust, since it taxes unequal capitals at equal rates. A tithe has therefore been always viewed by economists as a great hindrance to improvement, because it forms a tax on improvement, and where it has not been confiscated en masse, it has been commuted to a fixed rent charge. Such has been the change effected in this country.

Titienses. [EQUITES.]

Title. In Bibliography and Printing, the first page of a book, giving in a few lines—the fewer the better—a notion of the subject of the work. This page is usually left till the body of the work is completed, as circumstances may alter the author's intentions as to title, preface, date, dedication, &c. The sheet containing these parts of a book is marked for the binder by *signature* A, and, if more than a sheet, by a, b, &c. It is not, as Professor de Morgan observes, an easy or every-day matter to choose a good title for a book; and the difficulty is constantly increased by the increase in the number of books on any particular subject. A title-page is a matter of literary importance greater than most people imagine: priority of conception gave birth to the felicitous titles of the *Spectator*, the *Tatler*, and other early works; but later titles of essays of a similar kind, such as the *Idler*, the *World*, &c., are unfortunate. Jewish and Oriental authors were partial to allegorical titles, some of them remarkably puerile; but the Greeks and Romans showed considerable taste in the names of their books. Some of the English titles of the seventeenth century were in the worst taste, such as *The Sixpenny-worth of Divine Spirit*, Baxter's *Shove*, *A Pair of Spectacles for Sir Humphrey Lind*, *A Fan to drive away Flies*, &c.

Title to Property. It is obvious that the bare possession of property does not always indicate that the holder is entitled absolutely to dispose of it. The actual occupier of a house or land is in most cases only a tenant for years, and it very frequently happens that the landlord or the person assuming to act as owner of an estate has, in fact, only a life interest in it, or has mortgaged or otherwise encumbered it. It is therefore necessary, upon every sale or mortgage of lands, to investigate the title of the person who is about to convey, for the purpose of ascertaining as far as possible that he has a right to do so, and that the purchaser or mortgagee will, after he has parted with his money, be safe against disturbance by other claimants. The period for which a title is investigated is for the last sixty years, and every vendor of freehold property is bound to furnish the intended purchaser with an abstract of all the deeds, wills, and other instruments which have been executed with respect to the lands in question during that period, and to furnish proper evidence of deaths and other material facts. The precise term of sixty years is usually supposed to have been adopted, or at least continued, with a view to the ordinary duration of human life. For as long as the law allows land to be settled on a man for life, and after his death on his son, or some other remainder-man, so long must it be necessary to carry the title back to such a point as will afford a reasonable presumption that the first person mentioned

as having conveyed the property, was not a tenant for life merely, but a tenant in fee simple.

The case is different with respect to most kinds of personal property. Money and negotiable securities (such as bills of exchange, &c.) pass freely from hand to hand; and, in the case of theft or misappropriation, the true owner has no right to require restitution of his property from any innocent holder of it not privy to the offence. Ordinary merchandise or goods, if stolen, may in some cases be reclaimed by the rightful owner; but this risk is not sufficient to make it worth while, as a general rule, for a purchaser to ask any questions with respect to his vendor's title. As regards stock in the public funds and shares in public companies, a purchaser of them will be safe if he obtains a proper transfer from the person in whose name they are standing, unless he has notice that they belong to some one else. Stock and shares, and many other kinds of personal property, such as mortgage investments and the like, are frequently made the subject of settlements; but property of this nature (unlike real property) can be settled only through the medium of trustees, and when settled is usually treated as a temporary investment representing so much money, and is not, like a landed estate, intended to remain in specie in the same family. It is therefore the practice, in order to facilitate changes of investment, to give to the trustees of settled personal property the fullest powers of disposing of it without rendering it necessary for purchasers from them to investigate the title of the person beneficially interested. It happens, however, not unfrequently, that reversionary or other interests in personal property are sold or mortgaged by the beneficial owners before the time has arrived for an absolute division or apportionment of the settled funds, and under these circumstances an enquiry into the title becomes as necessary as in the case of real estate.

The necessity of a detailed enquiry into title is undoubtedly a great source of expense and delay in dealing with land; and with a view to remedy these evils an Act has been passed 'to facilitate the proof of title to, and the conveyance of, real estates.' (Stat. 25 & 26 Vict. c. 67.) Under this Act, an office for land registry has been established, in which landowners may submit their titles to official investigation, and have them registered in case they are approved of as good and marketable. Provision is made for the registration of land either with an indefeasible title, or with a title subject to specific incumbrances. And it is enacted that the persons described in the 'record of title to land on the registry,' as entitled to any land, are, subject to the specified qualifications or incumbrances, if any, and for the purposes of sales, mortgages, and contracts for valuable consideration, to be deemed absolutely and indefeasibly entitled to such estates, rights, powers, and interests, as shall be expressed on the record; the practical effect of which provision is that investigation and reinvestigation of the title on the occasions of *subsequent* sales, mortgages, &c., will become in a great measure unnecessary. The Act, however, is permissive only, and has not at present been made use of to any great extent. Between October 15, 1862 (when the office of land registry was opened), and June 10, 1865, there were 291 applications made for registration of titles, 43 of which (relating to property of an aggregate value of 622,050*l.*) had at the latter date been completed or were ready for completion, 35 had failed or been withdrawn, and the rest were still pending in the office. By a later parliamentary return, made up to March 10, 1866, it appears that up to that date the total number of applications under the Act had been 359, 114 of which (relating to property of a total value of 1,443,547*l.*) had been completed or were ready, and 53 had failed or been withdrawn.

Titmouse. [PARUS.]

Titular (Lat. titulus, *a title*). Chiefly in Ecclesiastical usage, a person invested with the title to a benefice: generally used for one who has the title only, without possession or enjoyment. The term, however, has been in some cases applied to the possessors of the property of suppressed bishoprics, &c.

Tiza. The name given to the native borate of lime (Hayesine) in Southern Peru.

Tjettek. A Javanese name for the virulent poison prepared from *Strychnos Tieuté*.

Tmesis (Gr. from τέμνω, *I cut*). In Grammar, a figure by which a compound word is separated into two parts by the intervention of one or more words, as in the following line of Terence, 'Quæ meo cunque animo lubitum est facere,' for 'quæcunque meo animo.' This figure is a license in the Latin language, frequent in Terence and Lucretius, rare in later writers; in the Greek it is more common; but of all Western languages, the German lends itself most readily to the division of compound words. In English the figure is unused.

Toad (A.-Sax. tade). The kind of tailless Batrachian, common in Britain, which exemplifies the family *Bufonina*, having half-webbed toes, the glandular swelling called *parotoid* between the eye and ear, and the sacral diapophyses expanded. The genus *Bufo* has the femur rather short; no teeth; tongue elliptical, entire, with the free margin turned back; skin more or less warty. Toads exist in almost every part of the globe except Australia. The parotoids exude a fetid and rather acrid milky secretion, which is the sole foundation for the vulgar error of the poison of the toad. The animal is useful to man, and in no way noxious.

Toad's-eye Tin. A pale hair-brown variety of Wood Tin found at several mines near Tregurthy Moor in Cornwall.

Toadstone (Ger. todtstein, *dead-stone*). The name given by miners to certain bands,

generally basaltic, which alternate with bands of limestone of the carboniferous series. It has been found by experience, that when metalliferous (lead-bearing) veins exist in these strata, the ore is rarely present where the vein traverses the basalts, and thus these rocks are said to be *dead*, as not being productive. This name is applied chiefly in Derbyshire. [CARBONIFEROUS LIMESTONE; TRAP-ROCK.]

Toadstools. The common name for various species of *Agaricus* and *Boletus*, common fungi, which, according to the notion of older herbalists, derived their origin from toads, as puffballs (*Lycoperdon*) derived theirs from wolves, or deerballs (*Elaphomyces*) from deer.

Tobacco. The dried leaves of the *Nicotiana Tabacum*, a plant indigenous to America, but which succeeds well, and is extensively cultivated, in most parts of the Old World. The recent leaves possess little odour or taste; but when dried, the odour becomes strong and peculiar, and their taste bitter and acrid. When distilled, they yield a volatile principle called *nicotine*, on which their virtue depends, and which is a virulent poison. There is also obtained a concrete volatile oil which appears to possess active properties.

The leaves are used in various ways, being chewed, smoked, or ground and manufactured into snuff. It is in the last-mentioned form that tobacco was, till of late years, principally used in Great Britain. Much discussion has arisen of late years respecting the practice of smoking tobacco, it having been argued, on the one hand, that the custom is invariably injurious, and that the nervous system suffers materially even in those who indulge in a moderate degree. On the other hand, smokers urge the fact that the practice can scarcely be injurious, inasmuch as it cannot be shown that smoking interferes with longevity, and that many men of high intellect have been inveterate smokers and have lived to a good old age. The subject has been treated by the late Sir Benjamin Brodie and by Mr. Solly. The former does not consider smoking in moderation more injurious than the moderate use of wine, though he highly disapproves of the excessive use of tobacco. Mr. Solly takes a strong view, and believes all use of tobacco injurious.

The term *tobacco* is probably derived from Tobaco, a province of Yucatan, where it was first found by the Spaniards. To Sir Francis Drake and Sir Walter Raleigh has been ascribed the honour of having introduced it into England, nearly three centuries ago.

Tobago Canes. A name under which the slender trunks of *Bactris minor* are sometimes imported into Europe, to be made into walking-sticks.

Tocsin. An old French word, of which the derivation seems not to be ascertained: Gregory of Tours uses the word *seing* for the sound of a bell (*Ency. Méthodique*), signifying an alarum-bell (Ger. sturmglocke). The use of the tocsin, during the troubles of the Revolution, to assemble the multitude, has rendered the word almost proverbial.

Tocusso. An Abyssinian corn-plant or millet, bearing the scientific name of *Eleusine Tocusso*.

Tod. A weight used in weighing wool. It contains twenty-eight pounds avoirdupois.

Toddy. The juice which flows from the spathes of *Borassus flabelliformis*, *Raphia vinifera*, *Mauritia vinifera*, *Arenga saccharifera*, the cocoa-nut, date, and other palms, when they are cut or wounded. This juice forms Palm wine. It is a delicious beverage when fresh, and is employed in India by bakers instead of yeast in the preparation of bread; it is also extensively distilled into a spirituous liquor, generally drunk by the natives, among whom it is known by the name of *bowra*.

Tods' Tails. A Scotch name for the common Highland Clubmosses.

Toffs. The fragrant flowers of the North African *Rhaponticum acaule*.

Toft. An Anglo-Saxon word, denoting strictly the tuft of trees sheltering a homestead, and sometimes surrounding it. In old deeds it is commonly joined to *croft*, another Anglo-Saxon word meaning an enclosed field.

Toga (Lat.). The gown or mantle peculiar to the Roman people; whence it was sometimes designated as the *gens togata*, or toga-clad nation. The toga was a loose flowing woollen garment covering the whole body round, close below, but open at the top down to the girdle. The end was drawn up and thrown over the left shoulder, leaving the right arm free, as it had no sleeves. The ordinary colour of the toga was white; but this was changed for a dark colour in mourning. The chief dignitaries of the state were distinguished by a purple band affixed to the edge of the toga, which was then called *prætexta*. An embroidered toga was worn by generals when they triumphed. (Rich, *Dictionary of Roman and Greek Antiquities*.)

Among women, the toga was only worn by the disreputable; the dress of the matron was the STOLA.

Toggel. A double cone of wood, firmly fixed in a loop at the end of a rope. By passing the toggel through another small loop in another rope, a strong junction is easily formed, which can be cancelled in a moment. Toggels are very useful in bending flags for signals.

Toise (Fr.). A French measure of length, containing six French feet, or 1·949040 mètres. The French toise is equivalent to 6·3945925 English feet. In Old English the equivalent of toise, i.e. *tey* or *teys*, is the same as the fathom.

Tokay. A wine made at Tokay in Hungary; it is luscious, and yet has an agreeable quickness of flavour. It is usually more or less turbid.

Token (Ger. zeichen; the root is found in the Gr. δείκνυμι, and the Lat. indicare, *to show*). Up to the Restoration, the government issued no copper money for purposes of

small change. There had been indeed no great necessity for such a currency in early times. The greater part of agricultural wages was paid in kind, there were no shops, and very little foreign produce was distributed by means of retail trade. Such articles of this character as were procurable, were obtained at those great fairs which played so important a part in mediæval and even in later economy, but which are now almost extinct. Besides, the denomination of the silver currency, before the reforms of Elizabeth, was low, pence being coined which were divisible by means of a cross on the reverse into four parts or farthings. As, however, intercourse with the Eastern world was made more familiar after the discovery of the Cape passage, and the English merchants contended with the Portuguese, Spaniards, and Dutch for a share in this lucrative trade, the supply of foreign commodities became more copious, and their use more diffused. Retail traders became more numerous, and supplied articles in smaller parcels, and the want of a small change currency was felt. To meet this want, and possibly to obtain some profit on the transaction, private individuals issued, there being no law to the contrary, copper pieces, called *tokens*, which the person whose name they bore pledged himself to redeem in silver, on demand. There was scarcely a village of any magnitude in which such a local currency did not circulate, and a complete collection of such tokens, if indeed it could be made, would contain many thousand specimens. The custom continued even up to the restoration of the currency in 1819, the Bank of England having for a short time even issued a currency of silver tokens.

This copper circulation was of a nature similar to those issues of notes in very small denominations which have characterised many foreign currencies. The value of the metal contained in the token was of course far below its nominal rate, and the circulation, if it could be effected in any quantity, was a source of considerable profit to the issuing parties, since during the time that the tokens were accepted and circulated, the proprietors of the local currency got the interest on the difference between the value of the tokens and the silver which they represented. Nor, except on the ground that it is an advantage to the state to retain the issue of the copper currency in its own hands, is there any reason why such a currency of tokens might not be permitted, as well as an issue of local notes. It is, however, a considerable advantage to the government to retain the monopoly of coining silver and copper, and it has therefore forbidden the issue of these tokens. It is well known that the silver and copper coins of this country are considerably overrated, and that therefore they are, to all intents, a currency of government tokens.

TOKEN. In Printing, ten quires eighteen sheets of *perfect* paper, or 258 sheets. It is reckoned an hour's work for a hand press, of ordinary work. In Moxon's time the token was ten quires.

Toleration (Lat. toleratio, from tolero, *I endure*). This word is used in a general sense to express impunity and safety in the state for all dissenters from the established church, who do not maintain any doctrines inconsistent with the peace and welfare of the state. Hence toleration implies a right of enjoying the benefit of the laws and of all social privileges, without any regard to difference of religion. The first toleration Act in England was passed in 1689; but it was not till 1829, when the Catholic Emancipation Bill was passed, that dissenters could be said to be on an equality with churchmen in every respect. For the connection between the idea of toleration and the secularisation of politics, see Lecky's *History of Rationalism in Europe*, ch. v.

Toll (A.-Sax.; Ger. zoll). The name usually given to the duties imposed on travellers and goods passing along public roads, bridges, &c. It is also used to indicate the payment to the corporation of a town, or to the lord or owner of a market or fair, upon sale of things tollable. Toll is sometimes taken by a man for every beast driven across his ground, and is then called *toll-traverse*; also by a town for beasts going through it, or over a bridge or ferry maintained at its cost, and is then called *toll-thorough*. The right to take an ancient toll rests upon prescription or a grant from the crown; tolls of modern introduction are established by Acts of Parliament, of which the Turnpike Acts are familiar instances. [TAILLE.]

Tolmen or **Dolmen.** In Antiquities. Borlase, in his *History of Cornwall*, gives this name to large stones with passages apparently hollowed through them, which are commonly believed to be Druidical remains. Other antiquaries describe under this name stone tables or altars resting on stone supports. There are so-called Tolmens in the Channel Islands, Brittany, Poitou, and in the central parts of France. See also *Archæologia*, vol. ii. and vol. viii. p. 210, where there is a description and representation of a celebrated one at Primham Rocks, in Yorkshire.

Tolsey. An ancient name for a place where tolls were assessed or collected, and at which, consequently, other mercantile business was often carried on. Thus a local court at Bristol was known as the Tolsey court. The word *Tolbooth* has, no doubt, a similar origin.

Tolu Balsam. The concrete balsam of *Myrospermum toluiferum*, a tree growing in the warmest parts of South America. This substance is pale brown; brittle in cold, but tenacious in hot weather; fragrant when heated, and entirely soluble in alcohol. It contains *cinnamic acid*.

Toluidine. An organic base obtained by the action of sulphide of ammonium upon nitro-toluol. It is a white crystalline substance, fusing at 104° Fahr. (40° C.), and boiling at 386·4 Fahr. (198° C.). Its formula is $C_{14}H_9N$.

Toluol. An oily hydrocarbon obtained by distillation from Tolu Balsam; it also exists in coal tar. Its composition is $C_{14}\ H_8$. It boils at 237·2 Fahr. (114° C.).

Tomato (Malay tamatta). The Love-apple, *Lycopersicum esculentum*, a Solanaceous plant, whose fruits are much esteemed in cookery. The *Solanum anthropophagorum*, which the Feejeans eat at their feasts of human flesh, is hence called the *Cannibal's Tomato*.

Tomb (Gr. τύμβος, Lat. tumulus). This word, which signifies strictly a place where a dead body is burnt, is commonly used to denote both the grave or sepulchre in which the body of a deceased person is interred, and a monument erected in his memory. In many countries it was customary to burn the bodies of the dead, and to collect the ashes into an Urn, which was deposited in a tomb. The tombs of the Jews were generally hollow places hewn out of a rock. The Greeks constructed their tombs outside the walls of their cities, with the exception of those raised to distinguished personages. The same distinction was observed by the Romans; their sepulchres were in the country near the high roads, and none but emperors, vestals, and great personages had the privilege of burial within the walls. In Etruria, many ancient tombs have been discovered containing beautiful vases, for full particulars respecting which the reader may consult Dennis's *Cities and Cemeteries of Etruria*. See, for the tombs of the Egyptians, Sir G. Wilkinson's *Manners of the Ancient Egyptians*, vol. iii. p. 183.

Tombac. An alloy of copper and zinc, or a species of brass with excess of zinc. When arsenic is added, it forms *white tombac*.

Tombazite. A variety of Gersdorffite, containing nickel, arsenic, and a little sulphur, with traces of cobalt and iron. It is found in cubical crystals of a bronze-yellow or pinchbeck-brown colour, near Lobenstein in Thuringia.

Tomentose (Lat. tomentum). In Botany, this term is applied to surfaces covered with dense scarcely rigid short hairs, so as to be sensibly woolly to the touch.

Tomentum (Lat.). In Botany, the down which produces the tomentose character on the surface of plants.

Tomoisite. An amorphous compact silicate of manganese from the Harz.

Tompion (Fr. tampon). In Artillery, a conical plug or stopper, placed in the muzzle of a gun to keep out the wet.

Ton (A.-Sax. tunna). A denomination of weight equal to 20 cwt. or 2,240 lbs. avoirdupois. The *long ton*, often used in wholesale dealings, is equal to 21 cwt. or 2,352 lbs. avoirdupois. *Ton* is also the name of an English measure of capacity containing 252 gallons; but when used in the latter sense, the word is usually written *tun*.

Ton. On Shipboard, forty cubic feet.

Tonality. In Music, this rather vague word is used generally to denote that peculiarity which modern music possesses, in consequence of its being written in definite keys, thereby conforming to certain defined arrangements of tones and semitones in the diatonic scale.

Tondino (Ital.). In Architecture, the same as Astragal.

Tone (Gr. τόνος, from τείνω, *to stretch*). In Music, this word has several meanings.

1. It refers to the quality of sound emitted by any musical instrument; thus, we say a pianoforte or a violin has a *good* tone, a *powerful* tone, a *soft* tone, a *sweet* tone, &c.

2. We speak, in common language, of musical tones as synonymous with musical sounds.

3. A tone is the musical interval comprised between two sounds, whose vibrations are in the ratio of 8 : 9.

Tone. In Physiology, a degree of firmness and tension in certain soft tissues, as contradistinguished from *flabbiness*: it is commonly applied to the muscles, in which the *tone* depends on a state of passive contraction, dependent on the connection of their nerves with the myelon, and which is lost when that connection, or the myelon itself, is destroyed.

Tones, Ecclesiastical. In Music, the eight modes, now generally called the Gregorian Chants, in which the psalms of the Catholic Church are intoned. Pope Gregory the Great has been considered the inventor of them.

Tongue (A.-Sax. tunga; Goth. tuggo; Ger. zunge; Celtic dingua, standing to the Lat. lingua, in the relation of Lat. lacryma, Fr. larme; to Gr. δάκρυμα, Goth. tagr, Eng. *tear*). In Anatomy, the organ of taste; a soft fleshy viscus, movable in all directions, composed of muscular fibres covered by a membrane, upon which, especially at the tip and sides, are numerous nervous papillæ. The tongue is largely supplied by blood-vessels, its arteries being branches of the ranine and labial, and its veins emptying into the great linguals which proceed to the external jugular; the nerves come from the fifth, eighth, and ninth pairs. The tongue performs important functions, not only in tasting, but in articulating, and in eating, chewing, or swallowing food, and in receiving drink.

Tongue. In Architecture. [Groove.]

Tonic (from *tone*). In Music, the principal or key-note of the scale. It is the chief sound upon which all regular melodies depend, and in which they, or at least the bass accompanying them, should usually terminate.

Tonics. Medicines which gradually and permanently increase the tonicity of the system, strengthening and invigorating it when in a debilitated condition; they increase the appetite, assist digestion, and thus, by increasing nutrition, give firmness to the muscular and circulating system. The principal tonics are to be found among the vegetable astringents and bitters, the mineral acids, and the preparations of iron.

Tonka or Tonquin Bean. The fruit of the *Dipteryx odorata*. It is used as a perfume, especially for snuff; its odour, resembling that of new hay, is derived from a concrete volatile oil which chemists have termed COUMARIN, or *Tonka-Camphor*. [DIPTERYX.] A similar substance may also be extracted from the flowers of Melilot (*Melilotus officinalis*). [MELILOTUS.]

Tonnage. This word implied originally the number of tons weight which a vessel might safely carry. It is now the gauge of a ship's dimensions, and the standard for tolls, dues, &c. It is so important a subject in its bearing on all matters of mercantile marine, that some detail of the mode of admeasurement appears requisite. Prior to January 1836, the rule established by Act of Parliament for the measurement of the tonnage of ships was founded on erroneous principles, and led to the most mischievous consequences.

By considering the breadth and depth as nearly the same, the rule implied the square of the breadth; and hence increasing the breadth of a vessel increased her *nominal* tonnage for the payment of dues more than it increased her real capacity. Under this pernicious system, vessels came to be built narrow and deep; and were thus not only less efficient, but highly dangerous. In 1823 a committee, of which Dr. T. Young was chairman, proposed to measure the internal capacity by taking the breadth and depth at each quarter of the length; but for some reason no step was taken. In 1832 another committee was appointed to consider the subject; and they concluded their labours in 1834 by recommending the method of Mr. Riddle, of the Royal Hospital, Greenwich. Mr. Riddle inferred that since a great number of direct measures for capacity would afford a result very near the truth, an approximation might be obtained by means of a smaller number of measures, provided additional weight was given in the calculation to those dimensions which extend through a greater part of the hull. He obtained the multipliers of these dimensions—the midship breadth and depth—by trial, from the vessels measured for the guidance of the committee; and the method is therefore founded on an arithmetical fact. Having been adopted by all vessels registered under the Board of Trade as the basis for dock dues, &c., this system of measuring tonnage was enacted by Parliament in 1835 (to the great improvement of shipbuilding), and, with much modification, made yet more compulsory by the Merchant Shipping Act of 1854. The rule, briefly expressed, as laid down in the Act of 1854 (17 & 18 Vict. c. 104 ss. 20–29), is as follows:—

All dimensions to be taken in feet and decimal parts of feet.

1. Measure the length on the *tonnage deck* from the inside of the inner plank at the side of the stem to the inside of the midship stern timber.

The *tonnage deck* is the upper deck of ships with less than three decks; the second deck from below if there be three or more decks.

2. Divide the length of the tonnage deck into equal parts as follows:—

If not exceeding	50 feet long,	into	4	parts.
,, ,,	120	,, ,,	6	,,
,, ,,	180	,, ,,	8	,,
,, ,,	225	,, ,,	10	,,
Above	225	,, ,,	12	,,

3. At each point obtained by rule 2, compute the transverse area of the ship, by taking the depth below the tonnage deck from a point one-third of the round of the beam below such deck to the upper side of the floor timber at the inside of the limber-strake. Next ascertain the width at three points, found by dividing the depth into four parts if such depth amidships do not exceed sixteen feet, or at five points, the divisions between six parts, if it do; as well as at the top and bottom of such line of depth. Number these breadths 1, 2, &c. from above. (*a.*) In the case of the line divided into four, multiply the second and fourth breadths by four; and the third by two: add these products to the sum of the first and fifth breadths; multiply the total by one-third of the common interval between the breadths: the product shall be deemed the transverse area. (*b.*) In the case of the line of depth divided into six, multiply the second, fourth, and sixth depths by four; and the third and fifth by two; to the sum of these products add the first and seventh breadths; multiply the total sum by one-third the common interval between the breadths: the result shall be deemed the transverse area.

4. Having found these transverse areas, number them 1, 2, &c. from the bow; No. 1 being at the extreme bow end of the line of length and the last number at the extreme stern end of such line. Then multiply every even-numbered area by four, and each odd-numbered (except No. 1 and the last) by two. To the sum of these products add the first and last areas if they yield anything. Multiply the total by one-third the common distance between the areas, and divide the product by 100. The quotient shall be the tonnage under the tonnage deck and the register tonnage, subject to certain additions and deductions, of the ship.

In vessels with a poop or a break in the upper deck, measure the mean horizontal area and height of such poop; multiply these together, and divide by 100, and add the result to the former tonnage.

If a vessel have more than three decks, the tonnage due to each between-deck space above the tonnage deck shall be found, as in the case of the poop, and added. In open vessels, the depth is measured from the upper edge of the upper strake.

In vessels propelled otherwise than by sails, the tonnage due to the content of the engine room, found by multiplying together the length, breadth, and height, and by dividing the product by 100, is to be deducted from the gross

tonnage. The space occupied by a screw shaft is to be included as part of the engine-room.

The relative capacities of ships are determined very nearly by this method, i.e. within little more than four or five per cent. generally; though, in extreme cases, the difference may amount to ten or twelve per cent. Even this, however, is insignificant, as compared with the usual errors of the former method. The divisor by which cubic content is reduced to nominal tonnage has been adopted merely in order that, while the reputed tonnage of most kinds of vessels would be corrected by the new rule, the total registered tonnage of the kingdom might remain unaltered. By the new method the dues paid on tonnage are proportioned to the capacities of the vessels; and as no advantage is gained in these respects by defective forms, a marked improvement in merchant vessels has followed the passing of the Act.

The new measurement is universally adopted for vessels registered under the Board of Trade; each ship being required (to be deemed a British merchant ship) to have her number and tonnage carved or painted conspicuously on her main beam; but pleasure yachts still, for the most part, cling to the O.M. or old measurement.

Tonnage and Poundage. *Tonnage* was a duty upon all wines imported over and above *prisage*. [PRISAGE.] *Poundage* was a duty imposed ad valorem at the rate of twelve pence in the pound on all other merchandise whatever. These duties were granted to the crown by parliament, at first periodically, then annually, till the reign of Charles I., who collected them for fifteen years without the consent of parliament; a right formally renounced by stat. 16 Ch. I. c. 8. After the Restoration, these duties were continued by parliament from time to time till the year 1787, when they were merged in the general customs duties by the first Customs Consolidation Act (27 Geo. III. c. 13).

Tonsillitis. Inflammation of the tonsils. [QUINSEY.]

Tonsils (Lat. tonsilla, dim. of tonsa, part. of tondeo, *to shear* or *cut off*). An oblong suboval gland on each side of the fauces, and opening into the cavity of the mouth by several large ducts.

Tonsure (Lat. tonsura, from tondeo, *I shave*). The *crown* or space on the top of the head kept shaven by persons in orders, or belonging to religious bodies in the Roman and other churches. Tonsure is said to be of two kinds; one denominated after St. Paul, across the whole front of the head from ear to ear, in use in the Eastern churches, (and those of Britain and Ireland); the other from St. Peter, the ordinary Romish. Tonsure was first rendered obligatory by the Fourth Council of Toledo, A.D. 633. The tonsure is larger in proportion to the rank of the person in the church. It is supposed to represent the crown of thorns placed on the head of Christ when before Pilate.

Tontine. At or about the conclusion of the seventeenth century, one Tonti, a Neapolitan, suggested to the French government a new method of raising money, on the joint lives of a number of subscribers to a government fund. The suggestion was neglected in France, but adopted in England, and for some time joint annuities, under the name of *tontines*, from the inventor, were a customary means of borrowing money.

A tontine is an ingenious scheme in which the prudential practice of securing a fixed provision on the basis of a government obligation is coupled with the speculative tendency of considering one's own chance of life better than that of one's neighbour. A number of persons join in equal or varying shares towards a government loan, and receive a proportionate annuity, with a right of survivorship, the last survivor receiving the whole sum annually paid, or, as is generally the case, such a proportion of the whole sum as has been determined at the time in which the tontine was created. Thus, if a thousand persons subscribed a fund sufficient, on calculations made by government as to the expectation of loss, to secure annuities of 100*l*. to each subscriber, the last survivor would on the first hypothesis receive 100,000*l*. a year, or whatever sum, say 10,000*l*. or 20,000*l*., was agreed on when the tontine was created, as the annuity of the last survivor.

Tontines have long ceased to be favourite schemes of government. On the whole, the state lost considerably by the arrangement. This was due to two causes at least. The calculations made as to the probable duration of human life, having been taken on the whole from insurance tables, erred on the side of deficiency, and thus, on the whole, the ordinary annuitant, who would seldom purchase unless with a good prospect of life, gained considerably. Again, tontines were frequent subjects for investment on the part of speculators and even of companies. To make them as profitable as possible, agents were despatched over the whole country, to search out families noted for longevity, and select from them individuals of the healthiest frame and most temperate habits. As a consequence, the investment in tontine funds was advantageous to the purchaser and a loss to government. It may be observed that the dead weight annuity of the Bank of England, which expires in 1867, is in principle a tontine on a gigantic scale, the annuities payable in 1823 having amounted to upwards of 5,000,000*l*., and the Bank having stipulated to satisfy them in consideration of an annual payment of 585,740*l*. for forty-four years commencing on April 5, 1823.

Toon Wood. The wood of *Cedrela Toona.*

Toot Plant. A poisonous New Zealand shrub, *Coriaria ruscifolia.*

Toothache-tree. One of the names of the *Xanthoxylon fraxineum.*

Toothing. In Architecture, bricks alternately projecting at the end of a wall, in order that they may be bonded into a continuation of it when the remainder is carried up.

Top (A.-Sax.). In Naval language, a small light platform around the lower mast-head.

Top, Spinning. A well-known toy. The steady motion which a well-spun top soon acquires suggested to Mr. Sisson, about eighty years ago, the employment of a mirror placed upon it at right angles to its axis, as an artificial horizon which might probably be used at sea; and on sending out the first of the late polar expeditions, the attention of Mr. Troughton was turned to the subject. But though useful observations might have been made on land with the instrument which he constructed, it was not found at sea to give results of any practical value. More recently Mr. Piazzi Smyth has constructed on this principle a contrivance which he calls a *free revolving stand*, and which has been used with some success.

Top-and-Butt. An arrangement of the planks of the outside by which economy of wood is secured. They are so bolted on that two rows produce a straight band.

Top-mast. The second mast from the deck, being above the lower mast, and below the topgallant mast. It is sustained by a fid, through its base, which rests on the trestle-trees, steadiness being maintained by the cap on the lower mast-head, the topmast shrouds, stays, and backstays.

Toparchy (Gr. τοπαρχία, from τόπος, *a place*, and ἄρχω, *I rule*). In Ancient History, a small state or lordship consisting only of a few cities or towns; or a petty country under the sway of a toparch. Thus Judæa was anciently divided into ten toparchies.

Topaz. A silicate of alumina containing fluorine. It occurs crystallised and in water-worn pebbles, and is harder than Quartz, but less hard than Ruby. It is limpid and transparent, colourless or yellow, or of a wine-colour, blue, green, &c.

When heated, the Brazilian Topaz becomes rose-red, and is sometimes in this state passed off as a Ruby; the Saxon Topaz loses its colour by heat. When without flaws and of a good colour, it is much employed in jewellery. The Saxon is usually paler than the Brazilian, which often has a pinkish hue; the Siberian Topaz is usually colourless, and the Scotch has a blue tinge. The name is derived from Topazos, an island in the Red Sea, whence the ancients procured their Topazes. (Bristow's *Glossary of Mineralogy*, p. 383.)

Topazine Quartz. [False Topaz; Smoky Quartz.]

Topazolite. A variety of lime-Garnet, found in translucent, honey-yellow crystals (which are sometimes of an olive-green colour), at Mussa in Piedmont.

Topchains. On Shipboard, chains used in action, by which the lower yard is hung in case of the slings being shot away.

Topgallant. That which is next above the topmast.

Tophet. Tophet, it would seem, was originally a garden or pleasance of the Jewish kings, which some among them defiled by the worship of Baal and by human sacrifices offered to Moloch. Afterwards the name was used to denote any polluted or unclean place.

The name is derived by some from Heb. toph, *a drum*, on account of the beating of drums and other instruments by which the cries of the children sacrificed to Moloch were stifled, or which were used there on festive occasions.

Tophus (Lat.). A soft tumour upon a bone, also a term used to designate gouty deposit in the smaller joints.

Tophus. A name given to porous deposits of calcareous matter from water. Probably the term *tufa* or *tuff*, which is ordinarily used to denote such deposits, is a corruption of the word *tophus*.

Topiary Work (Lat. ars topiaria). In Horticulture, this expression is used to designate the fanciful shapes formerly given, by cutting and trimming, to arbours, hedges, and trees in formal gardens. Topiary work is now happily obsolete, and ornamental trees are suffered to grow without being tortured into the unseemly forms which once were given to them. The term does not include such moderate knife-pruning as may be designed to give finish to a naturally graceful shape, but is applied to such cutting (clipping) as gives an artificial form or outline.

Topics (Gr. τοπικός, from τόπος, *a place*). In Rhetoric. By abstracting from a proposition which conveys a truth in the concrete (i.e. respecting certain circumstances expressed in the terms of the proposition) a portion of those circumstances denominated accidental, we arrive at the same truth in the abstract, or (in stricter language) in a more widely applicable form, accommodated to many different sets of accidental circumstances. Thus, for example, in jurisprudence, from an investigation of the truth in various insulated cases in which a too strict application of legal principles has been attended with evil effects, we deduce the general truth that such application is so attended; or, in the proverbial phrase, 'summum jus summa injuria.' Among the helps employed by the ancients in their favourite study of rhetoric was the collection and arrangement of a great variety of such general truths, according to the several sciences or subjects to which they belonged. These they termed *topoi*, or places; from which the modern term *topic* is derived. They considered it useful for the student in rhetoric to have at hand, by means of his memory, these compendious expressions of universal sentiment, and the general reasonings or declamations applicable to each of them, in order to employ them for particular use by performing the converse of that operation by which they were arrived at; viz. clothing them with the particular circumstances of the case. Thus the topos just cited might be useful to the forensic orator; it affords a subject for reasoning and

declamation applicable to a great number of individual instances. Many of these topics answer to what in modern phrase we should term *axioms*; and, indeed, some of the axioms of pure mathematics are enumerated by Aristotle among the topics which are proper to every species of oratory.

Topography (Gr. τοπογραφία). Strictly the description of a place, or the science of describing places (distinguished from *chorography*, or the description of a district, and from *geography*, the description of the earth).

Topping Lift. On Shipboard, tackle for raising the outer end of a gaff or boom.

Toptimbers. In the ribs of a ship's side, those pieces which are next above the futtocks.

Torbane Hill Coal or **Torbanite.** A kind of Cannel Coal found at Torbane and other places near Bathgate in Linlithgowshire, in the upper coal-measures of Scotland, where it sometimes passes into Blackband Ironstone and into ordinary Cannel. This mineral is the most valuable coal hitherto discovered for making gas and paraffine. (Ure's *Dict. of Arts, &c.*)

Torberite. A Mineralogical synonym for Copper-Uranite.

Toreumatology (Gr. τόρευμα, *embossed work*, and λόγος). This word signifies either the science or art of sculpture, or a description of ancient and modern sculpture and bas-relief.

Toreutic (Gr. τορευτικός, *belonging to work in relief*). In Sculpture, a term applied to such objects as are executed with high finish, delicacy, and polish; but properly to all figures in hard wood, ivory, &c. and often restricted to metallic carvings or castings in basso-rilievo. But in its widest sense it signifies sculpture in any style, or in any material, whether modelled, carved, or cast.

Toria. An Eastern name for *Sinapis glauca*, a species extensively cultivated in India for the oil obtained from the seed.

Tormentil Root. The root of the *Potentilla Tormentilla*. It is occasionally used in medicine as an astringent.

Tornado (Span.). A violent hurricane or gust of wind, which, arising suddenly from the shore, veers round to all points of the compass, and indeed has been described as blowing from all points at once. Tornadoes are usually accompanied with thunder storms, and are generally of short duration. They are frequent in the Chinese seas and the West Indies. [Storm.]

Tornatella. A genus of oval marine Univalves belonging to the *Plicaceæ*, found fossil in the oolite and superjacent strata. Recent tornatellæ are found in shallow water, creeping upon and furrowing the sand.

Torpedo (Lat.). A genus of Cartilaginous fishes, separated from the *Raiæ* of Linnæus on account of the circular form of the body, and more especially from the presence of the electrical organs on which that form of the body mainly depends. Violent shocks are experienced on touching the living and active torpedo. It is probable that it exerts its electrifying or benumbing powers in order to secure its prey; and it is certain that the same power is employed in defending itself against assailants, to whose assaults it would be otherwise more exposed than are the ordinary rays; for the torpedo has a smooth skin, and is not defended by the spiny tubercles, or barbed and pointed bony weapons, with which the non-electric rays are provided.

Torpedo. In Nautical language, the name applied to certain vessels constructed for navigating under water, the power of sustaining life and of moving the structure being derived from compressed air. Various designs of this class have at different times been brought to the test of experiments, but no practical results have hitherto followed.

The word has in recent years been also used to designate certain submerged bombshells, which are placed in the way of ships, to be fired beneath them. They were used during both the Russian and American wars. The torpedoes are of two kinds, one self-acting, which is equally dangerous to friend and foe, and presents the especial difficulty that it is no easy matter to fish it up without an explosion; the other class are fired by electricity. The self-acting, of which there are many varieties, may in general terms be described as consisting of an inverted cone of thin iron, containing gunpowder, in communication with which is a small case of lime. In this lime is a glass tube of sulphuric acid, which is connected with an iron rod projecting from the top of the torpedo: on a ship striking this rod, or any branch rod attached to it, it breaks the glass tube: the acid fires the lime, and the heat explodes the powder.

The electric torpedoes are of two sorts; one in which two observers, at separate points in the wire circuit connecting the torpedo with the electric battery, look along lines intersecting at the machine. Each maintains the electric connection at his station so long as an enemy's ship is over his line of view, and when both observers simultaneously connect, the electric circuit becomes complete, and the powder is blown up, the ship being of necessity where the lines of sight cross. The remaining sort of electric torpedo is self-firing. A covered wire is laid from a battery on shore to the outside of a metal cylinder in the middle of the torpedo. The other pole of the battery is connected by a wire with the water. An iron rod rises from the centre of the torpedo, with attached feelers. Its lower end has a certain play within the metallic cylinder. When an enemy's ship approaches, the shore communication is made complete by attendants on the land: if the ship strike the feel-rod, the lower end is brought against the side of the cylinder, and from the strong conductivity of the water the entire circuit is immediately formed, when the apparatus explodes. The electric torpedoes are best adapted for rivers or parts near the shore.

Three kinds of self-acting torpedoes were

employed by the Confederates at Fort Wagner, which are fully described in General Gillmore's *Artillery and Engineer Operations against Charleston.* Being injudiciously placed, they were as great an impediment to the Confederates as to the attacking Federals, entirely hindering them from issuing out to attack the besiegers, who could thus continue their works in perfect security from sorties.

Torpidity. [HYBERNATION.]

Torques. In Antiquities, the Latin name for a chain or collar formed of a number of small ringlets interlaced with each other, framed of metal, and worn round the neck. No ornament perhaps was of more early or general use. It was in use among the Greeks and Romans, but peculiarly among the Celtic nations. The legends respecting the torques of the Gauls who invaded Rome are well known. T. Manlius Torquatus is said to have derived his surname from having vanquished a Gaulish warrior, whom he deprived of his chain. (Livy, lib. vii. ch. x.) No relic is more commonly found in this country by antiquarian explorers. Boadicea wore a large golden torques. (Dio. Cass. lxii.) See the *Archæologia*, vol. xiv. p. 97 and passim, for descriptions of particular specimens.

Torrefaction (Lat. torrefacio, *I roast*). The operation of roasting ores to deprive them of sulphur, arsenic, or other volatile ingredients. When drugs are highly dried, or partially toasted or roasted, they are also said to be torrefied.

Torrelite. A name for Columbite, after Dr. J. Torrey.

Torreya (after Dr. Torrey, an American botanist). A genus of *Taxaceæ*, to which the name of Stinking Yews has been given, from the disagreeable smell given off by the leaves and wood when bruised or burnt. They are small evergreen trees of North America, China, or Japan, and grow from twenty to fifty feet high with two-ranked linear or lanceolate leaves and diœcious flowers. The fruits are drupaceous. The timber of *T. taxifolia* and *T. myristica* is heavy and close-grained, but has a disagreeable smell. The kernels of the seeds of *T. nucifera* yield an oil which is used for culinary purposes, but the kernel itself is too astringent to be eaten.

Torricellian Vacuum. In Physics, the vacuum produced by inverting a tube of sufficient length, filled with mercury or any other fluid, in a vessel containing a portion of the same fluid, and allowing the fluid in the tube to descend until its weight is counterbalanced by that of the atmosphere. In this manner the first barometers were formed by Torricelli, and thence called *Torricellian tubes.* [BAROMETER.]

Torrid Zone. In Geography, the zone of the earth included between the tropics of Cancer and Capricorn. It extends from the equator, on both sides, to the parallel corresponding to the sun's greatest declination, about 23½ degrees. [ECLIPTIC ZONE.]

Torsion (Lat. tortio, from torqueo, *I twist*). In Geometry, the departure of a curve from the plane containing three consecutive elements. The angle $d\sigma$ between two consecutive osculating planes, is termed the *angle of torsion*, and the *torsion* itself, or second curvature, as the French term it, is measured by the quantity $\frac{d\sigma}{ds}$, where ds is the element of the arc of the curve. The inverse of this quantity, viz. $\frac{ds}{d\sigma}=r$, is called the *radius of torsion.* The angle of torsion of a curve is always equal to the angle of contact of the cuspidal edge of the polar developable, and the angle of torsion of the latter is equal to the angle of contact of the original curve. The radii of torsion and curvature, however, have not the same reciprocal relations, since the arcs of the two curves are in general unequal. [POLAR DEVELOPABLE.]

Some continental writers have also considered the departure of a curve from the osculating sphere determined by four consecutive points, to which they have given the name *spherical torsion.* (Grunert's *Archiv der Math.* th. 19.)

TORSION. In Mechanics, the twisting or wrenching of a body by the exertion of a lateral force. If a slender rod of metal suspended vertically, and having its upper end fixed, be twisted through a certain angle by a force acting in a plane perpendicular to its axis, it will, on the removal of the force, untwist itself, or return in the opposite direction with a greater or less velocity, and, after a series of oscillations, will come to rest in its original position. The limits of torsion within which the body will return to its original state depend upon its elasticity. A fine wire of a few feet in length may be twisted through several revolutions without impairing its elasticity; and within those limits the force evolved is found to be perfectly regular, and directly proportional to the angular displacement from the position of rest. If the angular displacement exceed a certain limit, the particles of the body will be wrenched asunder; or if the elasticity be not perfect (as in a wire of lead, for example) before disruption takes place, the particles will assume a new arrangement or *take a set,* and will not return to their original position on the withdrawal of the disturbing force.

The resistance which cylinders or prisms formed of different substances oppose to torsion, furnishes one of the usual methods of determining the elasticity and strength of materials; and the property which a metallic wire or thread stretched by a small weight possesses of becoming twisted and untwisted in a series of isochronous and perfectly regular oscillations, has been ingeniously applied in the torsion balance to the measurement of very minute forces, and thereby to the establishment of the fundamental laws of electricity and magnetism, and to the determination of the mean density of the earth. [BALANCE OF TORSION.]

The laws of torsion have been experimentally investigated by Coulomb in a variety of substances. The method which he employed consisted in attaching a body of given form and dimensions to the extremity of the wire, and, after twisting it through a certain angle, abandoning it to the action of the force evolved, and observing the time of the oscillations. The following general laws were found to hold good:—

1. On loading a wire or thread with different weights, it will settle in different positions of stable equilibrium; i.e. an index attached to the weight will point in different directions if the weight be varied, and the angular deviation may amount even to a whole circumference.

2. The oscillations are isochronous.

3. The time of oscillation is proportional to the square root of the weight which stretches the wire.

4. The time of oscillation is as the square root of the length of the wire.

5. The time of oscillation is inversely as the square of the diameter of the wire.

From the second of these laws it follows that when the wire is twisted round from the position of rest, the force with which it tends to return to that position is proportional to the angle to be described in order to attain it. For it is a general result of mechanics, that all motions produced by forces acting according to this law have the property of isochronism: i.e. the oscillations are performed in equal times, whatever be the length of the arc. This fundamental property is usually enunciated by saying that the force of torsion is proportional to the angle of torsion.

Let F denote the force of torsion, measured by the weight which it would be necessary to apply by means of a pulley to a point p, situated at the unit of distance (one inch) from the axis of the wire, and invariably connected with it, to cause the point p to describe an arc of a circle equal in length to the unit of distance; then, by the property enunciated, the force which must be applied at p in order that the point may describe any arc ϕ is expressed by $F \times \phi$.

On this principle of the proportionality of the impelling force to the angle of deviation, the problem of determining the time of an oscillation is solved. Suppose a body of any form attached to the extremity of a slender wire the weight of which, when compared with that of the body, may be neglected, and let dm be an element of mass, r the distance of dm from the axis of the wire, and T the time of an oscillation; the solution of the problem gives—

$$T = \pi \sqrt{\left(\frac{\int r^2 dm}{F}\right)} \text{ or } T^2 = \pi^2 \frac{\int r^2 dm}{F}$$

where the integral $\int r^2\, dm$ is the *moment of inertia* of the attached body. If the body be a cylinder whose axis coincides with that of the wire, and if a denote its radius and M its mass, then $\int r^2\, dm = \frac{1}{2} M\, a^2$; or, expressing the mass in terms of the weight, and observing that if the weight be denoted by P, and the accelerating force of gravity by g ($=32{\cdot}1908$ feet or $386{\cdot}2894$ inches in a second), we have $P = Mg$, $\int r^2 dm = Pa^2 + 2g$. Hence the expression for the time becomes $T = \pi a \sqrt{\frac{P}{2gF}}$.

If the attached body were a slender cylindrical needle suspended horizontally by its middle to the wire, we should, on denoting its length by $2l$, have $\int r^2 dm = \frac{1}{3} M l^2$; whence

$$T = \pi l \sqrt{\frac{P}{3gF}}.$$

The following results are deduced from the formula: 1. The force of torsion is independent of the weight which stretches the wire, or F remains constant while P is varied. For suppose P to become P′, and let T′ be the corresponding time of oscillation, and F′ the corresponding force; we have then

$$T^2 = \frac{\pi^2 a^2 P}{2gF}, T'^2 = \frac{\pi^2 a^2 P'}{2gF'};$$

whence $T^2 : T'^2 = P F' : P' F$. But, by the third experimental law, $T^2 : T'^2 = P : P'$; therefore $F' = F$.

2. The force is inversely as the length of the wire. For, supposing P to remain constant, we have $T^2 : T'^2 = F' : F$. But, by the fourth experimental law, $T^2 : T'^2 = l : l'$; whence $F' : F = l : l'$.

3. The force is proportional to the fourth power of the diameter of the wire. Let there be two wires of the same substance, but of different diameters, D and D′, and stretched by the same weight P; and let T and T′ be the corresponding times. By the fifth experimental law, we have $T : T' = D'^2 : D^2$. But it has been shown that $T^2 : T'^2 = F' : F$; therefore $F : F' = D^4 : D'^4$.

For the demonstration of the fundamental formula, viz. $T^2 F = \pi^2 \int r^2 dm$, see Coulomb, *Théorie des Machines Simples*, or Biot, *Traité de Physique*, tom. i.

Torso (Ital.). In Sculpture, a statue of which nothing but the trunk of the human figure remains, as for instance the celebrated Torso of Apollonius, now in the Vatican.

Tort (Fr. *wrong*, from Lat. tortus, *twisted*). In Law, this word signifies injustice or injury. 'Actions founded on *torts*' are such actions as are brought for the redress of wrongs not arising from breaches of contract; they are sometimes described as actions *ex delicto*.

Tortoise. This name is usually applied to species of that division of the Linnæan genus *Testudo* including the terrestrial Chelonians, to which the generic name is now limited. [TESTUDO.]

Tortoise Plant. *Testudinaria elephantipes.*

Tortoise Shell. The name given to the horny scutes or plates of the sea turtles; and in particular to those of the hawk's-bill turtle, *Chelone imbricata.*

Tortrices (Lat. torqueo, *I wreathe*). The name of a tribe of nocturnal Lepidopterous insects, comprising those the larvæ of which live concealed in leaves, which they roll around them for the purpose.

Torture (Lat. torqueo, *I twist* or *torment*). In a Legal sense, the infliction of pain on an accused person in order to extort an avowal of guilt, or revelation of accomplices. Such a practice is sufficiently common among all half-civilised nations; but the Greeks and Romans were perhaps the first who introduced it as a part of their regular proceedings in criminal cases. Both at Athens and Rome torture was, however, considered as applicable only to extort evidence from slaves: towards them it was used profusely; and it was, in fact, a usual occurrence to order a whole family of slaves to the torture, in order to extract revelations where a crime had been committed, as, for instance, the murder of the master. Cicero, in several passages, condemns the use of torture; and Ulpian (Lex i. *De Quæstionibus*) says, 'Res est fragilis et periculosa, et quæ veritatem fallit, nam plerique patientiâ sive duritiâ tormentorem ita et tormenta contemnunt, ut exprimi eis veritas nullo modo possit; alii tantâ sunt impatientiâ ut quid vis mentiri quam pati tormenta malint.' (As to the torture at Rome, see Gibbon, vol. ii. p. 59, 4to ed.) Notwithstanding these recorded opinions of the highest luminaries of ancient jurisprudence, torture was adopted along with the rest of the process of the civil law in most European countries. [For its use in France, see QUESTION.] The general principle of the civilians was, that it could not be used unless *vehement suspicion* warranted its application. But no very definite meaning was attached in practice to these words; especially in Germany, where the abuse seems to have been carried to the greatest extent by the ignorant and cruel tribunals of her smaller states. When Howard visited the prisons of that country (about 1770), it was still in general use. (*Account of Prisons.*) The writings of various philosophical authors of the eighteenth century, especially Voltaire, Thomasius, and Beccaria (whose short treatise, *Dei Delitti e delle Pene,* obtained such singular notoriety), effected much towards bringing its employment into disrepute; but its general abolition can only be attributed to the superior regard for the rights of man introduced everywhere by the agitation of the French revolution. In England, judicial torture was not recognised by the common law (for the peine forte et dure hardly falls within the same definition); and that it was also nearly unknown in practice, in the fourteenth century at least, may be inferred from the reluctance of Edward II. to submit the Templars to torture, which was overcome by the instances of Pope Clement V., and from a curious paper of questions addressed on that occasion by the archbishop of York to some divines, from which it appears that *no torturer could at that time be found in England.* (Raynouard, *Mèmoires sur les Templiers*; Hallam's *Constitutional History.*) The rack is said to have been introduced as an engine of state by the duke of Exeter in the reign of Henry VI. However this may be, during the whole of the sixteenth century we find that the Privy Council assumed and exercised the right to direct torture-warrants to the lieutenant of the Tower and other officers, commanding them to submit to the torture persons accused not only of state offences, but of ordinary municipal crimes, when strong suspicion, but no sufficient evidence, existed. Torture warrants were also issued, not by the council, but under the sign manual only. During this period the council seems, in fact, to have acted as a supplementary tribunal in aid of the regular courts, for the purpose of extorting discoveries of criminal offences. The instances of torture of seminary priests, &c., in Elizabeth's reign, have been often cited; but it is not so generally known that the practice was not confined to accusations of treason and sedition, but extended to other cases. (Jardine's *Reading on the Use of Torture in England,* 1837.) Under James I. and Charles I. torture seems to have become less frequent, and to have been only employed in state offences; and this, perhaps, explains the well-known answer of the judges to Charles's question respecting Felton, the murderer of the duke of Buckingham, that he ought not to be tortured, 'for no such punishment is known to our law.' The last recorded case is that of William Archer, 1640; and as in that year the Act for the abolition of the Star Chamber granted a habeas corpus to all persons detained on warrants from the Privy Council, torture must then have been virtually abolished. In Scotland, it was so in the seventh year of Anne. For the frightful systems of torture employed by Italian tyrants, see Sismondi, *Histoire des Rèpubliques Italiennes,* iv. 282. A complete set of instruments of torture is, or was lately, shown at Ratisbon.

Torus (Lat.). In Architecture, a large moulding used in the bases of columns, the profile of which is semicircular.

TORUS. In Botany, the axis on which the various floral whorls within the calyx are seated. It is the same as Thalamus.

Tory. A well-known party name in English History. While the Presbyterian covenanters who rose against the government of Charles II. received the name of WHIGS, that of *Tory* was given to Popish outlaws who found a refuge in the bogs of Ireland, and who were afterwards called *Whiteboys.* Hence the name was applied to Englishmen who refused to concur in excluding a Roman Catholic prince from the throne. (Macaulay's *History of England,* vol i. ch. iii.)

Down to the time when Hume wrote his *Essay on the Parties of Great Britain*, the conduct of the two great parties in the state (the Whigs and Tories) had been so vague and undetermined, as to have led him to declare his utter inability to tell their nature, pretensions, and principles. Of late years, the word *Tory* has been gradually displaced by *Conservative*. This term was originally assumed in contradistinction to *Destructives*, a name by which the more violent reformers came to be designated by their enemies; and it is now understood as referring to the whole Tory party, but more especially to what may be called the more liberal portion of that party.

Tosorthrus. [SESOSTRIS.]

Totipalmates (Lat. totus, *entire*, and palma, *a palm*). The name of a tribe of *Palmipedes*, or swimming birds, including those in which the hinder toe is enveloped in the same web with the three anterior toes.

Toucan or **Tucan.** [RHAMPHASTOS.]

Touch (Fr. toucher, Ger. ticken, akin to Lat. tango, te-tig-i, Gr. θιγγάνω, ἐ-θιγ-ον). In Medicine. The belief in the possibility of curing various maladies by the touch has produced many superstitions. Plutarch attributes singular virtues to the touch of King Pyrrhus of Epirus. According to Suetonius, Hadrian and Vespasian had the power of curing certain diseases in the same manner. In what period the opinion respecting the virtue of the touch of the kings of France and England in curing epilepsy, scrofulas, &c. had its origin, it is difficult to ascertain. André Dulaurent, chief physician of Henry IV. of France, published a treatise on the subject. The ceremony of touching, by the kings of France, was practised at the four great feasts of the year; sometimes as many as 1,500 were touched at a time. By an odd etiquette, the Spaniards had the first rank, then other foreigners, and the French last of all. The formula used at each imposition of the royal hand was, 'Le roi te touche, et Dieu te guérit.' Polydore Vergil attributes this virtue to Edward IV., and all our kings down to the end of the Stuart dynasty touched for the king's evil. Much efficacy has been attributed in different diseases, particularly tumours, &c., to the touch of the hand of a dead body; especially, according to Pliny and various modern authorities, of one who had died violently. Boyle endeavours to explain away part of the miracle by attributing some virtue to the coldness of the application.

TOUCH. In Naval language, the sails are said to *touch* when the wind comes edgeways upon them, and they consequently shiver.

TOUCH. One of the five senses, resident in the nervous papillæ of the skin; it is also the sensibility diffused over the whole body. It is more exquisite in some parts than others.

TOUCH. [SYCEE.]

Touch Needles. Small bars, consisting of gold and silver alloyed with various definite proportions of copper, are thus termed by assayers, who, by comparing their colour and streak upon a piece of hard black stone, such as basalt, with that of alloys of the precious metals, judge of the relative quantity of gold or silver in the latter. Hence also the term TOUCHSTONE.

Touchstone. A name for *Lydian Stone* or *Basanite*. A velvet-black silicious stone or flinty jasper, used on account of its hardness and blackness for testing the relative quantity of gold or silver in alloys of the precious metals. [TOUCH NEEDLES.]

Touchwood. One of the names given to *Polyporus igniarius*. The soft white substance into which wood is converted by the action of *Fungi* is also called *Touchwood*; of this, the ash, especially under the influence of *Polyporus squamosus*, affords good examples. Occasionally, when highly impregnated with mycelium, it has been observed to be luminous. It derives its name from its property of burning for many hours like tinder when once ignited. This decaying condition of wood is sometimes confounded with the powdery snuff-coloured mass into which wood is sometimes converted without the agency of *Fungi*, by a process of chemical combustion distinguished by the name of EREMACAUSIS. When wood is damp, or placed in an atmosphere charged with moisture, the oxygen of the air combines with the hydrogen, and carbonic acid is given off from the residue: and as this action constantly recurs, the texture of the wood is destroyed, and the whole is reduced into a crumbling mass, which contains a proportionally larger amount of carbon than the original wood. It is this evolution of carbonic acid in a damp atmosphere, when in contact with wood, which makes such situations prejudicial to health. This kind of decay, which often takes place in trees when no fungus is present, and which spreads from within outwards like a putrefactive ferment, contaminates the sound tissues which surround it. There is reason, moreover, for believing that the brown condition so common to diseased vegetable cells has a similar origin.

Tourmaline. A name for the more perfect forms of Schorl. It is chiefly composed of silica, alumina, boracic acid, &c., and has been divided by Rammelsberg into five sub-groups, viz. 1. *Magnesia Tourmaline*; 2. *Iron-magnesia Tourmaline*; 3. *Iron* or *Black Tourmaline*; 4. *Iron manganese-lithia Tourmaline*; 5. *Lithia Tourmaline*. (Bristow's *Glossary of Mineralogy*, p. 385.)

The transparent coloured varieties are sometimes cut into ring-stones, &c. and when reduced to thin slices are much valued for making experiments on the polarisation of light and for analysing the optical properties of other minerals. The Red Tourmaline or *Rubellite* possesses considerable beauty. The finest kinds of Tourmaline are brought from Brazil, Ceylon, Ava, and Siberia. Black Tour-

maline or Schorl is very abundant in the stanniferous granite of Cornwall, in the neighbourhood of St. Austell; and in the granite of Dartmoor in Devonshire, especially near Bovey Tracey.

Tourn. In Law, the tourn was the turn or circuit anciently made twice every year by the sheriff, for the purpose of holding in each hundred the great court leet of the county. The jurisdiction exercised by the sheriff on his tourn extended by the common law to the cognisance of all offences not capital; but sheriffs are prohibited by Magna Charta from holding any pleas of the crown in which they had a pecuniary interest in procuring a conviction; while a better tribunal was at the same time supplied by the establishment of annual circuits. The tourn, though never disallowed by law, has, with the curtailment of its jurisdiction, and the abandonment of the leet as a registry of pledges, long fallen into disuse; and the right of the jury or suitors at the tourn to present nuisances, or convict of minor offences, has, with other functions of courts leet, been transferred to the quarter sessions.

Tournament (Mod. Lat. torneamentum) or **Tourney** (originally derived from Fr. tourner, Mod. Lat. tornare, *to turn*). A military sport of the middle ages, which without doubt arose from the exercises of military training. A *joust* or *just* is, properly speaking, the encounter of two knights in this species of exercise; the *tournament*, an assembly held for the purpose of exhibiting such jousts, or the encounter of several knights on a side. The earlier tournaments were performed with the ordinary weapons of warfare, the lance and the sword; and the combatants had only the strength of their armour to rely on for their defence. It was a recognised custom, according to Meyrick (*Hist. of Ancient Armour*), that whoever slew or disabled an adversary in the tournament was indemnified against all consequences. The account of the tournament held by the count of Chablais in Savoy in honour of Edward I. on his return from Palestine to England, as described by Walsingham, represents a sort of violent mêlée, in which knights, squires, and archers were engaged on both sides, endeavouring to unhorse the riders and overthrow the footmen by every possible means. But in the course of time this chivalric amusement became the subject of minute regulations, which in some degree diminished the danger of the sport. The English *Statuta Armorum de Torneamentis* are assigned by Meyrick to the year 1295. [SAINTE-PALAYE.]

In tournaments, when under the strict regulation of knightly usage, two sorts of arms were employed: those expressly made for the purpose, viz. lances with blunt heads of iron; and the ordinary arms of warfare, termed *armes à outrance*, which were employed only by such champions as were desirous to signalise themselves in more than ordinary degree, and frequently were not permitted by the judges of the tournament. Every knight attending was required to show his noble birth and rank, as a title to admission. These were at first proclaimed by the heralds with sound of trumpet; and hence the word BLAZONRY, which signifies the correct deciphering of the heraldic symbols on a coat-of-arms, is derived by some from the German blasen, *to blow*. Afterwards, when armorial bearings became general, the shield of the knight gave token of his rank and family. The attendance of ladies at the tournament, their distribution of prizes to those who had borne themselves best, arming and unarming the knights, &c., must not be supposed to have been the necessary, or even usual accompaniments of these knightly sports, at least until a later age, when the taste for gallantry, combining with that for show and spectacle, turned these military exhibitions of skill into little more than gorgeous pageants. When we arrive at the reigns of Edward III. and Henry V. we find the jousts usually held in honour of ladies, every knight being bound to possess in reality or in show a dame of his affections, for whose sake all these deeds of chivalry were performed. Sir. S. Meyrick quotes from a manuscript of the reign of Elizabeth the ordinances of jousts, made by John earl of Worcester, constable of England, in the sixth year of Edward IV.; from which it appears that the law of jousts had become by that time the subject of very minute regulation. The prize belonged to him who broke most spears 'as they ought to be broken;' i.e. on the head or body of the antagonist. From Stow we find that the lists erected in Smithfield in 1467, when the Bastard of Burgundy challenged Lord Scales, were 380 feet in length by 260 in breadth; these champions rode at each other two days with spears, and on the third encountered on foot with pole-axes. In the reign of Henry VIII., when the real spirit of chivalry was in its decline, the tournament was invested almost wholly with the character of a court pageant. Admirable accounts of these tournaments will be found in Hall's *Chronicles*. The famous volumes of woodcuts of the same period, styled the *Triumphs of Maximilian*, show that it was as favourite and almost as magnificent a spectacle at the court of Germany. The tragical death of Henry II. of France, in consequence of a blow received in a tournament, was the cause of the gradual abolition of this knightly amusement, which was revived at intervals in court solemnities in the seventeenth century, rather as a memorial of past times than as a subsisting and popular custom. (Sainte-Palaye, *Mémoires sur la Chevalerie*; Turner's *History*, 'Middle Ages,' vol. i. p. 472; *Hist. de l'Acad. des Inscr.* vol. xix.)

Tourniquet (Fr.). A bandage which may be tightened to any extent by means of a screw, so as to exert pressure upon a cushion and compress the arterial trunks to which it is applied: it is chiefly used to prevent hæmorrhage in the operations of amputation.

Tous-les-Mois (Fr. *all the months*). A kind of arrowroot obtained from the tubers of

some South American species of *Canna*—*C. glauca*, *C. coccinea*, *C. Achiras*, and *C. edulis*; the latter, a native of Peru, is believed to furnish the chief portion of that sold in the shops.

Tow (A.-Sax. teogan, Fr. touer). To draw a vessel along by a rope, either from another vessel or from the shore. As the vessel towed affects the motions of the other, much attention is required on her part to second the intentions of the towing vessel.

Towanite. A synonym for Copper Pyrites, after Huel Towan, a Cornish locality.

Tower (Lat. turris). In Architecture, a lofty building, square, polygonal, or circular on the plan, and often consisting of several stories. The tower of a church is that part which contains the bells, and from which the steeple rises.

Towers, Round. Edifices in Ireland varying in height from 80 to 120 feet, cylindrical in shape, with a door 8 or 10 feet from the ground, and with narrow apertures at the top. Antiquaries have been much perplexed in determining their date. They have accordingly been held by some to be temples built by Phœnicians, Persians, Buddhists, &c.; but the question has, in the opinion of some, been set at rest by the researches of Dr. Petrie (*Ecclesiastical Architecture of Ireland* i. 12), who has shown that they are simply detached bell-towers of Christian churches, built so as at the same time to be serviceable for defence in war. (Sir G. C. Lewis, *Astronomy of the Ancients*, p. 442.) The number of these towers in Ireland is sixty-two, and there are two in Scotland, at Abernethy and Brechin.

It is, however, maintained by others, that whatever may have been the purpose for which particular towers were built in Ireland or elsewhere in later times, these edifices are in their original idea phallic [PHALLUS]; that this idea is shown not only by their general form, which is found in countries altogether unconnected with each other, but by the mode in which their summits were finished; that towers unmistakably phallic, and exhibiting a striking resemblance to the Irish towers, are found in Cabul and other Eastern countries; and that these buildings further illustrate the raising of the Ashera on the Altar of Baal, and the combination of the LINGA and YONI in Hindu symbolism; and, further, that this idea furnished the model for church towers in general, these having originally existed in the shape of isolated campaniles (as is still seen in the Italian type), and invariably with a conical summit, which has been developed in the Gothic spire, a termination which, whether added or not, formed, according to A. W. Pugin, a necessary part of the design of all towers of every period of Gothic architecture.

Toxicology (Gr. τό τοξικόν, sc. φάρμακον, literally *poison for smearing arrows with*; λόγος, *a discourse*). Poisons have been divided into *irritants, narcotics*, and *narcotico-irritants*: the first class including those whose sole or predominating symptoms are those of irritation or inflammation; the second, those which produce stupor, delirium, and other affections of the brain and nervous system; and the third, those which are of a mixed character. Many irritants possess corrosive properties, and toxicologists have drawn a distinction between corrosives and purely irritant poisons. This is a modification of Orfila's original arrangement.

The chief effects of *irritants* are upon the alimentary canal, exciting inflammation, and sometimes ulceration, of the tongue, fauces, and œsophagus, difficult deglutition, nausea, vomiting, and heat and pain of the stomach, with more or less tension of the abdomen, and pain on pressure. The sickness is generally accompanied by extreme anxiety and anguish, and the matters vomited consist, in the first instance, of any food that may have been in the stomach, with portions of the poison itself, and afterwards of viscid mucus, often streaked with blood and tinged with bile; the pain afterwards extends throughout the intestines, and mucous, bilious, and often bloody diarrhœa succeeds. The skin is cold and clammy, the pulse quick and feeble, the breathing often difficult, and the countenance expressive of extreme anxiety.

Narcotic poisons induce a train of symptoms of a very distinct character: headache, vertigo, confused vision, stupor, convulsions, paralysis, and coma, are their leading effects; but each particular poison is usually attended by certain peculiarities in the succession, violence, or generic character of the symptoms, which assist the experienced practitioner not only in determining the nature of the poison, but in discriminating between its effects and those of disease.

The symptoms of the *narcotico-acrid poisons* usually consist of those of the two former classes blended, and are often of a very complicated character; for the most part, however, their narcotic and irritant effects appear to be incompatible. In large doses, narcoticism predominates; in smaller, irritation: it is rarely that both are coexistent.

In the following tabular view of the principal poisons of the above classes, the poisons are enumerated, with some additions, in the order in which they are described by Dr. Christison, to whose *Treatise on Poisons*, as also to that of Dr. Taylor, the reader is referred for details which would be quite incompatible with the space which can be allotted to the subject in this work. Under the heads of many of the individual substances mentioned in the following list, we have elsewhere given particulars respecting their composition and properties, and sometimes referred to their toxicological history.

I.—*Irritant Poisons.*

Mineral acids.	Arsenic and its compounds.
Phosphorus.	Mercurial compounds.
Acetic acid.	Salts of copper.
Oxalic acid.	Antimonial poisons.
Fixed alkalies.	Salts of tin.
Nitre.	

Alkaline and earthy chlorides.	Salts of gold.
	Salts of silver.
Lime.	Salts of bismuth.
Ammonia and its salts.	Salts of chromium.
	Salts of zinc.
Alkaline sulphurets.	Lead poisons.
Barytes.	Diseased and decayed animal matter.
Vegetable acrids.	
Cantharides.	Mechanical irritants.
Venomous serpents.	Certain poisonous gases.

II.—*Narcotic Poisons.*

Opium.	Hydrocyanic acid.
Hyoscyamus.	Carbazotic acid.
Lactuca.	Certain poisonous gases.
Solanum.	African ordeal bean.
Chloroform.	

III.—*Narcotico-acrid Poisons.*

Nightshade.	Strychnia.
Thornapple.	Cocculus indicus.
Tobacco.	Upas.
Hemlock.	Poisonous fungi.
Monkshood.	Poisonous grain.
Hellebore.	Alcohol.
Squill.	Ether.
Meadow saffron.	Empyreumatic oils.

Notwithstanding the apparently well marked line of distinction existing between the above classes, experience shows us that the substances arranged under each heading sometimes act very differently. Thus, arsenic and oxalic acid, both irritants, have been known to produce violent narcotic effects, such as coma, paralysis, and convulsions, especially when taken in full dose.

The treatment of cases of poisoning must, of course, vary with the nature of the poison, the quantity taken, and the peculiarities of the individual. In almost all cases, copious vomiting should be excited as soon as possible by tickling the throat and by emetics, especially sulphate of zinc. The latter, in 20-grain doses, dissolved in a little warm water and repeated every ten or fifteen minutes till it freely operates, is generally most effectual. The use of the stomach-pump may in some cases be resorted to. The vomiting should be kept up, and the stomach washed out with bland albuminous or mucilaginous fluids, such as milk, barley-water, flour and water, or thin paste.

The following is a short summary of the antidotes which may be resorted to, in reference to particular poisons. They should, of course, be administered as speedily as possible.

1. For *Mineral Acids*, or *Acetic and Oxalic Acid*:—Chalk, or whiting and water; magnesia and water; soap and water; followed by albuminous diluents, such as milk, and white of egg mixed with water.

2. *Alkalies, Soda, Potash, Ammonia, &c.*:—Vinegar, or any mild acid and water, or even very dilute mineral acids, such as water acidulated by them; olive oil, almond oil.

3. *Arsenic*:—Emetics; and then milk, gruel, thick barley-water, and other similar diluents, in large quantities. Hydrated oxide of iron and hydrate of magnesia have also been recommended.

4. *Corrosive Sublimate*:—White of egg and water; milk and cream; decoction of cinchona; infusion of galls.

5. *Sulphate of Copper*, and other *Cupreous Poisons*:—Sugar and water; white of egg and water.

6. *Antimonial Poisons*:—Warm milk, gruel, or barley-water; infusion of galls; decoction of cinchona.

7. *Nitrate of Silver*:—Copious draughts of warm salt and water.

8. *Sulphate of Zinc*:—Solution of carbonate of soda in water, with milk, and mucilaginous or farinaceous liquids.

9. *Acetate of Lead*:—Emetics; solution of sulphate of soda in water; milk; white of egg and water.

10. *Opium and its Preparations*:—Emetics; strong coffee; dashing cold water upon the face and breast; preventing torpor by forced exercise.

11. *Prussic Acid*:—Ammoniacal stimulants cautiously applied to the nose; ammonia, or sal volatile, in repeated small doses; small doses of solution of chlorine in water; small doses of chloride of lime in water.

12. *Strychnia* and *Vegetable Alkaloids*:—Infusion of gall nuts; decoction of cinchona; emetics.

Toxodon (Gr. *τόξον, a bow*, and *ὀδούς, a tooth*). An extinct genus of quadruped connecting the Pachydermal with the Rodent order, and distinguished by the curved form of all its teeth. The only known species (*Toxodon platensis*, Owen) was as large as the hippopotamus, and appears to have been restricted to the warmer parts of South America.

Toxotæ (Gr. *τοξόται*, from *τόξον*). In Greek Military History, bowmen. In the plays of Aristophanes, the toxotæ mentioned, like the French *archers*, are a kind of police, employed to keep order in the assemblies of the people and on other public occasions.

Trabea (Lat.). In Roman Antiquities, the robe used at first by the kings, but afterwards by consuls and augurs. The purple *trabea* was used only on the occasion of great sacrifices. The second sort, of purple and white, was commonly worn by consuls on state occasions. A third, of purple and scarlet, was the dress of the augurs.

Trabeation (Lat. trabes, *a beam*). In Architecture, the same as ENTABLATURE.

Trace (Fr.; Ital. traccia). In Fortification, the plan of a work.

TRACE. [DESCRIPTIVE GEOMETRY.]

Tracery, Window. The chief distinction between Gothic and all other forms of architecture is furnished by the window. In other styles the window is an excrescence, exhibiting little harmony with the rest of the design. In most of them it is a mere slit or aperture: in Saracenic and other Eastern styles, it is filled sometimes with an intricate network, which may deceive the inexperienced eye by its apparent resemblance to the tracery of Gothic windows,

But in all such cases the effect is much that which would be produced by a stamped pattern, in which the parts between the figures are perforated. Saracenic windows are thus mere reticulations, worked on a single plane, and cannot be placed in the same class with Gothic windows.

The complete idea of Gothic tracery requires not only that the lights and figure (or figures) above them shall be combined by label and arch, with mullions instead of portions of wall, but that the spandrils in the window-head shall be pierced. In the earliest Romanesque styles the window is merely a round-headed aperture, without the slightest attempt at combination; but in later examples these apertures may be found grouped in couplets or triplets. The first sign of the change which led immediately to the developement of tracery is seen in Kirkstall Abbey, where a circle appears above two arches without being combined by any external label or mark to show their relation, the portions of wall between them not being yet reduced into mullions and tracery bars (fig. 1).

Fig. 1.

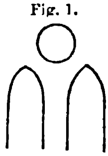

Fig. 2.

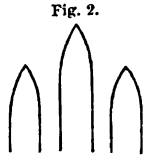

Fig. 3.

The earlier steps in this direction are exhibited in the triple arrangement of lancets (fig. 2), these being followed by the grouping of couplets, first apart (fig. 3), then united by a label over their different members separately (fig. 4), the wall

Fig. 4.

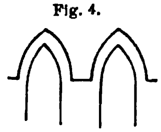

Fig. 5.

between them being then reduced to a mullion (fig. 5), and the couplet itself being afterwards included under one arch (fig. 6). The next step

Fig. 6.

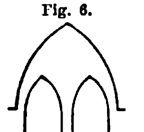

Fig. 7.

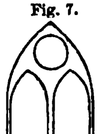

Fig. 8.

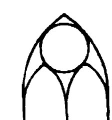

was to pierce the space between the couplet and the including arch (fig. 7), by the insertion of a figure which was almost universally the circle, the full developement of the idea of tracery being effected by the piercing of the spandrils (fig 8). It is scarcely necessary to remark that, in their primary developement into full tracery, the couplet and triplet present two very different types; and that while the triplet has influenced comparatively few windows, its own pyramidal form sufficiently filling the window-head (fig. 9), the greater beauties in tracery may be ascribed to adaptations of the couplet (fig. 10); so much so, that in three-light windows (fig. 11), the tracery

Fig. 9.

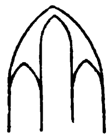

Fig. 10.

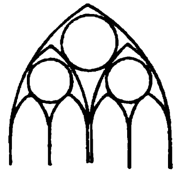

Fig. 11.

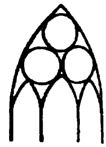

is formed by analogy from that which is seen in those groupings of two-light windows which furnish the designs of the most magnificent specimens of the geometrical period. In this style, the typical figure is the circle, pure geometrical tracery being restricted wholly to the use of this figure. This stage was followed by the employment of forms still geometrical, but showing later modifications: as the *vesica* (fig. 12), the *spherical triangle* (fig. 13), and the *spherical square* (fig. 14). Two-light windows in this style exhibit, therefore, simply a circle carried by the arches of the lights, while three-light windows are formed by analogy, three circles occurring in the head. In the latter, the central light is not unfrequently slightly higher and wider than the lateral ones (fig. 11), this being the only idea traceable to the early English triplet (fig. 2). It follows that windows of four and eight lights are formed by a repetition of the design of two lights. Thus, the great east window of Lincoln Cathedral (fig. 15), the most splendid of all pure geometrical examples, exhibits in the head a large circle (filled with seven smaller foliated circles)

Fig. 12.

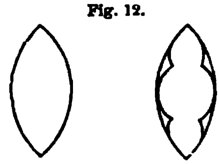

Fig. 13.

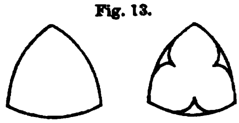

Fig. 14.

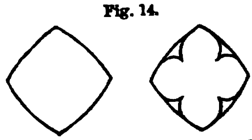

Fig. 15.

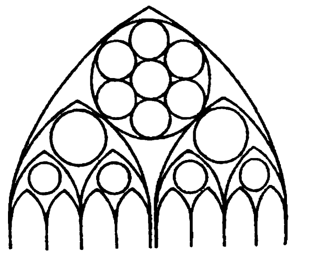
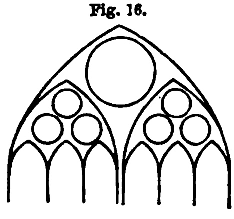


carried by two arches, which enclose, severally, a large foliated circle carried by two arches, which also contain a circle carried by two lights, thus forming the whole eight. Windows of six lights (fig. 16) have a circle in the head carried by two arches, enclosing fenestellæ or subordinate windows, each of which is filled up with the design of a three-light window. Windows with seven lights have similar fenestellæ, but a complementary light is introduced between them, on which, as well as on the fenestellæ, the circle is supported. Five-light windows have likewise a complementary light which carries the circle in the head, flanked by fenestellæ with the design of a two-light window.

Fig. 16.



The same relative design in the succeeding stage exhibits the triangle, the vesica, and in a few instances in England the square, conjointly with, or in place of, the circles of the earlier period (fig. 17). Foil figures also appear

Fig. 17.

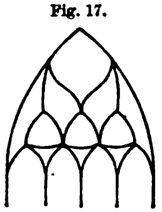


Fig. 18.

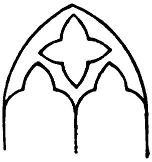

(fig. 18), i. e. the foliations of a circle or triangle are now seen as independent figures, the containing figure being knocked out. Both the arches and the tracery bars frequently assume this form, every succeeding developement of figure tracery being followed by a similar developement in foil tracery.

Thus far the great characteristics in the developement of tracery are: (1) the separate existence of the parts as opposed to the fusion apparent in the *Flamboyant* (fig. 19) and *Perpendicular* (fig. 20), and (2), as a consequence of this principle, the subordination of mouldings. In the continuous styles, so far as their nature is suffered to have fair play, the whole working

Fig. 19.

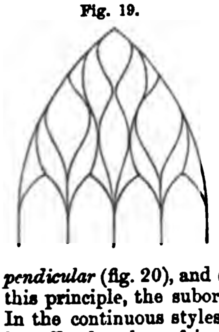

Fig. 20.

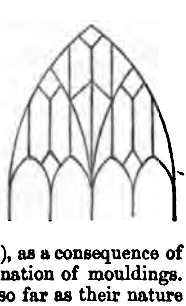

of a window is on one plane, whereas in the geometrical windows the primary mouldings are confined generally to the two principal arches and the circle which they carry, and where the number of lights is uneven, to the small subsidiary arch below the circle forming the head of the central light. The skeleton of the design being thus formed, the secondary mouldings develope the principal forms of the tracery, and define the outline of the foliated figures. In fact, geometrical tracery was never intended to do more than support itself; and the proof of this assertion is furnished by the fact that the tracery and mullions were almost invariably set after the window arch was completed, being designed only to fill the vacant space and carry simply their own weight; whereas, in modern work of the same style, it is not uncommon to see considerable portions of the mouldings of the window arch worked together with those of the tracery on the same stone.

The later styles are more complicated, and exhibit not merely a pyramidal piling but a fusion of parts, in which, instead of independent inserted figures, the tracery is formed of spaces bounded by lines continued from the mullions, not in an actually vertical direction, but ramifying towards different points (fig. 19). What the circle is to the geometrical, the vesica is to the flowing or flamboyant style. In practice, the combinations furnished in this style, often in conjunction with the preceding, are indefinitely various. Sometimes the skeleton is flowing, the filling up being geometrical, and vice versâ; and sometimes the head is geometrical, while the fenestellæ are flowing. The principle of flowing windows is the same as that of the continuous or perpendicular, however unlike they may at first sight appear. In both, the mullions are continued to the head, in the one in straight, and in the other in wavy lines. The notion of separate figures is gone: there is no subordination of mouldings, nor do we anywhere find vacant spaces. The later specimens of the continuous style in this country betray a tendency to revert to earlier forms, designs being in some instances produced in which the perpendicular line is entirely absent.

The developement of tracery brought about the foliation or *cusping* of the several figures contained in the design; and although the circle, vesica, triangle, and square are found uncusped (figs. 12, 13, 14), even in some elaborate windows (as at Grantham, in Lincolnshire), such instances are comparatively rare. These cusps seem to have originated in the idea of a figure filled with imperfect figures, part of the latter being knocked away: thus, at Oundle, four imperfect circles join a perfect circle, in the centre (fig. 21); if this perfect circle be removed, a cusped quatrefoil remains (fig. 22).

The cusp in foliations so obtained, assumed the form (fig. 22) known as the *truncated soffit cusp* (Paley's *Gothic Architecture*, p. 161); but the later and more common form is that

of the pointed cusp, which is exclusively used in the later styles.

The window tracery of the Continent follows essentially the same laws, although the transi-

Fig. 21.

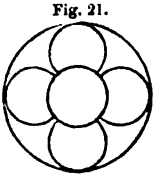

Fig. 22.

tion from the employment of mere round-headed apertures to fully developed tracery is more rapid, and marked by fewer intermediate steps than in this country. The English lancet style finds scarcely any parallel in Europe, and in Germany the spherical triangle and spherical square become more favourite figures than the circle or even the vesica. In England the flowing soon gave way before the perpendicular style; in France, as in Germany, the former took the strongest hold, and was developed (most luxuriantly in France) into the lavish gorgeousness of the flamboyant (or flame-like) style.

In Italy, as there was at no time a genuine Gothic style, so the forms exhibited in the tracery of windows are mere imitations of the forms employed by the northern architects, by whom many of the finest Italian buildings were designed. In the *Renaissance* styles no attempt has been made to develope any new forms of tracery, and for the most part they have not employed this feature at all, the windows being again reduced to mere apertures, which not unfrequently disfigure the whole design. (Freeman *On the Origin and Developement of Window Tracery in England*; Sharpe's *Rise and Progress of Decorated Window Tracery in England*.)

Trachea (Gr. τραχεῖα, from τραχύς, *rough*). The windpipe. A cartilaginous and membranous tube through which the air passes into and out of the lungs. Its upper extremity is called the *larynx*, and consists of five cartilages. The uppermost forms a kind of valve at the mouth of the larynx or glottis, and is called the *epiglottis*: it closes the passage in the act of swallowing. The sides of the larynx are formed by the *arytenoid* cartilages, and the anterior part of the *thyroid* and *cricoid* or annular cartilages; these may be felt under the skin in the front of the neck. These cartilages are united by elastic ligaments, and are acted upon by appropriate muscles, so as to modify the dimensions and form of the aperture in the act of speaking: they are moistened by a mucous secretion. The canal from the larynx downwards is called *trachea*, till it divides into two *bronchiæ* opposite the fourth or fifth dorsal vertebra. They are kept open for the free passage of the air by their elastic cartilaginous texture, which consists of rings with intervening membrane and muscular fibres.

Tracheæ. In Botany, the spiral vessels of plants, which received that name because they were regarded as the respiratory tubes of plants. *Trachenchyma* is a tissue composed of tracheæ.

Trachearies. The name of an order of the class *Arachnida*, including those which breathe by means of tracheæ.

Trachelidans (Gr. τράχηλος, *a neck*). The name of a family of Coleopterous insects, comprising those which have the head supported on a kind of pedicle or neck.

Trachelipods (Gr. τράχηλος, and πούς, *a foot*). The name given by Lamarck to an order of Molluscs, comprehending all those which have a free and flattened foot attached to the under side of the part of the body which he considers as analogous to a neck. The order corresponds nearly with the Pectinibranchiate Gastropods of Cuvier.

Tracheocele (Gr. τραχεῖα, and κήλη, *a tumour*). A tumour upon the trachea; an enlargement of the thyroid gland. [Bronchocele.]

Tracheotomy (Gr. τραχεῖα, and τέμνω, *I cut*). The operation of making an opening into the trachea in cases of threatened suffocation.

Trachinus (Gr. τραχύς, *rough*). A genus of spiny-finned fishes, characterised by their compressed body and approximated eyes; two dorsal fins; the first short, and with spinous rays; the second long, and with flexible rays. The anal fin is very long; the operculum is armed with a long spine directed backwards. By the wounds which the species of *Trachinus*, usually called *weevers*, inflict with their opercular spine, they have become formidable to fishermen of all nations; and it is said that the French have a police regulation, by which the fishermen are directed to cut off the spines before they expose the fish for sale.

Trachitis. Inflammation of the trachea.

Trachyte (Gr. τραχύς). A variety of lava which is often porphyritic, and when containing hornblende and augite passes into the varieties of trap called *basalt*, *greenstone*, *dolerite*, &c.

Tract, Treatise (from Lat. tractatus). It would be difficult to assign any reason for the difference in signification between two words identical in origin and etymological meaning; but the first is now commonly used to describe short compositions, in which some particular subject is *treated* generally in the form of a pamphlet; the latter, more extensive works.

Tractarians. In Modern Church History, a party name given to those members of the church of England, chiefly from the university of Oxford, who headed the theological movement which definitely took shape in 1833. (Newman, *Apologia pro Vitâ suâ*, p. 100, and passim.) The celebrated *Tracts for the Times*, from which the appellation is derived, began to appear in that year: the knot of writers who produced them being chiefly actuated, in the first instance, by hostility to the Whig

government in its measures, commenced or apprehended, for the reduction of the Church establishment in England and Ireland. But their purpose soon diverged to the wider scope of re-establishing High Church doctrine and practice on the level of the school of Laud and Andrewes. The *Tracts* continued to appear occasionally, until some of them, culminating in Mr. Newman's celebrated *Tract No. XC.*, indicated plainly a tendency to coalesce with Rome. This tract appeared in 1841, and excited a storm of opposition, under which the *Tracts* ceased to appear, and one of the two recognised leaders of the party (Mr. Newman) in no long time submitted himself to the church of Rome.

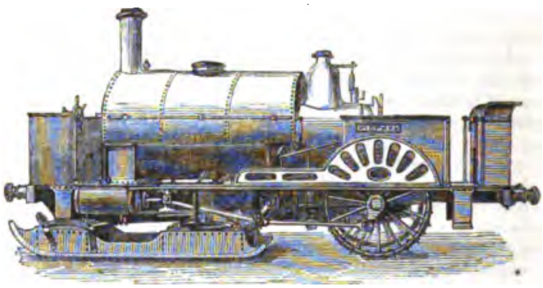
Traction Engine. A species of locomotive engine for drawing heavy loads upon common roads. Before the general introduction of the railway system, steam carriages, capable of maintaining a speed of twelve or fourteen miles an hour, were proposed in substitution of the common horse coaches; and several steam carriages of this character were constructed and tried. But the rapid extension of the railways extinguished this traffic, and all idea of achieving high rates of speed by locomotives on the common road has been abandoned, in countries at least in which railways exist. But a species of steam waggon, called a *traction engine*, has latterly been introduced for drawing heavy loads upon common roads at a low rate of speed, and such steam waggons are also used for steam cultivation and for all the purposes of threshing, sawing, and pumping, to which the common agricultural engine is applied. In drawing heavy weights, traction engines have this special feature of advantage over horses, that whereas it is difficult to get the horses to start or stop, or pull together, the engine power can be managed with the greatest facility. Traction engines are consequently much used for drawing boilers, guns, and other heavy weights.

One of the earliest forms of traction engine is that known as Boydell's, to the wheels of which are fitted chains of boards forming a species of endless railway, which the engine lays down and lifts up as it proceeds, being thus enabled to travel over soft ground. Engines of this kind have been employed to traverse a field drawing rows of ploughs behind them, and a whole furrow has thus been ploughed up at once. Another form of traction engine is that known as Bray's, in which the wheels of the engine, which are made very wide, rest on the ground; and to prevent the driving wheels from slipping when rotated, sliding plates or grippers are projected through the tire of the wheels by central eccentrics, which projections gear with the ground and compel the waggon to advance. Most of the makers of agricultural engines also construct traction engines, which are so made that they can perform the general work of the farm, and at the same time draw the agricultural produce along the roads. These traction engines are for the most part constructed with a single cylinder, lying on top of the boiler; and gearing, and also very frequently a pitched chain, is interposed between the engine and the driving wheel, so as to enable the engine to develope its power by moving fast while the driving wheel rotates at a moderate speed. The traction engines of Aveling and Porter, Clayton and Shuttleworth, Garret and Son, Robey and Co., and most other makers, conform to this general description. But Robey and Co. have also a highway locomotive with large wheels, which is intended to maintain on the common road higher speeds than their traction engine is capable of. In Chaplin and Co.'s traction engine, as constructed in 1866, the boiler is vertical and is fitted with Field's tubes, which are blind tubes, hanging from the top of a high fire-box, and each fitted with a smaller internal tube through which the water descends, while the steam and water ascend round the annulus, an efficient circulation being thus maintained. The carriage is fitted with side frames, as in a locomotive, to which the cylinders, seven inches in diameter and fourteen inches stroke, are bolted. The crank shaft carries three malleable cast-iron pinions, each of which can at pleasure be placed in gear with a corresponding spur-wheel, also of malleable cast iron, fixed upon a countershaft; and each end of the countershaft carries a pinion, which gears into wheels with internal teeth attached to the driving wheels. By suitable clutches, either driving wheel may be driven or thrown out of gear; and by shifting the suitable pinion on the countershaft, so as to gear with its corresponding wheel while the others are placed out of gear, the carriage may be propelled at the rate of two, four, or eight miles an hour. The exhaust steam, instead of being discharged in puffs up the chimney, is discharged into a tank or reservoir placed between the frames, whence it escapes up the chimney in a continuous stream. The driving wheels are six feet in diameter and fifteen inches wide in the tire, and projecting grippers or spades may be projected through the rim to gear with the ground, as in Bray's plan. The carriage is fitted with springs as in locomotives.

There are many countries in which traction engines would be of great value, from the existence of good common roads, the scarcity of railways, and the trying nature of the climate to animals employed for draught. In 1866 measures were taken to establish such engines on the road leading from Beyrout to Damascus, in Syria, a distance of sixty-eight miles. These engines have been constructed by Messrs. Dübs, of Glasgow, from the designs of Mr. Clarke; and as they have to surmount the Lebanon and Anti-Lebanon ranges, they are intended to draw ten tons of goods over inclines rising one in twelve, at the rate of from three to five miles an hour. The general arrangement of the engine resembles that of a locomotive. The driving wheels are furnished with Bray's teeth; but they are made hollow to enable the actuating rod to be attached to the

bottom of the tooth, instead of to its inner end, the tilting action before experienced with that apparatus being thus prevented. The engine carries 500 gallons of water and 15 cwt. of coal, and when tested, in July 1866, was found to perform all that was expected of it.

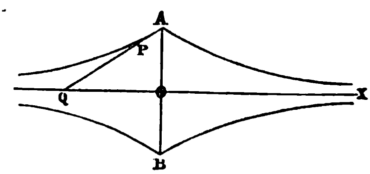
An interesting application of the traction engine for running upon ice, is represented in the annexed figure. This engine was constructed by Messrs. Neilson of Glasgow, and is reported to have been successfully employed in conveying goods and passengers on the Neva between St. Petersburg and Cronstadt during the winter months. The front part of the engine rests on a sledge, which is capable of being moved round a centre by a pinion gearing into a segment, and worked by the steering wheel shown at the front, which gives



motion to an endless screw gearing with a suitable wheel, which turns the spindle of the pinion round with great force; and by swivelling the sledge—which, however, would be better done by a small engine—the machine is steered. The after part of the engine rests upon two driving wheels 5 feet in diameter, the peripheries of which are studded with steel spikes to grip the ice. The cylinders are of 10 inches diameter and 22 inches stroke. The weight of the engine is 12 tons, and it realises a speed of 18 miles an hour. It will be proper in such an engine to apply a shelving edge on each side of the sledge, so that its swivelling may not be prevented by sinking somewhat into the ice or beaten snow; and to the same end the swivelling gear should be powerful, and under easy and rapid control under the worst circumstances likely to occur. In Russia and in Sweden extensive lakes and other tracts of water, being frozen in winter, are available for the application of such an apparatus. But in some of the lakes there are warm springs which create holes in the ice; and the desideratum to be aimed at is to render available the little vessels which ply in summer for plying also in winter by mounting them on a sledge, as was proposed by Mr. Bourne to be done for some lakes in Sweden in 1847.

Tractors, Metallic. Small bars of metal which were supposed to possess certain magnetic powers, and to cure painful affections and tumours by being drawn over the part. They bore the name of their inventor, Perkins, and were much used about thirty years ago. A number of wonderful cures, however, having been attested, which were performed by means of spurious wooden tractors, the imaginary virtues of the magnetic or metallic fell into disrepute, and were soon forgotten.

Tractrix (Lat. traho, *I draw*). A transcendental curve possessing the pro erty that the portion P Q intercepted upon every tangent, between the corresponding point of contact P, and a given fixed line O X, has a constant length O A = *h*. It belongs to the family of equitangential curves, and evidently consists of four



symmetrical branches having the given line as asymptote and two cusps at A and B. Its equation is readily found to be

$$x = h \log\left(\frac{h+\sqrt{h^2-y^2}}{y}\right) - \sqrt{h^2-y^2}$$

Its evolute is the catenary. [CATENARY.]

The name *tractrix* or *tractory* was given to the curve by Huygens, who conceived it to be generated mechanically by a small weight P attached to a string P Q, the other extremity of which is drawn along the fixed line X Q. (D'Alembert, *Encyc. Méthodique*; Peacock's *Examples*; Salmon, *Higher Plane Curves*.)

Trade (Ital. tratta). The exchange of commodities between town and country, producer, dealer, and consumer, nation and nation. Trade is either home or internal, or foreign.

The origin of trade is contemporaneous with the earliest civilisation. Mutual needs bring about mutual exchanges. In time, this humanising communication extends to other countries, and would be general if the evil passions and selfish interests of men did not interfere to check or hinder the developement of these reciprocal benefits. Either from what is called public policy, and which generally means the cultivation of jealousies between states supposed

to be rivals in ambition, the intercourse which the instincts of men suggest, is impaired; or in deference to the influence of certain classes who fear rivals in production, and who are able to control the commercial interests of a nation, protective or prohibitive arrangements are made, and the course of trade is diverted from its natural course to unprofitable channels. [FREE TRADE; PROTECTION.]

The extension of trade, in the absence of these unnatural restrictions, is limited only by the width of the market; and the market becomes wider, in so far as the means of transit or carriage are rendered cheaper and more regular. The cost of carriage is diminished partly by the developement of mechanical arts, partly by the practical study of physical geography. Thus the art of shipbuilding, and of engineering by land, though we cannot assert that they have reached perfection, are improving yearly; and as the physical peculiarities of the sea, the currents, the prevailing winds, and the like, are better known, the cost of sea passages is diminished by the diminution of the time needed to perform them. So, again, the power of establishing such communications as shall insure a rapid and exact knowledge of the markets, is of great moment in securing that uniformity of prices, and diminution in the risks of trade, which constitute to the consumer no small part of the cost of such commodities as he needs. Speculation, i. e. the disposition to purchase in the hope of a rise, though of great importance as an economical process in regulating the price of the *first necessaries* of life, is a great evil in such branches of trade as deal with the *conveniences* of life, because in so far as it operates on prices, it tends to exalt them by increasing the risks of the dealer and the supply to the consumer.

The French economists, of whom Turgot and Du Quesnay were the most ancient, entertained the notion, that of all kinds of trade, agriculture was the most advantageous, manufacture being placed next, and commerce last. This view, due in no small degree to reactionary feeling against the mischievous policy of the French government, was embraced by Adam Smith (book ii.), and forms one of the chief errors in his great work. It is plain that the advantage or disadvantage of any trade, if exchange be free, is determined by present, and not by abstract considerations.

The growth of trade in this country is due, partly to the early adoption of the principles of free trade, and the abolition of restrictions; partly, we may perhaps say, to the energies of the people, and their adventurous temper; not a little to the fact, that this country, being insular, and possessing a singularly large number of accessible harbours, is also under these conditions the commercial centre of the largest and most fully occupied part of the earth's surface. [COMMERCE; EXCHANGE; GEOGRAPHY, POLITICAL; PRODUCTION; ROUTE, COMMERCIAL.]

Trade, Board of. A branch of the Privy Council, properly styled Committee of the Privy Council for Trade and Plantations. This body originated under Charles II., and its history is satirically described by Burke in his speech on economical reform. It was, he says, 'a showy and specious imposition,' reproduced 'as a job' on an occasion of distressed trade in 1696, 'to quiet the minds of the people;' and 'perhaps,' he adds, 'it is the only instance of a public body which has never degenerated.' Once more reconstituted in 1786, it continued as a body of rather anomalous functions, but chiefly useful in practice to assist other departments of state by answers to references on questions connected with the trade of the empire. Of late years, however, various statutes have conferred on it important functions of administration. It has extensive powers for the control of merchant shipping and seamen; a supervision over railways, transferred to this board in 1852 (14 & 15 Vict. c. 64); it registers joint-stock companies since 1858 (19 & 20 Vict. c. 47; 25 & 26 Vict. c. 89), superintends the coal trade of the port of London, &c.

Trade Mark. One of the greatest risks which the trade of any country can run, is that of dishonesty or fraud on the part of producers or dealers. Over and over again, successful branches of commerce have been ruined by the fraud of persons who have pretended to supply goods of equal merit with those to which purchasers have been habituated, but have supplied inferior or useless articles. A singular illustration of this fact is given in the late report of Birmingham industries, p. 273: 'Immense quantities of a species of money, known as Manillas, were at one time produced in Birmingham by casting. It was exported to the Spanish settlements on the Old and New Calabar and the Bonny rivers in Africa.. In an evil hour, however, a sharp trader, not a little unscrupulous. animated by a desire to become speedily rich, conceived the brilliant idea of producing these objects in cast iron, and coppering them over by the electro-deposit process. On their arrival at their destination the deception was at once detected. This gave the quietus to the manufacture of "Manilla" money in Birmingham till very recently.' The author goes on to state the precautions which the negroes take to test the small quantity which they now receive. Over and over again, it has been found impossible to establish trades, because no valid security can be given that agents and intermediate dealers will be honest. The correction to these vices, which always react on those who practise them, may be hoped for partly in the spread of moral principle and an enlightened interpretation of what constitutes real self-interest, partly in the effectiveness of private and public police. The latter of these methods of repression is not necessarily operative, for it is not always easy to be sure of the integrity and activity of those who are appointed to watch over the administration of law; the former is to some extent satisfied by the use of *trade marks*, and the interest which honest producers

have in securing themselves against forgery of the symbols adopted by them in order to distinguish their wares from those manufactured by rival houses.

These symbols are known as trade marks, and the custom of using some such marks has become almost universal among those traders who believe that such an advertisement is at once a means for diffusing the knowledge of their goods, and of protecting themselves from fraudulent imitations.

The earliest of these marks appear to have been those which were used in the manufacture of paper; and of paper water-marks, the earliest appears to be on a document bearing the date 1351, i. e. shortly after the invention of paper from linen rags. Trade marks have also been used for a long time on cutlery; and in some cases, as in the ancient statutes relating to wool, the use of a trade mark has been recognised by Act of Parliament.

Trade marks have, however, been very commonly forged or counterfeited, and the Court of Chancery has in numerous cases been called on to interfere by injunction for the purpose of restraining this practice. By a recent statute (25 & 26 Vict. c. 88), frauds of this nature have been made punishable by fine and imprisonment.

Trade Winds. Winds which in the torrid zone, and often a little beyond it, blow generally from the same quarter, varying, according to circumstances, from N.E. to S.E.

The cause of this wind is to be ascribed principally to the high comparative temperature of the torrid zone, combined with the rotation of the earth from W. to E. As the heated air at the surface ascends into the higher regions of the atmosphere, its place is supplied by the colder air rushing from the poles. This colder air, also becoming rarefied, ascends in its turn, and is carried in the upper regions towards the poles to supply the stream of the under current; and these under polar currents moving in progress towards the equator from the zones where the earth's motion is slower to others where it is more rapid, acquire an apparent relative motion in a westerly direction. As the currents from the two hemispheres meet near the equator, their meridional motions are there destroyed, and they therefore advance together with the remaining motion from the eastward round the globe. The regularity of the trade winds is disturbed in some places by local causes, and chiefly by the superior rarefaction of the air over land heated by the sun's rays. They extend farther to the northward or southward according as the sun's declination is north or south; and in some places they become periodical, blowing one half of the year in one direction, and the other half in the opposite one. [MONSOON.] In the great Pacific ocean, however, the trade wind blows with a uniform and gentle breeze all the year round. The name of *trade winds* was given to them from their important influence in commerce, expressing, as they do, the '*wind blowing* trade.'

Trades' Union. An arrangement or combination entered into by the workmen of particular trades, or manufactures, in order to regulate the prices of labour, the hours during which labour is employed, and not unfrequently the number of workmen engaged by an employer, the number of apprentices bound to the employer or his foremen, and the number of journeymen. The purpose of a trades' union is, therefore, the settlement of the proportion which wages should bear to profits. The effectiveness of a trades' union depends on: (1) the esprit de corps of the workmen themselves; (2) moral restraint; and (3) unfortunately, when men's passions are heated, coercion exercised on those who are unwilling to join the trades' union or are indifferent to its real or supposed advantages; and (4) failing the consent of the employer or general body of employers to the demands made by workmen, the last remedy of a *strike*. Of late years, the association of workmen for these purposes has occupied a considerable amount of public attention, and even alarm, although no one has ventured to suggest that such combinations ought to be repressed by authority, while many have asserted and argued that a trades' union, with all its machinery (short, of course, of coercion), is a natural expedient, and a legitimate defence against wrongs which it is presumed may be inflicted on labour by the power of capital.

Before 1825, combinations between workmen for the purpose of raising wages were treated as conspiracies, and were punishable by a variety of statutes. The history of these statutes is important and well defined, and if it were granted that a combination is economically and socially indefensible, it would still have at least an appearance of equity, because it was a natural reaction against wholly inexcusable acts of the legislature.

The inevitable consequences of the great plague of 1348 (for the labour statutes of English law date from the second year after that great event) were a rise in the price of labour, sometimes to double its previous rate, almost invariably to seventy per cent. The reader may see the evidence, extracted entirely from contemporaneous records of farm and other accounts, in the first two volumes of Prof. Rogers' *History of Agriculture and Prices in England*. In order to check this rise, a statute was passed in 1350, which attempted to prevent any change, by fixing the rate of wages and by levying penalties on those who paid or received more than the old rates. It is almost unnecessary to say that the legislation was inoperative, and that high prices of labour, despite the law, were demanded and paid. But the statutes of labourers were enacted in one form and another over and over again, and with fresh provisos, or with new machinery, intended to secure the objects of the law. Meanwhile, as the price of labour rose and fell according to those natural causes which exalt or lower wages, the law, on some occasions, was

apparently effectual, while a strong impression was left on the minds of labourers that the various statutes really checked or controlled the rate of wages. If, therefore, we are disposed to criticise the action of servants or labourers in combining together for the purpose of raising wages, we should remember that for 475 years the whole force of the legislature, stimulated by the perpetual complaints of employers, was directed towards the depression of wages by artificial means. The means employed were wholly or nearly nugatory, but the intention was reasonably looked on as the same as the deed, and it was difficult to believe that all this force was wasted, and all these statutes futile.

In truth, throughout the whole economical history of England, these laws have, it seems, failed of producing the slightest real effect. They may, perhaps, have occasionally enabled an employer to break his contract, they may have been vexatious and alarming, but they never affected the average rate. Wages were very high, as estimated by the price of food, in the two hundred years between 1350–1550, and fell considerably between 1550–1700; rose again between 1700–1760; fell again till after the peace of 1815, and have been on the whole steadily rising since. These changes, however, have not been, as we might expect, brought about by any law, ordinance, statute, or proclamation, but simply and solely by those economical causes which, under the formula of supply and demand, fix the prices of labour as they do the prices of anything else.

When, however, the statutes enacted in the interest of employers were abolished, the laws checking combinations being at the same time relaxed, it was natural that such combinations should be entered into. But it may be doubted whether any such arrangements would have been made, or, if they had been made, would have spread, or have obtained the least share of public sympathy or approval, or would have warranted the fundamental assertion of a trades' union that it is necessary to protect the workmen against the tyranny of capital, had it not been for these 475 years of unjust, vexatious, and selfish enactments.

The operation of a trades' union, and its purpose (viz. the regulation of wages by other arrangements than the natural action of supply and demand), may be considered either in relation to the workmen themselves, in relation to the employer, in relation to labour generally, or in relation to the public, i.e. the purchaser of those commodities or utilities which are affected by a union. But to make all these efforts clear, it is necessary to say a word about the fund from which wages are paid, i.e. floating capital, or the labour fund.

The source of wages is capital. Without it there could be no employment. Capital is accumulated with a view to profit. If sufficient profit is not attained, capital ceases to be collected, and in such a case, labour is no longer employed. Whatever, then, be the demands of labour, they cannot supersede profit. Hence, if by any machinery certain classes of workmen contrive to appropriate a larger share of wages than other workmen, or more than they have hitherto received themselves, they must either obtain a portion of that which would otherwise go to other labourers, or they must raise prices. They must either mulct the labourer or the consumer. They will partially lay a loss on both.

It may be doubted, however, whether any such machinery will really raise wages. Few strikes have been successful, and those which have been most prolonged have generally been followed by a resumption of work at old charges; and though it is asserted that the dread of a strike has induced masters to advance the rate, it may be questioned whether the demand for labour would not have effected this advance by itself. No rates of wages have risen like those of domestic servants, especially those of females. But combination, or any mutual arrangement with a view to raising wages among domestic servants, has not only never existed, but is manifestly out of the question. Nor does it follow that persons will readily find out the futility of plans in which they place an undeserved confidence. It has been found over and over again that protection is no real aid to industry, long before protected industry has discerned the delusion for itself.

But though the machinery of a trades' union may not raise wages, it may affect labour itself. The organisation which attempts to secure labour its rights must extend its aid to all the labourers who are leagued in the union. Hence the common reproach against trades' unions, that it depresses the best workmen to the level of the worst, and thus renders labour ineffective. The same result would seem to follow from such regulations as those which prescribe, for instance, the way in which a bricklayer should work, and the attendance which he should have. A rule of this kind, and other similar rules, may not have the effect of raising wages, but may raise prices by raising the cost of production. That these rules have this effect may, it appears, be proved incontestably by testing the rate of wages at different times, and comparing the cost of, say a building in an ancient bill, with a modern estimate for the same work.

Suppose, then, that labour is rendered less effectual, the labourers who enter into these arrangements may injure other labourers in two ways without benefiting themselves. They may appropriate, by an undue number of hands, a larger share of the common fund than would fall to their lot if the arrangements were wholly free, and they may make the article which they produce, and which may be used, and commonly is used, by those who are unable to combine, dearer, and therefore more inaccessible. To illustrate this in a simple way, suppose a cottage costs under the present system 150*l.*, and that 50*l.* of this sum is added by the fact that labour is less effectual than it would be in the

absence of trade regulations. Fifty pounds' worth of labour is appropriated by the building trades, while it might have been spared for other labour, and the cottager has to pay interest in the shape of rent on 150*l.* when he might have had to pay it on 100*l.* only. If some part of the wages are appropriated in this way it must be to the detriment of other labour, for a general rise in labour is as absurd as a general glut, or a general rise in values.

It is said that capital is tyrannical. Now there is no economical truth more certain than that profits tend to an equality. But by tyranny must be meant an attempt to secure greater profits by grinding down workmen. If greater profits were temporarily attained, it is impossible to keep the secret, and competition will soon reduce them. If by tyranny, however, is meant a constant watchfulness, and perhaps occasional harshness, in attempts on the part of the capitalist to save himself from the risks of a strike, it is hardly just to call that a tyranny which is retaliatory or perhaps a mere act of self-defence, and certainly the capitalist will not run these risks unless he is tolerably certain to save himself, either by prompt action with his labourers, or by increased charges to the public.

We have said that a general rise in wages is out of the question, and by implication, that a universal trades' union would defeat itself. As a rule, then, a union is most powerful among such mechanics as are occupied in supplying the second necessaries of life, and especially in the building trades. But they who join the union cannot avoid using that which they produce; and provided there be no real rise effected in the rate of wages by the union, while the price of the commodity is enhanced by the regulation, it seems that the labourer can only gain a loss by the arrangement which he makes. Now a rise in the price of the second necessaries of life always falls heavily on persons with narrow incomes. If two persons have respectively 100*l.* and 1,000*l.* a year, the cost of house rent will represent a higher per-centage in the former than it does in the latter case. It is clear, then, that the effect of a trades' union on general labour, and its effect on the customer or consumer, is by no means beneficial.

The outrages and persecutions which generally disfigure trades' unions and strikes are not a necessary feature in this organisation, but a natural sequence. If workmen believe that a trades' union benefits them, they necessarily look on the man who stands aloof as disaffected to the interests of their order, and if he takes employment when men are on strike, he is regarded as a traitor to the working man, and a hindrance to the purposes for which the strike was organised and directed. When the etiquette of professional practice is so strong and its social police so stringent, we can hardly wonder that working men should adopt their process of energetic excommunication against those who discredit or weaken their cause.

To those who are but slightly acquainted with the principles of political economy, it will be clear that the origin of these combinations is to be found in an excess of labour over capital (for in times when labour is in demand we hear nothing of this organisation), and that the state of things becomes chronic by reason of the improvidence of workmen. If the means of any artisan enabled him to say that he would find elsewhere a market for his labour (and in the great majority of cases such a market does exist) when the home demand fell short, he could readily attain the maximum for his wages which the market will bear. There cannot be, in the nature of things, any reason why labour should not assert a right which capital (the employment of which is only another kind of labour) cannot assume, i.e. the right of being employed in a particular locality, or at least on fixed terms.

But, in effect, the remedy is in the hands of working men to a far larger extent than they imagine. The true solution of these apparent relations between labour and capital, is to unite them in the same person, i.e. to adopt the practice of co-operation. A union of fifty or a hundred workmen, with an aggregate of all their capitals in a building company, would do more to determine for them the true relations of the above-named economical elements, than all the unions in existence. There can be no more reason why a workman should not be possessed of capital for his own craft, than there is that a trader or a professional man should not have it. Accordingly, it appears that trades' unions in many quarters are now looked on by working men with disfavour, and with doubts as to their real efficacy; and that emigration and co-operation, the one abroad and the other at home, are becoming extensively popular.

Meanwhile, the losses which labour and capital have suffered in these battles of endurance have led both parties to attempt conciliation by appointing arbiters in cases of dispute. To the credit of the artisans it should be said that they have been far more willing to submit to this arrangement than the capitalists, who resisted this rational measure during the time of the nine hours' movement of 1862. Such a scheme has been long known in France, under the name of *conseils des prudhommes*, and it may be hoped that similar means will be adopted in this country. [COMBINATION.]

Tradition (Lat. traditio, *a handing down*). In History, this term is generally applied to narratives or statements relating to alleged events, which have not been preserved in documents contemporary with the period of which they profess to speak. Like all written historical narratives, the subject-matter of tradition must be estimated by the measure of credibility due to the original witnesses, and by the degree of fidelity with which their testimony has been preserved. It is scarcely necessary to remark, that when statements, handed down by oral tradition, have been reduced to writing at a time long subsequent to that in which the events are stated to have

occurred, the character of the narrative is in no respect altered, and the statements remain strictly the result of oral tradition and not the result of written contemporary history.

Oral tradition is thus separated from all contemporary historical documents. It is unconnected with the evidence of inscriptions on public monuments, the registers of magistrates, or written genealogies, or a written chronology. The tests for measuring the value of these various sources of information are given in the article Historical Credibility; and as these tests all involve the paramount need of known contemporary and trustworthy witnesses, it is obvious that statements coming to us from alleged witnesses whose words were not reduced to writing at or near the time to which they belonged, must be subjected to an unsparingly rigorous scrutiny by all who wish to arrive, not at possible pictures of events which may have taken place, but at the actual truth of facts. In other words, oral tradition must, as such, be regarded with grave suspicion.

It must, however, be admitted that the oral traditions of one nation may be far more deserving of credit than those of another. In states of society which are permanently fixed by clanship, or by the spirit of feudalism, and in which consequently the bulk of the population is tied to the soil, local traditions may be maintained with a fidelity for which it is vain to look in conditions of society under which popular sentiment is continually changing. By the nature of the case, all oral traditions are liable to modification by the colouring thrown over them by the narrator, and this colouring must vary with every deviation from the sentiment or conviction of the original witness. In this respect, the sons or grandsons of those among whom a tradition is established stand on a footing differing indefinitely from that of their predecessors. On those with whom they are brought into personal contact, the motives and words of men are more deeply impressed than the results which may be produced by them; but a later generation is, in constantly increasing measure, tempted to forget their words and motives, while it retains a fair recollection of the objects which they attained or sought to attain. The details of each narrative become gradually weaker and more faint, until not unfrequently there remains only some barren statement which has lost all life and meaning. Thus the force of oral tradition is weakened with each successive generation. In countries where there is no written history, the sons know a good deal about the incidents in the lifetime of their fathers, a little about the fortunes of their grandfathers, and next to nothing of the events of a more remote age. In an age of written history, on the other hand, the time which a little precedes our own birth is generally that with which we are least familiar. Its records have not yet been thrown into their permanent historical form, while the chief actors are passing away from the scene, and the mass of original documents out of which the history of their acts is to be compiled are commonly far too bulky and too inaccessible to allow of much acquaintance with them, except within a comparatively small range. But the existence of these original documents is a guarantee against all those distorting influences (of personal motives, of jealousy, and admiration, of sympathy with a winning or a losing side) which are perpetually at work with ordinary oral tradition, and which tend to deprive us of all confidence in narratives orally handed down, except under certain conditions.

These conditions depend on the form in which the narratives are presented. Traditions, which may be regarded as the mere hearsay of a people, are constantly undergoing modification or corruption, from which they are comparatively free when thrown into a metrical form. We have no reason, apparently, for thinking that the Homeric poems contain any genuine history of early events in Greece and Asia Minor, but the compositions of the poems added indefinitely to the strength and permanence of the traditions embodied in them. Stories which, like the tale of Thersander and Attaginus (Herod. ix. 16), come to us through the medium of ordinary conversation are worth comparatively little; but the metrical form of poems popular amongst many friendly or antagonistic tribes insures, by the very strength of their mutual attachments or jealousies, a transmission which, with allowances made for trifling verbal alterations, may be regarded as thoroughly trustworthy. Apart from this guarantee, the preservation of the most beautiful legends becomes a matter of great uncertainty; and indeed it may be said that a change in religious sentiment, or the introduction of a new standard of criticism, will insure their destruction, except in so far as they are counteracted by that portion of the population which is free from such influences. If the tale of Troy had not been thrown into a metrical form, and if all his contemporaries without exception could have been brought to believe with Herodotus that Helen never went to Troy, but was detained at the court of the Egyptian king, it is certain that the whole legend of Achilleus and Agamemnon, of Paris and Hector, must have utterly perished, or have been preserved in a form wholly unlike that in which it is recorded in the *Iliad* and the *Odyssey*.

Again, in an age of unwritten history, national epics are regarded with a religious veneration, and the memory, not distracted with the manifold interests of a complicated civilisation, acquires a strength which to members of modern commonwealths seems incredible. Even in the time of Xenophon, Athenian citizens were able to repeat the whole *Iliad* and *Odyssey*, and the task must have been far easier when the whole story was

still received with a profound religious faith. This religious temper is especially manifested in the invocations and elaborate similes which precede the catalogue of ships in the second book of the *Iliad*, and which seem to prove beyond doubt that the poem was handed down at first by oral tradition only.

In some countries, an oral transmission, even more faithful, has been achieved even with compositions in prose; but this has been the work of an organised and despotic hierarchy. The whole Vedic literature was thus preserved by a class of men who submitted to a discipline against which an Homeric rhapsodist would probably have rebelled. Eight-and-forty years were spent on the gigantic task of learning the Veda by heart; and the resolution of these devoted students was sustained by anathemas which warned them that 'they who sell the Vedas, and even they who write them, shall go to hell,' while their teachers impressed on them the fact that 'that knowledge of the truth is worth less which has been acquired from the Veda if the Veda has not been rightly comprehended, or if it has been learnt from writing.' (Max Müller, *History of Sanskrit Literature*, p. 502, &c.) But the whole interest of this Vedic literature was religious; and there is perhaps no reason for supposing that the unwritten history of any given period, or of successive generations, has been preserved for the main part unchanged, unless when it has been intrusted to the vehicle of a metrical form.

Hence, in the transmission of a large body of early Hellenic legends we may have a confidence which cannot be extended to those of Rome. Even in the former case, our confidence must be limited only to the transmission of the tale from the time when it was versified, and we are as far as ever from being able to extract the historical truth which may be contained in them. But in the Roman legends we cannot even ascertain how far the myths were tampered with or altered during the whole period which passed before the popular traditions were reduced to writing. The great beauty of many of these traditions has tempted historians like Niebuhr and Lord Macaulay to assume the existence of Roman epic poems, which were lost before the events in Roman history were recorded by contemporary historians. For the truth of this assumption there is, in the judgment of Sir G. Cornewall Lewis (*Credibility of Early Roman History*, ch. vi. sect. 5), not a shred of evidence. To assert that the myths of Romulus and the Tarquins, of Lucretia and Virginia, were embodied in epic poems, because they are full of passages of striking power, eloquence, and tenderness, is, in his opinion, to assume that the matter of a composition, and not its form, decides whether it is or is not a poem, and involves the conclusion that all poetical prose is poetry; while, further, of the original poetical form of these Roman legends no trace remains, unless we adopt the desperate hypothesis of Niebuhr, that the lex horrendi carminis, recited in the myth of the Curiatii, is a genuine fragment of the lost poem. On this Sir G. C. Lewis remarks, that the term *carmen* here denotes merely a legal formula, which is about as poetical as the schedules of the income-tax Acts.

Our confidence in the faithful transmission of these legends, as legends, must depend on the degree in which they escaped modification in the hands of writers who regarded themselves as historians. They would be preserved with tolerable fidelity only by those classes which had least literary culture; and how far this was the case with the old Roman stories, we are now unable to ascertain. But in Greece also a vast body of oral tradition not thrown into verse floated down along with the metrical compositions of the Homeric cycle. The distortion of these legends was in some measure arrested by the comparatively early introduction of writing into the Hellenic states; but although these tales were written down at a time long preceding the rise of anything like a literature in Rome, the multiplicity of versions in almost every incident in the legends is evidence enough of the influences which are constantly at work to modify all myths not handed down in a metrical form.

The conclusion seems to be, that unless a legend is embodied in a poem we have no guarantee whatever for its faithful transmission even as a legend; that if it be thrown into metre, we have in this circumstance a ground for believing that the story has remained substantially unchanged from the time when it was thrown into that form; but that even in the latter case we have no reason for attributing to any part of it a genuine historical character, unless we can corroborate it by statements of contemporary witnesses derived from other sources. For the Homeric ages such sources are confessedly wanting, while the annals of Rome exhibit the defects of oral tradition down to the time of the Punic wars. [ROLAND; ROMULUS; SEMIRAMIS; SERVIUS TULLIUS; SESOSTRIS; SIGURDR.]

TRADITION. In Theology, this term is commonly employed to denote any doctrine or alleged fact, delivered or handed down, and received on the faith that the first to whom it was delivered received it from an authentic source. Hence, it is used, generally, to denote that body of doctrine and discipline supposed to have been put forth in the first Christian age, and not committed to writing, the word being thus used in a contrary sense from *Scripture*. Such traditions are said to be of two sorts—*tradition of doctrine* (such as that of the Trinity), which is commonly said to be directly affirmed by tradition and proved by Scripture; and *tradition of rites and ceremonies*, called by Hooker 'traditions ecclesiastical,' or 'ordinances made in the prime of the Christian religion, established with that authority which Christ has left to His church in

matters indifferent, and, on that consideration, requisite to be observed till like authority give just cause to alter them.' (*Eccl. Pol.* v. 65.)

To the historian, traditions of alleged facts in the history of the Christian church will be subjects for precisely the same critical scrutiny which he applies to all other traditions, and for them as for others he will demand the evidence of contemporary written documents. Traditions of doctrine, in so far as they are matters of inference from written statements, lie out of the province of history; but in so far as they turn on alleged facts, those facts must be submitted to the ordinary tests of historical credibility.

Ecclesiastical tradition thus involves generally two questions: 1. Whether the given tradition is derived by inference from written statements in acknowledged books; and 2. Whether it be a genuine tradition from the time to which it is professedly ascribed. The former is a question chiefly of logic; the latter is strictly historical. Roman Catholic and Protestant theologians treat the subject, respectively, as follows.

The former hold tradition to be of equal authority with Scripture; but then they also hold that the church, i.e. the pope, with or without a council, is the authoritative declarer of tradition. At the council of Trent, the difficulty of determining who is to say what is tradition and what is not, struck the minds of the divines who were contending to fix the doctrine of the Catholic church. 'All agreed,' says Paolo Sarpi, 'that Christian faith is contained partly in Scripture and partly in tradition. Yea, some said more: that tradition was the only foundation of the Catholic doctrine; for the Scripture itself is not believed but by tradition.' But Vicenzo Lanello, a Franciscan friar, thought 'that they ought first to treat of the church, which is a more principal foundation;' since 'Scripture itself is founded upon it,' according to Saint Augustine's saying, and 'that no use can be made of traditions, except by grounding them upon the same authority.' But his opinion had no followers. 'Some objected that the synagogues of the heretics would also arrogate the authority of a church;' others thought that the authority of the church was sufficiently declared already. (Book ii.)

Protestants, on the other hand, without laying it down as a doctrine that tradition is equal to Scripture, have, in general, assented to the proposition that an authentic tradition of doctrine is binding; but to the question, What is the authority competent to pronounce a tradition authentic? they have given many answers, from a reluctance apparently to admit to its full extent that right of private judgment on which they founded their dissent from Rome.

When the early Reformers, especially those of the Lutheran and Anglican schools, attacked a doctrine or practice of Rome, their first endeavour was generally to show that it was not scriptural; their second, that it was not *ancient*, i.e. did not rest on tradition. For this purpose, they opposed to the authority of the church, as it existed in their day, the authority of early fathers and councils, as expounding the belief of an earlier age. Thus they *recognised* the right of private judgment to try the authority of the existing church by comparing it with authorities of earlier times; they permitted each individual to apply for himself the historical test. But at the same time they denied, more or less directly, the right of private judgment to go further, and criticise the ancient authority itself; to examine, for instance, whether a doctrine acquiesced in, in the fourth century, might not have been altogether unknown to the first; whether corruption in the church may not have commenced at so very early a period as to invalidate greatly the testimony even of the oldest father; and, lastly, whether traditions, resting on high historical authority, are or are not reasonable and credible. And even to the present day, the high church school of Anglican divinity practically considers all these as points without the reach of private judgment.

It would be impossible to refer to particular works on this subject of controversy. The extreme Protestant view of tradition is nowhere so fully argued as by Chillingworth, passim. For a concise view, on high church principles, of the estimate of tradition by the English Reformers, see Palmer's *Church of Christ*, vol. i. pp. 493, 504.

Trafalgar. In Printing, the name of a large type used in printing hand-bills or posting-bills. [TYPE.]

Tragacanth (Gr. τραγάκανθα). A variety of gum, the produce of the *Astragalus verus*, *creticus*, *gummifer*, and one or two other species. It is imported in small twisted or flattened pieces, white or yellowish in colour, and translucent or nearly opaque. When put into water they swell up and gradually form a gelatinous or pasty mass; not dissolving into a clear solution, as is the case with gum arabic. An analogous kind of gum is found in other plants, and the generic name of *tragacanthin* is sometimes applied to it.

Tragedy (Gr. τραγῳδία). A species of drama, in which the diction is elevated and the catastrophe melancholy. The name is usually derived from the ancient Greek custom of leading about a goat in procession at the festivals of Bacchus, in whose honour those choral odes were sung which were the groundwork of the Attic tragedy. Some recent writers, however, have given a new explanation of the word τράγος, considering it an ancient Greek adjective, and translating it *melancholy* or *lamentable*. [COMEDY; DRAMA; THEORIC FUND.]

Tragi-comedy. In Literature, a compound name, invented to express a class of dramatic compositions which should partake both of tragedy and comedy. If the mixture of serious with humorous portions in the piece alone entitles it to this name, then all the plays of Shakspeare (with the single exception of the *Merry Wives of Windsor*, to which some add

the *Twelfth Night*) belong to this class; as do, indeed, almost all the works of the old English dramatists. But *Troilus and Cressida* alone, of the plays of Shakspeare, bears this title in old editions. French critics define the distinction to be, that the *event* of the tragi-comedy is not unhappy or bloody.

Tragus (Gr. τράγος). In Anatomy, the term applied to the small cartilaginous eminence at the entrance of the external ear; in the adult it is beset with small hairs.

Trail (Span. traillar, akin to Lat. traho, *to draw*). In Artillery, that part of a gun carriage which, in travelling, is hooked up to the limber, but when the gun is unlimbered for action, rests on the ground, forming a third point of support, the wheels being the two other points. It usually stands at an angle of 21° with the ground.

Trailbaston, Justices of. In English Legal History, an itinerant court, appointed towards the end of the reign of Edward I., to inflict summary justice on disturbers of the peace, and occasionally afterwards. The most probable conjecture represents the name as a popular appellation, descriptive of the long staves which the marshals of the court carried or *trailed* after them. This kind of special commission fell into disuse in the reign of Richard II.

Trajectory (Lat. trajectus, *thrown beyond*). The curve which a body describes in space; e.g. the orbit of a planet or comet, or the path of a stone thrown obliquely upwards in the air. The form of the trajectory depends on the initial velocity with which the body is projected, the law and direction of the forces which act upon it, and the resistance of the medium in which it moves. The planetary orbits would be strictly elliptical were it not for the disturbing forces which they exert on each other; and but for the resistance of the air, a body projected obliquely from the earth would describe a portion of a parabolic curve.

In Geometry, the term *trajectory* is usually applied to a curve which cuts all curves of a given system at the same angle. When the angle in question is a right angle, the curve is said to be an *orthogonal trajectory*. Thus, a loxodromic curve on any surface is a trajectory of one of its systems of lines of curvature, whilst a line of curvature of the other system is an orthogonal trajectory of the first. In plane curves, again, a logarithmic spiral is a trajectory of a pencil of rays through its pole, whilst a circle around that pole as centre is an orthogonal trajectory of the pencil. The problem of finding the trajectories of a given system of curves requires the integral calculus for it solution. If $F(\xi, \eta, a)=0$, in which a is supposed to be a variable parameter, represent the system of curves, then $\frac{d\eta}{d\xi}=f(\xi, \eta, a)$ will be the tangent of the inclination of any curve to the abscissa axis at the point (ξ, η). Let $\frac{dy}{dx}$ have the same signification with respect to the trajectory at a point (x, y) coincident with (ξ, η), then c being the tangent of the constant angle, the condition

$$f(x, y, a)\frac{dy}{dx}=c\left[1+\frac{dy}{dx}f(x, y, a)\right]$$

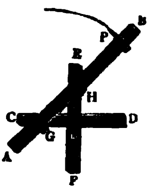
must be satisfied at the point where any trajectory cuts the curve individualised by a. Eliminating a by means of the relation $F(x, y, a)=0$, the differential equation of all the trajectories is obtained. For orthogonal trajectories the above condition reduces itself to $1+\frac{dy}{dx}f(x\,y\,a)=0$. Trajectories were first studied by John Bernoulli, and afterwards by James Bernoulli, Leibnitz, Sir I. Newton, Taylor, Euler, and others. Euler's three elaborate memoirs on the subject will be found in the *Novi Commen. Petrop.* vol. xiv. and *Nova Acta Petrop.* vol. i.

In a similar manner, a surface is said to be a trajectory of a given system of surfaces when it cuts the latter everywhere at the same angle. Orthogonal trajectories of this kind have been studied by Lagrange (*Berlin Memoirs*, 1779 and 1785), Euler (*Petersburg Memoirs*, vol. vii.), Dupin, and several others.

Trajectory. In Gunnery, the curved line described by the centre of gravity of a projectile in flight. [Gunnery; Projectile.]

Tram. [Silk.]

Trammel (Old Fr. tramel, the modern tramail). An instrument for drawing ovals, much in use among joiners and other artificers. It consists of a cross, C D E F, in which are cut two grooves at right angles to each other; and a beam, A B, carrying two pins, G, H (which are clamped to A B, and slide in their grooves), as well as a pencil, P: these parts are called the *cross* and the *beam*. By turning A B round, the pins G, H slide along the grooves, and the pencil P describes an elliptic curve. A demonstration of the properties of this instrument may be seen at p. 700, vol. xiv. of Hutton's *Abridgement of the Philosophical Transactions*.



Tramontane. [Ultramontane.]

Transcendental (Lat. transcendo, *I climb beyond*). In Algebra, a term applied to any quantity which cannot be represented by an algebraic expression of a finite number of terms with determinate indices. Such quantities include all exponential, logarithmic, and trigonometrical expressions. Thus a^x, $\log x$, $\tan x$, &c. are transcendental quantities; and any equation into which such quantities enter is called a *transcendental equation*, and any curve defined by such an equation is called a *transcendental curve*.

Transcendental. In Anatomy, the term has been applied to that branch which treats of the essential nature and homologies of the parts of the body, and the results of which

study seem to be different from, or beyond, what would be suggested by the ideas of the parts derived from the outward senses; as when the human blade-bone, which to the eye is very different from a human rib, and which is quite distinct from the skull, is seen by the mind to be the rib of the occiput.

Transcendental. A word used by German philosophers to express that which *transcends* or *goes beyond* the limits of actual experience. This general meaning is somewhat restricted by Kant, who draws a distinction between the *transcendental* and the *transcendent*. The transcendental he defines to be that which, though it could never be derived from experience, yet is necessarily connected with experience, and which may be shortly expressed as the intellectual *form*, the *matter* of which is supplied by sense. 'I call,' says he, 'all knowledge transcendental, which has regard in general not so much to *objects* as to our mode of knowing or apprehending objects (i.e. to formal knowledge), so far as this is conceived to be possible à priori. A system of such conceptions would be named transcendental philosophy, as the system of all the principles of pure reason.' The *transcendent*, on the contrary, is that which regards those principles as objectively real to which Kant assigns only a subjective or formal reality, and consequently is by him regarded as beyond the limits of the human reason altogether.

Transept (Lat. trans, and septum, *a place enclosed*). In Architecture, that portion of a church or other building which extends on the north and south sides of the area between the nave and the choir, and forming the short arms of the cross upon which the plan of cruciform churches is laid out.

Transfiguration (Lat. transfiguratio). This word is applied especially to the event recorded in Matt. xvii., Mark ix., Luke ix., where it is related that Christ took Peter, James, and John up into a high mountain, and was transfigured before them, His face shining as the sun, and His raiment glistering, while there appeared in conversation with Him, Moses and Elias. An ancient tradition assigns Mount Tabor as the scene of this event, upon which three contiguous grottoes have been fashioned to represent the three tabernacles which Peter desired to raise upon the mount.

Transformation (Lat. transformatio). In Algebra, transformation consists in replacing the variables or facients of a given expression by functions of another set of variables. When these functions are of the first degree in the new variables, the transformation is said to be *linear*. [Linear Transformations.] The *transformation of co-ordinates*, in Geometry, is a case of linear transformation. [Co-ordinates, Transformation of.]

Transformation, Tschirnhausen's. [Tschirnhausen's Transformation.]

Transfusion (Lat. transfusio, from fundo, *I pour*). The injection of blood from one living animal into another. It was at one time supposed that this operation might be resorted to, to sustain life in cases of great loss of blood from accidental hæmorrhages and other causes, and that in certain cases of mental and bodily disease a cure might be effected by abstracting a large quantity of blood, and supplying its place by transfusion from another person, or from an animal, such as a calf or sheep. Some of these experiments appeared at first to be attended with success, but bad consequences followed; and in two or three cases in which it was tried upon the human subject it proved fatal. Much was hoped from this practice, but it has now quite fallen into disuse.

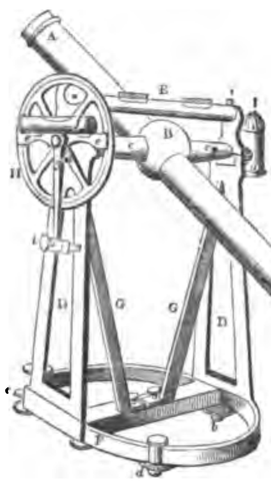
Transit (Lat. transitus, *passage*). In Astronomy, the culmination or passage of a celestial object across the meridian of any place. The determination of the exact times of such transits is one of the most important operations of practical astronomy, as it is by this means that the differences of right ascensions, and consequently the relative situations of the fixed stars, and the motions of the planets and comets in respect of the celestial meridians, become known; and it is most easily and accurately effected by the aid of the Transit Instrument, the nature and method of using which will be explained under that term.

Transit is also used to signify the passage of an inferior planet across the sun's disc. [Mercury; Venus.]

Transit Circle. [Transit Instrument.]

Transit Instrument, Transit Circle. The transit instrument, called by the French *instrument des passages, lunette méridienne*, consists essentially of a telescope firmly attached to a transverse horizontal axis, the ends of which are directed to the east and west points of the horizon. It is used primarily to note the *time* of passage of a celestial object across the meridian. In the *transit circle* we have a large circle added to the instrument, for the purpose of noting primarily the *altitude of the star* with the greatest accuracy as well as the time of its passage. The extremities of the axis of the telescope common to both instruments are formed into cylindrical pivots of exactly equal diameters, which rest in notches (technically called Y's, from their resemblance to that letter), formed in metallic supports, susceptible of nice adjustment both horizontally and vertically, so that the axis can be placed perfectly horizontal, and at right angles to the plane of the meridian in which the telescope moves. In the focus of the eye-piece is placed a system of three, five, or sometimes seven vertical and equidistant wires or spider-lines, generally crossed by two horizontal ones, between which it is convenient that the passage of objects over the central wires should be observed. By means of adjusting screws the diaphragm, or plate to which the wires are attached, is brought into such a position that the middle vertical wire intersects the optical axis of the telescope, in which position it is permanently fixed.

When the system of wires is brought into this position, the middle one will be a visible representation of that part of the meridian to which the telescope is directed; and when a star is seen to pass this wire, it is in the act of culminating, or *transiting* the celestial meridian. The instant of the transit is noted on a clock or chronometer, which is an indispensable accompaniment of the instrument; and in order to render the observation more certain, the instant at which the star passes each of the vertical wires is noted, when practicable, and the mean taken as the true instant of passing the central wire. The sidereal times at which certain principal stars pass the meridian of Greenwich (and consequently the meridian of any other place whose longitude from Greenwich is known) being given in the *Nautical Almanac*, the comparison of the time indicated by the clock and the time in the almanac gives the *clock error*; and by observing the same stars from day to day the *clock rate* is determined. In this



manner we are enabled to assign the exact interval of sidereal time between the transits of the different stars, and consequently the difference of the right ascensions.

The annexed diagram represents the *portable* transit instrument, as at present constructed by Troughton and Simms, when the telescope does not exceed twenty inches or two feet in focal length. The telescope tube AA is in two parts, connected together by a sphere B, which also receives the larger ends of the two cones *cc* placed at right angles to the telescope, and forming the horizontal axis. The axis terminates in two cylindrical pivots, which rest in Y's fixed at the top of the vertical standards DD. One of the Y's has a small motion in azimuth, by means of which the telescope can be adjusted to the plane of the meridian. A spirit level E, which is made to stride across the telescope and rest on the two pivots, serves to show when the axis is horizontal. The standards D D are fixed by screws upon a brass circle F, which rests on three screws, *b*, *c*, *d*, forming the feet of the instrument, and by which the levelling is performed. G G are two oblique braces for the purpose of steadying the supports. On the extremity of one of the pivots, which extends beyond its Y, is fixed a divided circle H, which turns with the axis; while a double vernier remains stationary in a horizontal position, and shows the altitude to which the telescope is elevated. The verniers are set horizontal by means of a spirit level *f*, and are fixed in their position by a brass arm *g h*, clamped to the supports. The whole of this apparatus is movable with the telescope, and when the axis is reversed can be attached in the same manner to the opposite standard. For the purpose of illuminating the wires when observations are made at night, one of the pivots is pierced, and admits the light of a lamp I, which is thrown upon the wires by a reflector placed diagonally in the sphere B. (Simms's *Treatise on Mathematical Instruments*.)

Several improvements, both in application and in construction, have recently been made in this important instrument. The principal new application is that by which it is made to determine the latitude of the place of observation, or the zenith distances of stars, by being placed at right angles to its ordinary position, i. e. with its line of collimation lying in the plane of its prime vertical. A large instrument of this class, called a *prime vertical instrument*, recently erected at the observatory of Pulkowa, serves to determine with admirable precision the zenith distances of stars which pass near the zenith of that observatory; and M. Struve considers its use to be of extreme importance in the ulterior investigations connected with aberration, precession, and nutation.

Mr. Simms produced at the Great Exhibition of 1851, a specimen of a *double-transit instrument*, i. e. an instrument which might be used with equal facility when placed in the meridian and in the prime vertical. This is effected by making the axis of the telescope itself convertible into a telescope by having an object-glass fitted into one of the pivots, and a sliding tube carrying an adjustible cross of delicate spider-lines with a positive eye-piece at the other pivot. The adjustment of the axis telescope is effected by a small collimator placed in a line with the axis. The axis is turned round, and the position of the wire-frame is shifted till the centre wire coincides with the mark equally well before and after reversion. If the meridian telescope be previously adjusted, it can be made use of for readily placing the axis telescope in its proper position for the determination of latitude by means of the transits of stars which pass the meridian near the zenith.

Another kind of transit instrument lately brought into use is the *diagonal* or *chamber transit*. The peculiarity of this instrument is, that the rays tending to form an image of a star, after passing through the object-glass, do not proceed in a straight line through the tube in the usual way, but, being received upon a speculum or prism placed in the axis, are turned aside through one of the axes, which is perforated and provided with an eye-piece and a system of wires. The inconvenience of placing the body in awkward positions for the observations of stars, so much felt in the use of small transits, is thus avoided, and the observer has no need to shift his position, whatever be the altitude of the star to be observed. Mr. Simms has succeeded in providing convenient means for the illumination of the field of view of the diagonal transit by the following method: The back pivot being also perforated has a small convex lens set within it, and a larger convex lens is fixed within the axis at the back of the reflector, of such a size that one or more segments near the edges project beyond the edge of the reflector. The light of a lamp placed outside the pivot is condensed by the small lens, and the rays after crossing diverge upon the large lens at the back of the reflector, the outer segments of which again condense it upon the field of view in sufficient quantity to produce a well-illuminated field.

Another improvement is the *prism illumination* of the field of view of transit instruments. It has always been a difficult problem for practical astronomers to provide for the observation of very faint objects, for which it is necessary to have the field of view dark and the wires illuminated. Various means, attended with only partial success, have been devised in different observatories, the most successful of which was till recently the application of the galvanic current. Mr. Airy applied for the first time the *prism-illumination* to the great transit circle at Greenwich, in the year 1850; and this method, which is equally remarkable for its simplicity and facility of application, is now applied to small instruments, and will probably supersede all other methods. A pierced reflector is placed as usual in the central part of the axis of the telescope; but this, instead of being fixed, has a motion round an axis, so that it can be placed at any angle of inclination to the tube, being acted on by means of a rod projecting through the eye end of the telescope tube near the observer's hand. If the rod be pulled out to its full length, the reflector stands at its usual angle of 45°, and the field is *fully illuminated* by the lamp placed at the axis. By pushing the rod, the reflector is made to stand more nearly at right angles to the tube; and the light, being thrown down the tube in smaller quantity, is thus *moderated*. Finally, when the reflector is at right angles to the tube, no light passes down it to the eye, but in this case the prism application comes into play. Four right-angled glass prisms are placed symmetrically round the ring of the reflector, one of the sides of each receiving the rays from the axis lamp perpendicularly. The light reflected from their hypothenusal sides, and passing perpendicularly through their remaining sides, is made to proceed parallel to the sides of the tube. It is then finally received upon four other prisms placed properly in the plane of the wires of the telescope, so as to be transmitted entirely in that plane, and to illuminate perfectly both sides of the vertical wires, and the upper and under sides of the horizontal wires. This process has been for some time used with perfect success for the illumination of the wires of the transit circle at Greenwich.

Adjustments.—In practice, the transit instrument is subject to three principal errors. 1st. The optical axis of the telescope may not be quite perpendicular to the axis of the instrument; which is called the *error of collimation.* 2nd. The axis may not be perfectly horizontal; which is called the *error of level.* And 3rd. The axis may not be exactly east and west, or the optical axis may not be exactly in the meridian; which is called the *error of azimuth.* The error of collimation is detected by pointing the telescope to a distant well-defined terrestrial object, and bisecting it by the middle vertical wire; the telescope is then lifted out of its supports and reversed (i.e. the end of the axis which was turned to the west is now turned to the east), and brought again to bear on the same object. If the middle wire is found to be still bisected, the adjustment is perfect; if not, the diaphragm is moved a little to the right or left by means of the adjusting screws, until the middle wire bisects the object in both positions of the axis. To place the axis exactly horizontal, the level E is suspended in the proper manner from the pivots, and the air bubble brought to the middle by means of the foot screws. The level is then reversed, i.e. the end which was turned to the west is now turned to the east; and if the air bubble still stands at the middle, the axis is horizontal; if not, the foot screws are adjusted until it stands at the middle in both positions of the level. To place the instrument exactly in the meridian, some knowledge of practical astronomy is required. It is easy to place it *nearly* in the meridian by the transit of the sun at apparent noon, or of any star whose right ascension is known; and when in this approximate position to the meridian, the deviation may be discovered and corrected in various ways. One of the simplest is to observe two successive transits of Polaris (or any circumpolar star) above and below the pole. If the interval between the two transits is exactly twelve sidereal hours, the telescope is exactly in the meridian; and the difference of the interval from twelve hours shows both the amount and the direction of the azimuthal error. A similar process may be used with a high star and a low star for showing whether the instrument deviates much in

azimuth, by comparing the difference of their imes of transit with the difference of their right ascensions. In the case of fixed instruments, a meridian mark is usually made on some distant object, and permanently established for the convenience of ready reference.

The transit instrument appears to have been invented by the Danish astronomer Roemer, by whom it was first described in 1700, in the *Miscellanea Berolinensia*, tome iii. Dr. Halley placed a transit instrument in the Greenwich Observatory in 1721, the telescope of which was about five feet in length; but it was little used until 1742, when Bradley commenced a regular series of meridional observations. The transit instrument till lately in use in the Royal Observatory is the workmanship of Troughton, and was set up in 1816. It has recently been superseded by the gigantic transit circle now in use.

The finest example of the *transit circle* is the meridian instrument erected at Greenwich, by the astronomer royal, Mr. Airy, in 1850; and, from the beginning of 1851, all the meridian observations have been made with it. It consists mainly of a telescope of 12 feet focal length, with an object-glass of 8 inches clear aperture, carrying on each side of its centre a circle of 6 feet diameter. The tube of the telescope is of iron cast in four pieces, viz. two immense cones at its eye end and object end, and a large central cube in two pieces, having attached to them in the same casts the pivots on which the telescope revolves. The cones weigh each about 1¾ cwt. and the central cube with its pivots weighs nearly 8 cwt. The two parts of the cube are bolted together on flanges with planed surfaces, as also are the cones to the central cube. The surfaces of the pivots were hardened after the casting, by chilling them to a depth of about a quarter of an inch, and were afterwards ground and polished to a true cylindrical form after a great expenditure of time and labour. The circles are carried on cylindrical rims on the east and west sides of the central cube. The western circle has a *dished* surface of about 3 inches in breadth with its concavity westward, and carries two bands, one on its eastern and one on its western surface, the latter being divided to 5′ of space. The eastern divisions are merely given for the convenience of setting the instrument accurately to given objects by means of a pointer; but the western divisions are for the observations of zenith distance. For the reading of the circle, six long microscopes are fixed in the solid stone of the western pier, having their object-glasses arranged in a circle of about 5½ feet diameter on the inner or eastern surface, and their eyepieces in a circle of about 2 feet in diameter at the back of the piers. The centres of these circles are in the same horizontal line with the centre of the telescope, and at the height of 5 feet from the floor. The microscopes, whose axes lie in a conical surface, are each 45 inches in length, and their axes are not quite perpendicular to the portions of the surface of the circle opposite to them, but are inclined in such a way that the light thrown through corresponding illuminating holes (cut in the pier) from a central gas lamp shall be reflected truly into them without the aid of specula. The error of collimation of the telescope is found by means of two 5-ft. telescopes, called *collimators*, one to the north and the other to the south of it, and the error of level is found by the observation of the reflected image of the central wire by means of Bohnenberger's eye-piece; by which means also, together with observations of stars by reflection, the zenith point is found. An apparatus is provided by which the instrument can be lifted at pleasure out of its Y's so as to be in the same state of strain when elevated as when resting in its Y's. This arrangement was considered necessary to enable observations of collimator by collimator to be made. This is now done by means of holes which have been pierced in the two corresponding sides of the cube. The apparatus for carrying the mercury trough, which usually contains about 60 lbs. of mercury, is ingenious, and motions are readily given to it either in a north and south, or in an east and west, direction.

For illumination of the wires with a dark field, eight prisms are employed. Four of these are arranged symmetrically on the reflector, which is placed at the centre of the telescope as usual, but which is movable round an axis, and can be acted upon by a rod passing through the tube of the telescope and having its end near the eye-piece; and four are arranged symmetrically in the plane of the wires in the eye-piece. By this means, when the field is dark or the reflector is at right angles to the tube, the light after reflexion by the two sets of prisms is thrown across the field in the plane of the wires, and illuminates them abundantly for observation.

The casting and the engineering generally for this instrument were conducted by Messrs. Ransomes and May of Ipswich; but the dividing of the circles, and all the optical part of it, were performed by Mr. Simms. The object-glass is also of his manufacture.

Messrs. Cooke and Sons have recently constructed a transit instrument for the Indian Trigonometrical Survey, in which they have introduced several new principles of great ingenuity and importance. Four swing levels are attached to the cube, by means of which reversals are rendered unnecessary. The means of adjustment, and the finish and detail of the parts, leave nothing to be desired.

Transition (Lat. transitio, *a passing over*). A term formerly used in Geology to designate a series of rocks now referred to the Palæozoic period. They were long regarded as representing a state of transition from the apparently unformed condition which the older rocks were believed to exhibit, to the more complete state of rocks of a newer period. The term is now rarely used in English works, though still met

with occasionally in foreign geological treatises, chiefly French.

Transitive Verbs. [VERBS.]

Transitory Actions. In English Law, actions in which the *venue*, i.e. place alleged in the declaration, is immaterial, and consequently the trial may be had in any county; opposed to *local actions*, in which the trial can only be had in the county where the alleged injury was committed. To the former class belong most personal actions. [ACTION; VENUE.]

Transitu, In (Lat. *in the act of passage*). In Law, goods are said to be liable to *stoppage in transitu* when detained by one having a right to do so in their way to their destination; as, by an unpaid vendor, in case of the vendee's insolvency. In international law, it is held that the property of parties belligerent cannot change its national character during the voyage from port to port, i.e. *in transitu*.

Translation. In Law, the removal of a bishop from one see to another.

Translation, Motion of. In Mechanics, the motion in virtue of which the several particles of a body describe equal and parallel right lines.

Translucency (Lat. transluceo, *I shine through*). Semitransparency. The term is chiefly used in Descriptive Mineralogy as applied to minerals which admit of a passage of the rays of light, but through which objects cannot be definitely distinguished.

Transmigration of Souls. [METEMPSYCHOSIS; PYTHAGOREAN.]

Transmutation (Lat. transmutatio, from muto, *I change*). In ALCHEMY, the pretended operation of changing the imperfect metals (as they were termed) into the two precious metals, gold and silver.

TRANSMUTATION. In Geometry, the change of one figure or body into another of equal area or solidity; as a triangle into an equivalent square, a sphere into a cube, &c.

Transom (Lat. transenna). In Architecture, the horizontal piece framed across a double-light window: when a window has no transom, it is called a *clere-story* window.

Transoms. In Shipbuilding, beams bolted across the sternpost, to receive the after ends of the several decks, and to give form to the stern.

Transparency. That quality in certain bodies by which they give passage to the rays of light. It is generally supposed to be a consequence of the homogeneity of the matter of which they are composed.

Transpiration (Lat. trans, and spiro, *I breathe*). Gases exhibit peculiar properties in passing through tubes of very small diameter. The rates at which they flow through such tubes vary with the composition of the gas, but bear a constant relation not coinciding with density, diffusion, or any other known property. These fundamental peculiarities are termed by Graham those of transpiration. The experiments by which they were established were analogous to those of Poiseuille and Regnault on the efflux of liquids through tubes of great length in comparison with diameter. The transpiration of a gas is uninfluenced by the material of which a tube is constructed; it increases with pressure—the greater the density, the shorter the time of transpiration; it is inversely proportionate to the length of the tube; slower at low than at high temperatures. Oxygen has the slowest rate of transpiration, and may be taken as the unit for purposes of comparison, $=1$; chlorine is 1·5; hydrogen 2·288. Graham considers that transpiration is probably the resultant of a kind of elasticity depending on the absolute quantity of heat, latent as well as sensible, which different gases contain under the same volume.

Transplanting (Lat. transplanto, *to transplant*). The art of removing a plant or tree from one situation to another in such a manner that it may continue to grow. The operation is commonly performed in the winter season, or in autumn and spring, when plants are generally in a dormant state; and the great object of the transplanter is to lift as many of the roots as possible without injuring them, and to replace them in a new situation to which the tree is transplanted in such a manner as to facilitate their growth. With herbaceous plants and young trees this is comparatively a simple operation; but with large trees it is an operation of skill, care, and labour.

When a large tree is to be transplanted, it should be considerably under the normal age of the species; and to prepare it for the change which it is to undergo, other trees, or objects of its own height with which it is surrounded, should be taken away a year or two previous to removal, in order to accustom it to the direct action of the light and air on every portion which is above ground. The next part of the operation is to dig a trench round the tree equidistant from the trunk, at the distance of three, six, nine, or twelve feet, according to its height, and to such a depth as to cut through all the horizontal roots. The tree may then be removed to its new situation, with or without the earth attached to that part of the roots which remain; or (which is a more certain mode) the trench may be left open during a year, in order that the sections of the amputated roots may heal over, and be prepared to emit new fibrous roots after the tree is transplanted; or (which is the more general mode) the trench may be filled up with finely pulverised soil, in order to encourage the production of fibrous roots; and at the end of a year, or of two years if the tree is very large, it may be removed to its final situation. The earth should be filled in carefully and made firm about the roots, which should be spread horizontally in all directions. In a moist climate, the branches may all be retained; but in dry climates, it may be desirable to thin them out moderately; this pruning should, however, never be carried to excess.

The proper season for transplanting all ligneous deciduous plants, whether small or

large, is early in autumn, after the leaves have dropped. In the cases of kitchen garden plants and others of herbaceous habit, where it is done at any season, transplanting is most successful if carried out in showery weather. Evergreen trees may also be transplanted in the autumn, but with equal success in early summer after growth has commenced.

As a general rule, it may be stated, that the less damage sustained by the smaller roots and their fibrils, the more successful will be the operation. The chief further precaution is to check excessive evaporation from the leaves, so that their healthy action may be maintained.

Transport (Lat. trans, and porto, *I carry*). A vessel employed by government to convey stores, troops, &c.

Transportation (Lat. transportatio, *a carrying across*). In Law, a species of punishment. It is not known to the common law of England, and was originally a commutation of punishment, pardon being granted to offenders of various kinds on condition of undergoing transportation: generally for seven or fourteen years, or for life. It was till lately a statutable punishment for a great variety of offences. It is said to have been first inflicted as a punishment by 39 Eliz. c. 4, enacting that such rogues as were dangerous to the inferior people should be banished. At that time the English plantations in North America were the receptacles of transported convicts. Virginia, the Jerseys, Delaware, Maryland, &c. are the districts which received the greatest accession to their population in this way. At the very commencement of the practice, the same arguments were employed against it by Lord Bacon which are urged at this day by many law reformers. 'It is,' he says, 'a shameful and unblessed thing to take the scum of people, and wicked condemned men, to be those with whom you plant.' It was not, however, brought into general use as a punishment until 1718, by 4 Geo. I., which Act gave the courts a discretionary power to banish to the American plantations felons entitled to benefit of clergy. After the loss of the greater part of our American colonies, several years elapsed before the government fixed on any place by way of substitute. At length, in 1787, Botany Bay, on the coast of New South Wales, was fixed upon: 760 convicts were despatched that year. But when the expedition arrived, it appeared that Botany Bay (discovered by Cook in 1770) afforded no practicable site for the colony; which was consequently landed at Port Jackson, where the town of Sydney was founded.

In a few years afterwards, convicts were also transported to Van Diemen's Land (now Tasmania), and these two colonies continued for a long period to be the only, and were always the principal, recipients of our convicts. Two committees sat on the subject of transportation in 1838 and 1839, and from the publication of their reports an unfavourable view of the punishments which had hitherto been popular with the governing classes in England originated. Convicts at that time were disposed of either by *assignment*, under a kind of compulsory servitude to masters; in the service of government; in the road and chain gangs; in the penal settlements; in chain gangs in the penal settlements. The evidence taken before the committee in question led many to believe that while *assignment* was ineffective, by reason of its uncertainty and general absence of restraint, the *penal settlements* (Norfolk Island in particular) were replete with evil from the demoralisation engendered by them. Various schemes were consequently suggested, and partially tried, for amendment of the system, such as *tickets of leave*, which entitled the criminal to work for whom and where he pleased, provided he remained within the limits of his sentence; *exile*, under which a convict underwent part of his punishment at home, and the remainder under favourable conditions in a penal colony; *conditional pardons*, under which the convict became free for all purposes except that of returning to England. But of these and other devices little can be said, because they were never fully tried, the conflict between the Australian colonies and the mother country between 1850 and 1854 on the subject of transportation having ended in its abolition in 1857 (20 & 21 Vict. c. 3. s. 2), and the substitution of PENAL SERVITUDE. The sentence of penal servitude itself, may, however, be carried out (as regards males) by employment on public works out of the country, the present establishments for which purpose are at Bermuda and Gibraltar.

Although the subject has ceased for the present to be of practical importance in this country, yet it is impossible to say how soon the pressure on society occasioned by the secondary punishments now substituted for it may not cause it to be resorted to again.

As compared with the best regulated systems of imprisonment: 1. In respect of its effects on the convict himself; it may be doubted whether in the Penitentiary, on either the silent or the separate system, the mind of the majority of sufferers goes through a more wholesome process than in the penal settlements, notwithstanding all that we have heard even of the frightful condition of Norfolk Island, which was not an ordinary sample. 2. In respect of its effects on the ill-disposed population at home; the experience of anyone conversant with courts of justice will decide which sentence appears to produce the greatest impression when announced—imprisonment or banishment. And it must not be forgotten that it is not the real severity, but the action on the imagination, which deters from crime: the worst inflictions of the gaol are thought little of by anyone except the sufferer, while the evils of expatriation are greater in idea than in reality. 3. In respect of the ultimate reform of the offender; transportation pos-

sesses an incalculable advantage over every other secondary punishment. The convict who has undergone it begins life afresh: he remains, indeed, under some disabilities, sufficient to mark the sense entertained by society of the difference between him and the man unstained by crime; but there is nothing to prevent his rising by regular and honest conduct, if he chooses, into a station of comfort, and even of respectability. The man who leaves a gaol is utterly ruined. Society has devised, and perhaps can devise, no means of extending to him a jus postliminii, and bringing him back within the pale of citizenship.

Transposition (Lat. transpositus, part. of transpono, *I change the place*). In Algebra, the transposing of a term from one side of an equation to the other. It is in effect the adding of equal quantities to or subtracting equal quantities from each side of the equation, the *sign* of the quantity being changed from + to −, or from − to +. For example, if $a+x=c-d$, by transposing a we have $x=c-d-a$; or if $a+b=c-x$, by transposing x and $a+b$ we get $x=c-a-b$. The object of transposition generally is to bring all the unknown terms to one side of the equation for more conveniently finding their value with respect to the known terms.

TRANSPOSITION. In Music, the change which takes place by performing the same melody in a higher or lower key.

Transubstantiation (Lat. trans, and substantia, *substance*). The doctrine held by the church of Rome, that in the Eucharist the bread and wine are annihilated and replaced by the body and blood of Christ. In one of its liturgical offices its says, 'This *is not bread*, but God and Man, my Saviour.' By the opponents of the church of Rome it is maintained that this dogma is not found in Scripture, or in the writings of the fathers, or in the canons of the early church.

Transudation (Lat. trans, and sudo, *I transpire*). The oozing of fluids through membranes, or through porous bodies. The process is carried on by means either of ENDOSMOSIS or of EXOSMOSIS.

Transversal (Lat. transversus). In Geometry, the name given to a line (whether straight or curved) which *traverses* or intersects any system of other lines; as when a straight line intersects the three sides of a triangle. The properties of straight and circular transversals are discussed by Carnot, in his *Géométrie de Position*, and *Essai sur la Théorie des Transversales*.

In the former of these works, Carnot establishes the following general theorem, which, on account of its numerous applications, deserves enunciation. Let a_1, a_2, &c. . . . a_n be the points in which the side opposite the angle A of a triangle ABC is cut by a transversal curve of the n^{th} order; b_1, b_2, . . b_n the points in which the same curve cuts the side opposite B; and c_1, c_2, . . . c_n the points in which it cuts the side opposite C, then—

$$\frac{a_1B}{a_1C}\cdot\frac{a_2B}{a_2C}\cdots\frac{a_nB}{a_nC}\cdot\frac{b_1C}{b_1A}\cdot\frac{b_2C}{b_2A}\cdots\frac{b_nC}{b_nA}\cdot\frac{c_1A}{c_1B}\cdot\frac{c_2A}{c_2B}\cdots\frac{c_nA}{c_nB}=1,$$

provided a segment such as $m\,n$ be considered as positive or negative, accordingly as the direction from m to n coincides or not with that in which the perimeter of the triangle is conceived to be described. Carnot's theorem is, in reality, more general than the above, having been extended by him to any polygon whatever. When the transversal is a right line, Carnot's theorem gives the well-known one of Menelaus—

$$\frac{a_1B}{a_1C}\cdot\frac{b_1C}{b_1A}\cdot\frac{c_1A}{c_1B}=1,$$

the converse of which is also true. The correlative theorem and its converse is ascribed to the Italian Ceva: viz. If transversals be drawn from the angles of a triangle through the same point of the plane so as to cut the opposite sides in a, b, c, then—

$$\frac{a\,B}{a\,C}\cdot\frac{b\,C}{b\,A}\cdot\frac{c\,A}{c\,B}=-1.$$

Upon these two theorems Chasles bases his two systems of point, and line co-ordinates. (*Géométrie Supérieure*.) As a further illustration of the power of Carnot's theorem, which is itself founded on one of Newton's (*Enumeratio Linearum Tertii Ordinis*), suppose the transversal to be a cubic and the triangle to be formed by its three stationary tangents, whose corresponding points of inflexion are at a_1, b_1, c_1, respectively, then—

$$\frac{a_1B^3}{a_1C^3}\cdot\frac{b_1C^3}{b_1A^3}\cdot\frac{c_1A^3}{c_1B^3}=1;$$

so that, taking the cube root of both sides, we learn that the three points of inflexion of every cubic must lie in a right line. Or, again, let a transversal cut a cubic in a, b, c, and let ABC be the triangle formed by the tangents at the points of intersection; then BC will meet the cubic again in a point a_1, the tangential of a; CA will meet it in b_1, the tangential of b; and AB in c_1, the tangential of c [TANGENTIAL], in such a manner that—

$$\frac{aB^2}{aC^2}\cdot\frac{a_1B}{a_1C}\cdot\frac{bC^2}{bA^2}\cdot\frac{b_1C}{b_1A}\cdot\frac{cA^2}{cB^2}\cdot\frac{c_1A}{c_1B}=1;$$

but by hypothesis the product of the squared fifth ratios is unity, hence also that of the others must be so, and the three tangentials must lie in a right line.

Transverse Axis. In Conic Sections, the diameter which passes through both foci. It is the longest diameter in the ellipse, the shortest in the hyperbola; and in the parabola it and all the other diameters are infinite. [CONIC SECTIONS.]

Trap-rock. When Geology was first studied, a number of rocks were found to be similar in general appearance and composition, while all were remarkable for being spread out in

tabular or flat masses, one such flat mass extending beyond another, so that there was a rough resemblance to stairs. These rocks were hence called by a Swedish author *trappa*, the Swedish word for steps or stairs, and the name *trap* has ever since been received in reference to these. They have lông been recognised as belonging to the class seen in volcanic countries, and generally called *lava*, being, in fact, the melted material poured out from an active volcano in the state of a thick paste, and spreading itself over the surface adjacent. A succession of eruptions produces a series of steps; and where no volcano now exists, the old erupted lavas often remain. Of the various tabular erupted rocks thus named, *basalt* is the most distinctly an ancient lava, and is the most important. *Greenstone, whinstone, toadstone* (todtstein), and others, are names of varieties of basalt, and are also trap-rocks. [BASALT.]

The following may be selected as illustrative instances of the aspects, characters, and situations of trap-rock: Under the name of *greenstone* it is seen in characteristic masses, associated with the granite, mica-slate, and serpentine of the Lizard Point in Cornwall. Near Kington and Radnor in Wales, it accompanies clay-slate and old red sandstone; and upon the northern side of Snowdon, Plynlimmon, and Cader Idris, coarse-grained, and with regular crystals of hornblende in one place, and in another fine-grained, homogeneous, and even basaltic or columnar. In Derbyshire, under the name of *toadstone*, this rock is associated with mountain limestone, and with new red sandstone or red marl in the coalfields of the north of England and elsewhere. In Antrim we find it variously blended with the sandstone and chalk, and even sometimes superior to the newest secondary formations. These instances will serve to show the varied position of these rocks. In regard to their aspects, we observe them in Cornwall forming blocks and masses, not unlike the granite of the country. Sometimes, as in the coalfields, they form immense walls or dikes, and even axes of elevation; sometimes, as in Derbyshire, they have the appearance of stratification. In the Isle of Mull and elsewhere, they are massive and amorphous, and in many places columnar. The coast of Antrim, the island of Staffa, and some parts of Mull furnish magnificent instances. The Isle of Mull, Ulva, and the Tresharnish Isles exhibit trap rocks and veins in the greatest variety; and the veins of the Isle of Skye are remarkable not only for their singular extent and arrangement, but for the changes effected by them upon the rocks which they penetrate, and which are of such a nature as to throw some light upon the chemical phenomena connected with geology. Two of these veins penetrate the white marble of Strath. At their junction, the trap passes into a substance resembling serpentine, and is penetrated by fissures containing steatite; while the marble acquires all sorts of colours, and changes in composition from argillaceous to magnesian, and from magnesian to silicious. In other parts, the trap veins exhibit the several varieties of greenstone, basalt, and amygdaloid.

Very much more extensive and important masses of trap-rock are to be found in India, where the most singular results are produced by subsequent partial breaking-up by water action. Something of the same kind, but on a smaller scale, is exhibited in the Auvergne country in Central France.

Trap-tree. A species of *Artocarpus*, which furnishes a gutta or glutinous gum, used as birdlime in Singapore.

Trapa (abridged from Mod. Lat. calcitrapa, *caltrops*). A genus of *Haloragaceæ*, consisting of floating plants, chiefly natives of India, China, and Japan. The singular four-horned fruits of the European species, *Trapa natans*, which was the only one formerly known, have been compared to the spiked iron instruments called *caltrops*, employed in ancient warfare for strewing on the ground to impede the progress of cavalry; and, as growing in water, the plant is commonly called the *Water Caltrops*. The seeds of all these plants abound in starch, and are much eaten as food. Those of *T. natans* —called *Jesuits' nuts* at Venice, and *Chataigne d'Eau* by the French—are ground into flour and made into bread in some parts of Southern Europe. In Cashmere those of *T. bispinosa*, the Sinhara of the natives, feed 30,000 persons for five months in the year, and are so extensively collected that the celebrated Runjeet Singh of Lahore derived a revenue of 12,000*l.* per annum from them. *T. bicornis*, the Ling of the Chinese, has a fruit like a bull's head, and its seeds are also a considerable article of food.

Trapezium (Gr. τραπέζιον, *a small table*). In Histology, a small transverse band of fibres, which has been discovered in the brain of most mammalia and in the apes, behind the pons, at the origin of the seventh and eighth pairs of nerves. It was considered to be absent in man, but its presence has been recently demonstrated by Lockhart Clarke.

Trapezium and Trapezoid. In Geometry, an ordinary quadrilateral figure is sometimes called a *trapezium*; when two of its sides are parallel without being equal, it is called a *trapezoid*. The following properties of a trapezium may be mentioned: 1. The sum of the squares on the sides is equal to the sum of the squares on the diagonals, together with four times the square on the line joining the middle points of the diagonals. 2. This line joining the middle points of the diagonals is bisected by, and bisects the line joining the middle points of any two opposite sides. Hence it follows that the lines joining, in order, the middle points of the sides form a parallelogram. 3. The centre of gravity of the *surface* of the trapezium coincides with that of the triangle, two of whose sides are the diagonals, and the third side connects the points on these diagonals which are at the same distances

from the corners of the trapezium as is the intersection of the diagonals themselves. 4. A circle can be described about a trapezium if its opposite angles are supplemental, or if the sum of the rectangles under the opposite sides is equal to the rectangle under the diagonals. The converse propositions also hold. 5. A circle can be inscribed in a trapezium, if the sum of one pair of opposite sides is equal to that of the other pair, and conversely.

Trapezius. In Anatomy, a muscle situated immediately below the integuments of the posterior part of the neck and back. Its principal action is upon the scapula; and it also acts upon the neck and head, drawing the latter backwards, and turning it on its axis.

Trapezoides (Gr. τραπεζοειδής). In Anatomy, the *trapezoides* is the second bone of the second row of the carpus.

Trappists. The name of a religious order which still exists in Normandy. It was founded in 1140 by a count de Perche, in a deep valley called La Trappe (whence the name of the order), and has survived all the changes and revolutions of France. The rules of this order are of the strictest kind. It was, however, far less celebrated under its original foundation, than from the reform which it underwent under the celebrated abbé de Rancé, in the reign of Louis XIV. The history of this celebrated man is well known: he was a gallant and daring profligate, whose conversion was owing to the sudden death of a mistress. His character and reform were a favourite subject of discussion in the court of that king in its last and devout period; and he was himself the fashion, and much consulted and thought of by the fashionable devotees of the time. Perhaps the best notices of him will be found in the *Memoirs* of Saint Simon, who reverenced him, but was too clear-sighted to idolise anyone. His rule was of the austerest sort, enjoining, among other severities, absolute silence for a considerable period. At the Revolution, the community of La Trappe was dispersed: many members escaped to England, and were received by Mr. Weld, the owner of Lulworth in Dorsetshire. There are now several congregations of Trappists. Many of the stories told of the austerities of La Trappe—e.g. that each of the monks is employed in digging every day a portion of his grave, &c.—are fables. But the main features of the discipline, the enforced silence, and the complete seclusion from the world, are as commonly reported.

Traumatic (Gr. τραῦμα, *a wound*). Relating to wounds; hence the traumatic balsams and ointments of old pharmacy.

Traveller. In Naval affairs, a ring or hoop which slides along a rope or spar.

Traveller's-tree. One of the names of *Urania speciosa*.

Traverse (Lat. transversus, *laid across*). In Fortification, short earthen parapets placed at intervals between the guns in a field-work, or across the terreplein of the covered way of a fortress, &c., are called *traverses*.

Traverse. In Law, a name given to a plea containing a denial of some matter of fact alleged on the other side, and offering to refer the matter to the decision of a jury. [Pleading.]

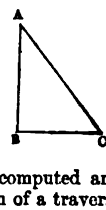
In cases of misdemeanour, where the defendant postponed the trial of the indictment until the next sessions or assizes, he was said to traverse the indictment, but this proceeding was abolished by stat. 14 & 15 Vict. c. 100, by which other provisions for the adjournment of trials were made.

Traverse Sailing. In Navigation, sailing on different courses in succession. The method of reducing such compound courses and distances into an equivalent single course and distance is called *resolving a traverse*. The reduction may be effected either by geometrical projection or trigonometrical computation; but it is generally performed by inspection with the aid of a Traverse Table.

Traverse Table. In Navigation, the tabulated form in which the northing, southing, easting, and westing are made on each individual course and distance in a traverse, for the purpose of finding readily the difference of latitude and departure made upon the whole; the difference between the sums of the northings and southings being the *diff. lat.*, and between the sums of the eastings and westings the *departure*.

The northing, southing, easting, and westing are generally taken by inspection from a table which contains the parts of a right-angled plane triangle corresponding to a given acute angle, and a hypothenusal line of every unit in length from 1 to 300, and sometimes to 500; an extent sufficient for the wants of the practical navigator. This table itself is also called a *traverse table*, from the facility which it affords in resolving a traverse; but it may be applied advantageously to many other purposes.

In the annexed figure, A B C is a plane triangle right-angled at B; and if A B represent a portion of the meridian (considered a straight line), passing through A, and A C the distance from A to C, then the angle A is called the *course*, A B the *difference of latitude*, and B C the *departure*; and to given values of A and A C the corresponding values of A B and B C, being computed and entered in a table, form a portion of a traverse table.



The table is thus constructed to A C and angle A as *arguments*, the angle being taken to every degree and every quarter point of the compass, and the hypothenuse to every integer from unity to as high a number as may be thought requisite. But, the table being formed, any two elements which geometrically determine the triangle may be assumed as the given one, and the other found by inspection from the table. But the use of the table is not limited to the solution of right-angled triangles only; for every case of oblique triangles may be solved by means of it.

Traversers. [RAILROADS.]

Traversing Platform. In Artillery, a platform to support a gun and carriage, which can be easily traversed or turned round a real or imaginary pivot near the muzzle by means of its trucks running on iron circular racers, let into the ground; there are *common*, *dwarf*, and *casemate* traversing platforms.

Travertin. A white calcareous stone, formed by the action of mineral springs either at the bottom of water upon the mud and other material there accumulated, when they issue under water, or thrown down from chemical solution in the waters of such springs in sheets or strata, when the waters thus loaded approach the surface of the ground and enter into new combinations.

Travertin is a modern deposit extremely abundant in volcanic districts. It is, however, not confined to recent volcanic districts, being abundant near extinct volcanoes and traceable elsewhere. Those springs often called *incrusting springs* or *petrifying wells* are such as form these deposits. Loaded with carbonate of lime, and continuing to flow from century to century, they are capable of producing results in the way of deposit very much larger than could be thought possible.

So large is the deposit of travertin in the Italian peninsula, where it has been chiefly observed, that the whole ground in some parts of Tuscany and the slopes of many of the hills are thickly coated with it or TUFA, so that the ground sounds hollow under the feet. As much as thirty feet thick of such accumulation has been deposited at the baths of San Filippo in twenty years, and here medallions or casts of coins and other objects are rapidly made.

It is not unusual to observe a perfect concentric structure in the travertin, showing the mode of its formation in successive layers. Small oolitic and pisolitic structure is also thus obtained. [OOLITE; PISOLITE.] Horizontal beds of tufa and travertin are seen at Tivoli from four to five hundred feet in thickness. [TIBER STONE.]

Travertin furnishes a good durable building stone, which was much used by the ancient Romans.

Travestie (Fr. travestir, *to disguise*). In Literature, a word used in the same signification as parody. [PARODY.]

Treacle (Fr. thériaque; Span. triaca; Gr. θηριακά, sc. φάρμακα, literally *remedies against the bits of beasts*). The viscid brown syrup which drains from the sugar in the refining moulds. Its specific gravity is generally 1·4, and it contains on the average 75 per cent. of solid matter. (Ure's *Dictionary.*)

Treadmill. An invention for giving hard labour to persons imprisoned for crime.

Its usual form is that of a cylindrical wheel of about 5 feet diameter, and 16 feet long; and many such wheels are sometimes coupled together. The circumference is furnished with twenty-four equidistant steps, on which the prisoners are made to work on the mill. Each individual treads in a separate compartment, boarded off so that no intercourse can take place between the parties at work at the same time.

All mounting the first step together, their weight sets the wheel in motion, bringing down the step trod upon; when they step up to the next one, which descends in the same manner, and so on, producing a continuous rotatory motion in the wheel, which may be applied as the moving force to a mill for grinding corn, or in turning any other machinery.

The prisoners at work on the wheel are assisted and supported by a hand-rail before them. The wheel makes about two rounds per minute, which is equivalent to a vertical ascent of about 32 feet per minute, and this is about the maximum of labour usually permitted on the wheel. These machines were introduced into all the great prisons in England and Wales; but in some cases a crank handle, which the prisoner is made to turn, is now employed in preference.

Treason or **High Treason** (Fr. trahison; Lat. traditio, *a betrayal*). By the statute 25 Edw. III. c. 2, the limits of this great offence were first accurately defined; and although subsequent enactments at different periods widely enlarged the range of actions which might be drawn within its penal character, yet most of these have been regarded as encroachments upon the principles of our jurisprudence. To compass the death of the king, queen, or king's eldest son and heir; to violate the king's wife or daughter, or the wife of the heir apparent; to levy war against the king in the realm; to assist the king's enemies in the realm or elsewhere; to counterfeit the king's privy seal; to counterfeit the king's money; to slay the chancellor or other high judicial magistrates; these are the seven species of treason constituted by this Act. The many fresh species devised during the troubled periods which followed that reign, and by the arbitrary genius of Henry VIII., were repealed in the first year of the reign of Queen Mary. Of new treasons since created by analogy to those which were previously so considered, the principal now remaining are those directed against the impugners of the Act of Settlement; and against persons intending the death, &c., of the sovereign, and declaring such intention by printing, writing, or overt act. (4. Steph. Bl. 245.) To counterfeit the king's seal or money is not now treasonable. The law relating to the manner of trial in treason is in many respects peculiar; the barbarous adjuncts to capital punishment in such cases have been long disused. By a recent statute (11 & 12 Vict. c. 12), commonly called the Treason Felony Act, under which the maximum punishment is penal servitude for life, many treasonable offences may be tried and punished as simple felonies.

Treason, Misprision of. This crime is defined to be the bare knowledge and concealment of treason, without any degree of

consent thereto; for any assent makes the party a principal traitor. [MISPRISION.]

Treasure Trove. By the Common Law of England, all gold and silver plainly derelict by the former owner, and not traceable to any representative of that owner, was the property of the crown. The rule, it appears, is derived from the strictly limited character of all feudal grants. The king's gift never conferred larger rights than were actually expressed; and hence, when, as in some manors, more enlarged powers or rights were conferred than was customary, such special advantages were always expressed, and never implied. In general, then, a grant only bestowed a permanent usufruct of the soil, the inferior metals being included under the ordinary right to dig or commit waste, while the more precious metals were reserved to the crown.

The duty of investigating all cases of treasure trove was one of the functions of the coroner, an exceedingly important officer in the middle ages, who was bound to be faithful to the crown in whose interests he acted, but who, being elected by the freeholders of the county, in much the same way that the seneschal of a manor was often elected by the free tenants, was in one sense independent of the crown.

For a long time the importance of treasure trove as an object of revenue has declined, and the privilege of the crown, having become odious since public opinion has recognised a larger ownership in land than is consonant with the feudal theory, has seldom been exercised, except to secure antiquities and rare coins for the British Museum. These, we believe, it has always purchased at a valuation from the finders or owners.

The Treasury has now power to remit the crown's rights in treasure trove. The security of property which we have enjoyed since the Revolution has, however, put a complete stop to the practice of burying treasure in Great Britain. But down to a late period the practice was common in Ireland, and is, perhaps, not yet altogether abandoned in that country; and it is also common in some of the Continental states. Neckar mentions that in France, under the ancien régime, the vassals of many of the nobles, afraid of subjecting themselves to the violence of their masters, buried all the money they could scrape together; and during the anarchy and brigandage of the Revolution, vast sums were thrown into the earth. The well-informed Russian economist, M. Storch, mentions that the practice of burying treasure is still extremely prevalent in Germany, Italy, and Russia; and it must necessarily be more or less prevalent in every country exposed to the ravages of war, or where the rights of property are imperfectly protected. But it is chiefly in the despotic states of Asia, and in Turkey in Europe, that the burying of money is carried to the greatest extent. *There* every individual estimates his wealth, not by the stock or capital he has lent to others, or has employed in the great work of production, but principally by the amount of the treasure he has been able to conceal; and every poor man deposits in the earth whatever he can contrive to withdraw from the grasp of his avaricious masters. Mr. Scrafton, in his valuable tract on Hindustan, considers that the universality of this practice, and the quantity of the precious metals which must in consequence have been lost, have been a principal cause of the long-continued drain of specie to the East. From the discovery of the American mines down to a very late period, the greatest portion of their produce has been directly or indirectly exported to Turkey, Hindustan, and other Eastern countries; and yet it is said that the precious metals do not seem to have become more abundant in those countries, or the prices of commodities to be materially increased. But, without attempting to investigate the precise degree of credit that ought to be attached to this statement, it is abundantly certain that the want of security which has caused this locking up of so large a quantity of capital must be one of the main causes of the poverty and wretchedness in which the people of India, Persia, Turkey, &c. are involved.

Treasurer, Lord High (Fr. trésor, Span. tesoro, Gr. θησαυρός, *treasure*). Formerly the third great officer of the crown in England. The office is now executed by five persons, styled the *lords commissioners of the treasury*. [TREASURY.]

Treasury, Board of. In England, the board to which is intrusted the management of all matters relating to the sovereign's civil list or other revenues. This office was formerly committed to the lord high treasurer; but in modern times a lord high treasurer has not been appointed, the duties of his office being executed by a board of five lords commissioners. The chief of these, or first lord of the treasury, is generally the prime minister for the time being; his office, however, in relation to the department itself, is little more than nominal; its practical head being the Chancellor of the Exchequer. The salary of the first lord of the treasury is 5,000*l.* per annum; that of the Chancellor of the Exchequer is of the same amount; the three junior lords have 1,000*l.* a year each. There are two joint secretaries of the Treasury, one of whom manages the details of ministerial business in the House of Commons, and is familiarly termed the *whip*.

Treating (Fr. traiter, Lat. tracto, *to handle*). Treating at parliamentary elections, by corruptly providing meat, drink, entertainment, or provision, is now a substantive offence, punishable by a fine of 50*l.*, besides being a ground for avoiding the election. (Stat. 17 & 18 Vict. c. 102, and amending Acts.)

Treaty (Fr. traité; Ital. trattato, from Lat. tractatus, *a handling*). In Law, an agreement between two or more independent states. Grotius (*De Jure Belli et Pacis*, l. ii. ch. xv. s. 5) divides treaties into two classes: those which turn on things to which the contracting parties are already bound by the law of nature,

such as mutual amity, commerce, &c.; and those which contain stipulations for something more, such as treaties regulating boundaries, conceding particular powers, &c. The municipal constitution, in every state, determines in whom resides the authority to make and to ratify treaties. In most monarchies it is vested in the sovereign; in republics, in the chief magistrate, senate, or executive council; in federal states, sometimes exclusively in the federal authority, as in the United States; but in the Germanic federation (while existing) the particular states retained the right of making treaties of alliance and commerce not inconsistent with the fundamental laws of the confederation. In order to enable a public minister or other diplomatic agent to conclude and sign a treaty, he must be furnished with a full power; and when so concluded, the treaty is binding on the state, in the same manner as an agent is bound by the act of his principal. But the question how far, and in what cases, ratification is necessary, has been the subject of much debate among writers of international law. It is usual to reserve a power to ratify in the treaty itself. It is necessary also, in most constitutional governments, that the sanction of the legislative body should be subsequently given to treaties of commerce, or treaties imposing taxes on the people, entered into by the executive. Thus the government of Great Britain, when making treaties, granting subsidies, &c., usually stipulates that the sovereign will recommend to parliament to make the grant necessary for the purpose; but under the constitution of the United States, it has been thought that congress is bound to sanction treaties in general made by the president with the advice and consent of the senate. Treaties have been divided into *real* and *personal*: the former of which are said to bind the contracting parties, independently of any change of the sovereign or the rulers of the state; the latter are made with express reference to the person of the actual ruler. But treaties properly so called, as of friendship and alliances, commerce and navigation, even if perpetual in terms, are said to expire: 1. In case either of the contracting parties cease to be an independent state; 2. When the internal constitution of government is so changed as to render the treaty no longer applicable. In this they differ from what are called *transitory conventions*, which pass from one government to another; such as treaties of cession, boundary, &c. (Wicquefort, book ii.; Vattel, book ii.; Schoell, *Hist. de Traités de Paix*, 4 vols. Brussels 1817.)

It was at one time an international custom that belligerents should, on the breaking out of a war, make a public and solemn proclamation that the obligation of treaties between them had ceased. That custom has become obsolete. In its place has arisen the general maxim that war ipso facto abrogates treaties between the belligerents. But international jurists now place important limitations on this maxim. Its extent was much discussed in 1814, on the occurrence of the question, whether the rights of fishery accorded by Great Britain to the United States by former treaties were abrogated by the war of 1812: England maintaining the affirmative. It cannot be said that any satisfactory general view of the solution of this important problem has been arrived at. (Phillimore *On International Law*, part xii. ch. ii.)

Treaty, Commercial. The facts that particular counties are specially favoured in the growth or manufacture of special products, or are situated favourably for general commerce, or possess a natural control over certain districts from which articles of great importance or general demand are procurable, or are possessed of certain political, strategic, or similary important capacities, are reasons, early appreciated in political history, for diplomatic negotiation. The earliest treaty in existence, between Carthage and republican Rome, is quoted by Polybius, and is dated in the year which is assigned as the second after the expulsion of the Tarquins. It is almost entirely commercial in character. Commercial treaties are referred to by Aristotle (*Nicomachean Ethics* v. 5) as familiar facts. The exclusion of Megara from the markets of Athens and her dependencies, equivalent to a prohibition of nearly all foreign trade with Eastern Europe and Western Asia, was one of the grievances quoted as a plea for beginning the great Peloponnesian war. In point of fact, such formally enacted commercial regulations were inevitable in the singular interpolitical system which was so marked a feature in ancient Greece, while the motive was less prominent and operative under the absorbing military despotism of Rome.

The age of the Hanseatic League (about 1250) was the period in which such a system was renewed in Europe. This famous confederation, framed for the purpose of securing political and commercial liberty, by joint resistance to the outrages of feudal tyranny, was a great commercial treaty, in which the contracting parties bound themselves to common action, to a system of common defence, and common representation for the purposes of the league. The decline of this league began when the disorder, confusion, and rapine, which it was intended to prevent, were repressed by the agencies of a growing civilisation. With such a civilisation, grew also the conviction that the strength of a nation lay in the magnitude and security of its foreign commerce, and the view that the direction of this commerce was an important object in diplomacy.

Among European states, none appear to have acted with so much steady perseverance in the direction of what may be called commercial diplomacy as this country. It is not difficult to explain the reason, and (as economical enlightenment is comparative) to recognise the cause of the great prominence which this country assumed in the commerce of the western world five centuries ago, notwithstanding the caprice with which its acknow-

ledged policy was modified or suspended, or its progress thwarted by purely political intrigues. England at this time was well-nigh the sole producer of wool. The local police, all things considered, was excellent: property was sacred, and rapine rare. It may be that, at this period, sheep-farming for the purpose of wool was rare on the Continent; it is certain that it was full of risks, under the feudal anarchy which then impoverished Europe. It is impossible to keep sheep unless property is made safe by a vigorous executive; and there is abundant evidence that the peace was kept better in England than in any European community whose industry was specially agricultural—better perhaps than in any community whatever. But just opposite to the English coast and the best settled part of the country, were the factories of the Netherlands, the spinners and weavers of Liége, Ghent, and other towns. Between these regions and our country the most intimate commercial relations existed. The Flemings were invested with peculiar privileges, and invited to settle in England; and, by the close of the thirteenth century, so intimate were the relations between the two countries, that Norfolk, in which these Flemings had settled in great numbers, was by far the richest county in England, and was the seat of its most important manufactures.

The early French campaigns of our Edward III. were connected diplomatically with the commercial relations then existing between the Flemish weavers and the English wool staplers. The patriotism or the intrigues of Arteveldt, manifestly directed towards checking the feudal prerogatives of the counts of Flanders and the bishops of Liége, found an obvious and ready machinery in the mutual interests of the two countries. A century and a half after the events which preceded the battle of Crecy, those intrigues of Mary, duchess of Burgundy, which aimed at distressing Henry VII., the successful enemy of her house, were thwarted by the commercial treaty negotiated between the Flemish towns and the wily king of England, a treaty known for many a day afterwards by the name of the *Intercursus magnus*. During the wars of Henry V. and Henry VI. the dukes of Burgundy were attached to the English alliance quite as much on commercial grounds as they were stimulated by antipathy to the Armagnacs.

The acceptance of the mercantile system [POLITICAL ECONOMY], and the policy which followed its acceptance, bore the fullest fruits in the commercial treaties which were negotiated from the middle of the seventeenth century down to the middle of the nineteenth. The general purpose of these treaties was—to secure a market for our *exports*, and to admit reciprocally the exports of some nation with whom the treaty was concluded. Coupled with this arrangement, there was almost always some political alliance contemplated, some favour stipulated, which would never have been granted, except on the presumption that the admission of our exports was a great public advantage. The nation was taught that a less advantageous import trade was counterpoised by a more advantageous export trade; that the latter was an aid to capital, and an incentive to labour; that the principal object of trade was to export as much as possible; and that the grant of this kind of indirect bounty on home produce was an act of the highest political wisdom. It will not be difficult to show that it was an act of consummate folly.

It is of the greatest importance to a producer to know which is the market for which he produces, and he finds this out most surely by the freest intercourse of trade. Any guidance, any tutelage, any bounty—and a favoured market is a bounty—instead of aiding him in his interpretation of the market, bewilders and deludes him. The fact that his capital is diverted into such and such a channel by these indirect means, would be (from the general economical law, that the profits of equal capitals, other things being equal, are equal) no advantage to him; while the diversion of capital from more productive to less productive objects involves an inevitable loss to the aggregate capital of the community. The purport of the celebrated Methuen treaty, negotiated between England and Portugal in 1703, was the introduction of English woollens into Portugal. But the English woollen trade, during the greater part of the eighteenth century, was not in a healthy condition, and every kind of expedient was vainly attempted in order to stimulate and sustain it. Capital which might have been better employed was turned into a particular channel, and forced in an unnatural direction; and again, the general consumer, in order to secure these delusive advantages to the producer of some favoured article, is obliged, by way of compensation, to take certain goods which are dearer and less valuable than those with which an open market would have supplied him. Thus, in order to introduce woollens into Portugal, the English government agreed to tax all wines produced from other countries at the rate of one-third more than it taxed Portuguese wines. Such a proviso, as it excluded the most important, and up to the time at which the treaty in question was negotiated, the most familiar produce of France, naturally begot a policy of irritation, and, as a consequence, retaliatory restrictions. The trade between this country and France, which should have been large, was reduced to insignificance, and the two nations became estranged. In brief, no bargain could have been concluded on the basis of such commercial treaties as were in fashion up to within the last twenty years, without inflicting a double loss, one to capital, the other to consumption.

The excessive anxiety to stimulate exports is an economical error. A nation cannot, it is true, be indifferent to the restrictive or pro-

hibitive tariffs of other countries, since (even though, as is commonly the case, the tax levied in the country adopting such a protection or restriction may be paid by the consumers of such commodities as are imported legally, and a prohibition, if the article be in demand, will, even under circumstances very unfavourable for such transactions, be evaded by the practice of smuggling) such hindrances diminish demand, and render the interpretation of supply difficult. But the grant of facilities to imports is of much greater consequence. Every nation, however wedded to protective theories, desires to export; but unless it resolves on accumulating specie, and so raising prices by depreciating its currency, it must sell its exports for goods. So general is this desire to export, that governments rarely venture on export duties, and learn that they can fairly enough leave the exports to take care of themselves.

The system of the commercial treaties formerly negotiated has been exploded in this country, owing to the acceptance of free-trade principles. Treaties have been completed between this and other countries on a theory very different from that which sought to secure special favours for the trade of the contracting parties. The character of this later diplomacy may be best understood by taking a particular instance; for example, the treaty negotiated by the late Mr. Cobden between this country and France—a treaty the principle of which has been sometimes impugned by some who have considered that it involved a departure from free-trade principles, and by others who have thought that it tied the powers of the government in limiting the fiscal expedients of those which might be adopted. But neither of these charges was just.

Mr. Cobden, who was thoroughly acquainted with the nature of the trade between this country and France, and was alive to the excessive restraints which protectionist and retaliatory laws had put on the commercial intercourse between two countries which should enter into mutual relations to their manifest mutual advantage, suggested to Lord Palmerston and Mr. Gladstone, that, in his opinion, arrangements might be entered into, consequent on certain projected changes in the English tariff, which would partly increase the trade between the two countries. He did not suggest that any advantage should be given to France over other communities, but only that the alterations in our system—alterations which might very likely be made even if France were unwilling to negotiate—should, if possible, be turned to diplomatic account. It is clear that so long as any portion of the revenue of this country is derived from import duties, it will always be possible to adapt these duties to the interests of exporting countries, and therefore to make them a plea for fiscal concessions. We, it might be argued, adopt free trade as our rule; but we raise a revenue, partly from internal sources, partly from consumable articles of foreign growth. If no revenue were raised from these latter objects, we could not, it is true, do more than allege reasons in favour of our policy; as we do raise such a revenue, we are able, without departing from this policy in the least, to accommodate the method of this revenue to the exports of such countries as can supply us with what we need, but who will also meet us by relaxations in their fiscal methods. Such a proceeding is simply that of instructing a community that if they want to sell, they must buy; a position which may be manifest enough to some, but which is very slowly appreciated by such states as are devoted to protection. And although the negotiators of the treaty bound the nation to a certain course of procedure in future, the obligation was only not to do that which no government in this country would ever dream of proposing.

This mode of arranging the commercial relations of two countries has been ridiculed as a mere *missionary* act. But if diplomacy, while it abandons force, employs remonstrance, appeals strongly to mutual interests, attacks the arguments alleged in favour of an unsound policy, predicts the advantages of one course of action, and the evils of another, upon questions which are purely political, it is hard to say that similar representations should not be made when the matter in debate is simply commercial. Not, indeed, that intimate commercial relations are without a great political interest. The policy of insulation, of prohibition, of protection, is a war policy, full of danger and menace. But the more thoroughly the commerce of two countries is knit together, the more effectual are the guarantees of amity, good will, and peace, the more remote is the risk of quarrel. We cannot doubt that the anxiety which all political parties in this country feel for the preservation of peace, the determination which all evince to treat international questions with an increased regard to public law and morality, and to abstain as far as possible from menace or armed intervention, are due to the intimate commercial relations which have been established between this and other civilised communities. And if it be the case that extended commerce is a powerful pacificator, it is surely just, sound, and right that diplomatic action should be directed as far as possible to the developement of such causes as will lead to friendliness among nations, and to the reciprocity of advantages.

The commercial treaty with France has borne considerable fruits. The trade between the two countries has doubled since it was negotiated; and, far from depressing French goods, with which English products were to compete actively, the result has been that those fabrics and manufactures, of which the continued production, in the eyes of the French protectionists, would be imperilled by the treaty, have actually increased in greater ratio than even those commodities for which the treaty was previously intended to create a more abundant demand.

For the commercial treaties at present existing, and the effects which they produced on trade, see *Commercial Dictionary*, art. 'Treaty, Commercial.'

Treble (Fr. triple). In Music, the highest part in a concerted piece. Thus we say, a treble violin, a treble hautboy, &c. In vocal music, this part is sung by boys or females. The treble is divided into first or highest treble, and second or low treble.

Trebuchet (Fr.; Low Lat. trabutium). A warlike engine of the middle ages, used to throw stones, fiery material, and other projectiles employed in the attack and defence of fortified places by means of counterpoise. At the long end of a lever was fixed a sling to hold the projectile; at the short end a heavy weight, which furnished the necessary moving force. Experiments with engines of this nature were made by direction of the emperor Napoleon III., which are detailed in his *Etudes sur le Passé et l'Avenir de l'Artillerie.*

Treckschuyt (Dutch *track ship* or *boat*). The covered boats drawn by horses or cattle, and used for the conveyance of goods and passengers on the Dutch and Flemish canals, are so called. For an admirable description of the accommodations and management of the *treckschuyt*, now rapidly falling into disuse from the introduction of railways, see Murray's *Handbook for Northern Germany*.

Tree (A.-Sax. treo, perhaps akin to Gr. δρῦς, *a timber-tree*, especially *an oak*). Any woody plant of perennial duration, which rises from the ground with a trunk. To form a tree, the plant must acquire some considerable size, and be furnished with a trunk or single stem by which its branches or limbs may be supported. It differs from a shrub, which is a woody plant of smaller stature, in having a trunk; and it is the presence of this solid mass of wood which gives their especial utilitarian value to trees, furnishing, as many of them do, the timber which is applied to so many useful purposes.

Most of our hardy and indigenous trees are *deciduous*, i.e. they cast off their leaves in autumn, and their twigs and branches remain denuded till the following spring. To this class belong the well-known Oak, Ash, Elm, &c. Some trees, however, retain their clothing of foliage through the winter, and being at no time denuded, are called *evergreen*. To this group belong the Pine, Fir, Cedar, &c.

Trees may be, again, divided into *Ornamental Trees* and *Timber Trees*. The first of these groups is a numerous one, including subjects which afford great variety both of blossom and foliage, as the Tulip-tree, the Lime, the Horse-chestnut, some kinds of Oaks and Elms, the False Acacia, or Locust-tree, and many others. The second is also an extensive group, and may be subdivided into three: viz. coniferous or resinous trees; hard-wooded trees not resinous; and soft-wooded trees. Coniferous trees include many kinds of Pine and Fir, Larch, &c. The chief hard-wooded non-resinous trees are Oak, Chestnut, Ash, Elm, Beech, Horn-beam, Walnut, Sycamore, Locust, Birch, Apple, Pear, Cherry, Laburnum, Holly, and Yew. What are called soft-wooded trees comprise Lime, Horse-chestnut, Alder, and various Poplars and Willows.

Among the timber trees of tropical countries, the wood of which is imported for various uses, occur Mahogany, Rosewood, Teak, Sâl or Saul, Cedar, Ebony, Satinwood, the Gum-woods of Australia, African Oak, and many others. [ARBORICULTURE.]

Tree Fern. The name applied to those ferns which form erect trunks like the stem of a tree. They chiefly belong to the genera *Cyathea*, *Alsophila*, and *Dicksonia*.

Tree-hair. A name sometimes given to the dark wiry pendulous entangled masses of a lichen, *Cornicularia jubata*, which is not uncommon on trees in subalpine woods.

Tree-like. In Botany, this term is applied to plants which resemble a tree, but are very small. [DENDROID.]

Treenails. In Naval language, wooden bolts by which the planks of a ship's bottom are secured to the timbers.

Trefoil (Lat. trifolium, from tres, *three*, and folium, *a leaf*). In Architecture, an ornament of three cusps in a circle; resembling three-leaved clover.

TREFOIL. A name given in English to different kinds of three-leaved plants. White Trefoil is *Trifolium repens*; Yellow Trefoil is *Trifolium minus*; Black Trefoil is *Medicago lupulina*; Bird's-foot Trefoil, *Lotus corniculatus*. These plants are all used for the food of cattle. The French word *trèfle* has a similar application.

Tremando or **Tremolo** (Ital. *trembling*). In Music, a direction for one of the graces of harmony, which consists in a reiteration of one note of the chord: this, however, applies more directly to the word *tremolo*, whilst the *tremando* is a general shake of the whole chord.

Tremandraceæ (Tremandra, one of the genera). A small order of hypogynous Exogens, referred to the Sapindal alliance, and consisting of heath-like Australian shrubs, chiefly characterised by regular flowers, with four or five valvate sepals, as many spreading petals, twice as many free hypogynous stamens, anthers opening in terminal pores, and a free ovary, usually two-celled, with one, two, or rarely three pendulous ovules in each. The order, although small, is perfectly distinct in habit and character, having some affinity with *Polygalaceæ*, but is at once distinguished by its regular flowers.

Trematodes (Gr. τρηματώδης, from τρῆμα, *a hole*). The name of an order of Sterelminthans, or parenchymatous Entozoa, comprising those which have organs of imbibition and adhesion in the form of suckers.

Tremella (Lat. tremo, *I tremble*). A jelly-like plant of the lowest organisation, found in damp walks and similar situations. It is composed of a thallus containing microscopical

spores, and is closely allied to the plants called *lavers*.

Tremenheerite. An impure Indian Graphite, named after Major-General Tremenheere.

Tremolite. A variety of Hornblende, which occurs both crystallised and in slightly elastic fibres in the limestone of Glen Tilt, and in many parts of Scotland. It is a silicate of iron and magnesia, and is named after the Tremola Valley in Switzerland, the locality where it was originally found.

Trench Cart. In Artillery, a small cart, for single draught, used for transporting mortars and their beds, &c. in the trenches and elsewhere.

Trench Cavaliers. In the attack of a fortress, the high parapets of the single saps which are pushed along the slope of the glacis; they should be raised high enough to command the salient places of arms.

Trenches (Fr. tranchée). In the attack of a fortress, the approaches or excavations, made for the purpose of covering the advance of the besiegers. They are from six to ten feet wide, and about three feet deep, the earth taken out forming a parapet.

Trent, Council of. In Ecclesiastical History, a council assembled by Paul III. in 1545, and continued in twenty-five sessions, until 1563, under Julius III. and Pius IV. This celebrated council was convoked at a period when the Christian world was agitated by the early efforts of the reformers; and its most important decrees have therefore reference to the points on which the controversies of the Reformation chiefly turned: e.g. transubstantiation, image-worship, and the authority of the pope. The authority of these decrees (except so far as the more strictly doctrinal part of them is embodied in the creed of Pope Pius IV.) has been much debated among Romish ecclesiastics. In Germany, Poland, and Italy, they appear to have been adopted from the beginning without restriction; in Spain only with a reservation of the rights of the monarch; in France they have never been solemnly received. The more important portions of them, which contain the rule of faith, may be regarded as expressing the belief of the Roman Catholic church at the present day. The famous history of Paolo Sarpi is in many respects a noble work. That of Cardinal Pallavicino represents the view of the less moderate party among Roman Catholic theologians. (Mosheim, vol. iii.; Robertson's *Charles V.*; Hallam's *Introd. to the Literature of Europe*, vol. ii.; Ranke's *History of the Popes*.)

Trent Sand. [Rotten Stone.]

Trepan. A circular saw for perforating the skull. The term *trephine* is also applied to a similar but improved form of the instrument. (Cooper's *Surgical Dictionary*, art. 'Trephine.')

Trepang. [Holothuria.]

Trespass (Nor. Fr. trespasser, from Lat. trans, and passus, *a pace*). In Law, strictly any transgression of the law less than felony or misprision of felony; but the term is generally used to signify any wrong or damage done by one private person to another. *Trespass vi et armis* is where an act is done which is in itself an immediate injury to another's person or property; such as assault and battery, or breaking and entering a house or close. *Special trespass*, or *trespass on the case*, is where an act is not immediately injurious, but only by consequence and collaterally. Trespass is a personal action of tort, and lies for injuries of a very miscellaneous character.

Tressure. In Heraldry, a border running parallel with the sides of the escutcheon, which should contain about one quarter of the bordure. It is generally either double or triple, and has usually fleurs-de-lis, arranged in opposite directions alternately, perpendicular to the length of the tressure; it is then called *flory counter-flory*. The tressure forms part of the royal arms of Scotland, and of those of many noble Scottish houses.

Trestle (Fr. trêteau). A piece of timber supported at each end by legs. Two or more of them are used for carrying a bridge, called a *trestle bridge*.

Trestle-tree. Two bars of wood or iron at the mast-head, fitting on the shoulders of the mast, passing lengthwise of the ship, and holding up the cross-trees, on which and on the trestle-trees themselves the top is laid.

Tret (probably from Lat. tritus, part. of tero, Gr. τείρω, *I rub away*). In Commerce, an allowance of four pounds in every 104 lbs. for the waste which certain kinds of goods are liable to from dust, &c.

Trewiaceæ. An order formerly proposed by Lindley for the genus *Trewia*, which he has since, with other botanists, referred to *Euphorbiaceæ*.

Triad (Gr. τριάς, τριάδος). In Music, a compound of three sounds, which, being naturally divisible into two thirds (one major and the other minor, constituting a fifth in the whole), has received the name of the *harmonic triad*. Its name is founded on its being formed of a third and a fifth, which, with the bass or fundamental sound, make three different terms.

Triads. In Cymric Antiquities, the *Triads of the Welsh Bards* are poetical histories, in which the facts recorded are thrown into the form of triplets. Thus, to take the commencement of the first Triad as an example. 'Three names have been given to the Isles of Britain since the beginning: Clas Merddin, Til Inys, and Inys Pridain.' The Triads are supposed to be of no greater age than the reign of Edward I., although they probably contain fragments of old history. (Turner's *Anglo-Saxons*, vol. i.)

Trial. In Common Law, the examination and disposal of an issue or fact, either in criminal or civil proceedings. Trials are by *certificate*, by *inspection*, by the *record*, and *per pais*, i. e. a jury. The first three are of a pecu-

liar character. Trial by certificate is where the evidence of the person certifying is the only proper test of the issue; as, the customs of the city of London are to be tried by the *certificate* of the mayor and aldermen, &c. Trial by inspection is said to be where the judges personally examine and decide the question in dispute; a practice long obsolete. Trial by the record is where the point at issue being whether or not a certain record exists, or certain averments in it, it is decided by the production of the record itself. But the ordinary trial of all facts, with these very rare exceptions, is by a jury, summoned to try the issue raised by the pleadings. Trials at bar of civil actions are those which take place before all the judges of the court of which the record is; the original, and, as it were, direct mode of trial, from which all others are variations, although it is now very rare in practice. In ordinary cases, it has been long superseded by trial at Nisi Prius (since 13 Edw. I.). [Nisi Prius.] A trial at bar is now only granted on special grounds. These are the ordinary modes of disposing of issues raised on records in the superior courts; and trials of actions in courts of limited jurisdiction are governed by the same general rules. Criminal trials are had in like manner when an issue of fact (generally guilty or not guilty) is raised by the pleadings. *New trials*, in civil cases, are granted where the court sees reason to be dissatisfied with a verdict, on the ground that evidence was improperly received or rejected; or that the judge misdirected the jury as to the law applicable to the facts; or that the verdict was against the weight of evidence; or the damages exorbitant or insufficient; or that a party was unfairly surprised; or that fresh evidence has since been discovered; and in some similar cases.

Triamylamine. An organic base derived from ammonia by the replacement of three atoms of hydrogen in the latter by three of the radical amyl.

Triangle (Lat. triangulum). In Astronomy, one of the forty-eight constellations of Hipparchus, situated in the northern hemisphere. The same name is also given to one of the twelve southern constellations formed by Bayer. There is also the *Little Triangle*, added by Hevelius, near the first named. [Constellation.]

Triangle. In Geometry, a figure which has three sides, and consequently also three angles.

Triangles are *rectilineal*, *spherical*, or *curvilineal*. *Rectilineal* or *plane triangles* are bounded by straight lines; *spherical triangles* are formed on the surface of a sphere by the intersection of the planes of three great circles; *curvilineal triangles* are those which are bounded by three curves of any kind whatever.

Triangles receive other distinctive names from the relation of their sides and angles. A plane triangle is said to be *equilateral* when its three sides are all equal; *isosceles* when two only are equal; and *scalene* when all three are unequal. It is called *right-angled* when one of its angles is a right angle; *oblique-angled* when one of its angles is greater than a right angle; and *acute-angled* when each of its angles is less than a right angle; lastly, two triangles are said to be *similar* when their angles are respectively equal, each to each.

The following are some of the properties of plane triangles which it is useful to remember.

1. The greater side is opposite the greater angle, and vice versâ.

2. The sum of any two sides is greater, and the difference of any two sides less, than the third side.

3. The sum of the three angles is equal to two right angles; and if one of the sides be produced, the exterior angle is equal to the sum of the two interior and opposite angles.

4. The sum of the squares on two sides of a triangle is greater than, equal to, or less than, the square on the third side, accordingly as the angle enclosed by those sides is acute, right, or obtuse.

5. The perpendiculars erected at the middle points of the sides of a triangle meet in the centre C of the circumscribing circle. The lines joining the corners to the middle points of the opposite sides meet in the centre of gravity G. The perpendiculars let fall from the corners upon the opposite sides also meet in a point P, on the line CG produced through G so that $GP = 2GC$.

6. The six lines bisecting the interior and exterior angles of a triangle intersect in four points, which are the centres of the inscribed and the three escribed circles.

7. The middle points of the sides, and the feet of the perpendiculars let fall thereon from the angles respectively opposite thereto, all lie in the circumference of a circle which touches the inscribed and escribed circles. [Circle, Six-points.]

In general, a triangle is determined when three of its elements (sides and angles) are given. The exceptional cases are when the given elements are all angles, and when they consist of two sides and an angle opposite to the least of these sides. The latter is the *ambiguous case* of the *solution of triangles*. [Trigonometry.] The geometrical origin of the ambiguity is in the following proposition, which deserves a place in the elements of geometry.

8. If two triangles have an angle of the one equal to an angle of the other, and the sides about two other angles equal, each to each, the remaining angles will be either equal or supplemental.

Triangle. In Music, a small steel triangular musical instrument of percussion, open at one of its angles. It is set in vibration by being struck with a short metal bar.

Triangle, Arithmetical. The name given by Pascal to a table of certain numbers which are usually disposed in the form of a triangle. The first vertical column of the table

contains units only; the second contains the series of natural numbers; the third the series of triangular numbers; the fourth the series of pyramidal numbers; and so on. [FIGURATE NUMBERS.] Thus—

1						
1	1					
1	2	1				
1	3	3	1			
1	4	6	4	1		
1	5	10	10	5	1	
1	6	15	20	15	6	1
&c.	&c.	&c.	&c.	&c.	&c.	&c.

Any number in the table is obtained by adding the number next above it, in the same column, to the number in the same line in the next preceding column; and it will be observed that the oblique diagonal rows, beginning at the left and descending towards the right, are the same as the vertical columns. One of the properties of the table is, that numbers taken on the horizontal lines are the coefficients in the expansion of the different powers of a binomial. [BINOMIAL THEOREM.] For the description and uses of the table, see the Introduction to Hutton's *Mathematical Tables*.

Triangle of Forces. The name given to a theorem in Statics, according to which three forces which, applied to the same point, produce equilibrium are always parallel and proportional to the sides of a triangle, taken in order. The term *polygon of forces* is applied to the general theorem.

Triangle of Reference. Called also *fundamental triangle*. [CO-ORDINATES.]

Triangles, Conjugate. [CONJUGATE POINTS, LINES, AND TRIANGLES.]

Triangular Compasses. Compasses having three legs; two opening in the usual manner, and the third turning round an extension of the central pin of the other two, besides having a motion on the central joint of its own. The instrument is useful in the construction of maps and charts, as three points may be taken off at once.

Triangular Numbers. The series of numbers formed by the successive sums of the terms of an arithmetical progression, of which the common difference is 1. Thus:—

Arithmetical progression .	1, 2, 3, 4, 5, 6, &c.
Triangular numbers . . .	1, 3, 6, 10, 15, 21, &c.

The general term of the series is $\frac{1}{2}n(n+1)$. [FIGURATE NUMBERS.]

Triangulation. The cutting up of the surface of a country into a network of triangles with a view to the construction of a map. [SURVEYING.]

Triarii. The third, last, or veteran rank of infantry in the Roman legion. As these formed the last reserve, the phrase *rem ad triarios redisse* was used to signify that the last stake for victory had been thrown.

Trias. The Geological designation of the lowest and oldest of the secondary or mesozoic deposits. The name is derived from the division of the group into three parts, tolerably well marked on the continent of Europe; but in England the middle part is absent, and the separation between the upper and lower is thus rendered obscure. The rocks are usually known in England as the New Red Sandstone. Fossils are rare, but both plants and animals are indicated. The latter include some very remarkable and interesting reptilian forms. [BUNTER SANDSTEIN; DESCRIPTIVE GEOLOGY; KEUPER; MUSCHELKALK; NEW RED SANDSTONE.]

Tribasic Acids. When an acid, on being brought in contact with a metallic oxide, exchanges three atoms of hydrogen for an equivalent amount of metal, it is termed a *tribasic acid*.

Tribe (Lat. tribus, perhaps akin to tres, and the Sanscrit root bhu, *to be*, and hence to the Æolic τριττὺς = τριττύς, *a third part*). A principal subdivision of the Roman people; but of the origin and nature of this classification little is known with certainty. According to Dionysius, ROMULUS divided the people into three tribes, and each tribe into thirty curiæ. Livy in one place (i. 13, 36) speaks of the RAMNENSES, Titienses, and Luceres, as forming the three centuries of knights; in another (6) he mentions them as the three ancient tribes. SERVIUS TULLIUS is said to have divided the city, as enlarged by himself, into four local tribes, in place of the three hereditary tribes, hitherto existing, the country being divided by him into twenty-six tribes according to Fabius, or thirty-one according to Vennonius. Ten of these tribes are supposed by Niebuhr to have been swept away by the cession of the territory on the Etruscan bank of the Tiber to Porsena, as twenty-one tribes are mentioned by Livy shortly after the battle of Regillus; but Livy mentions only the four city tribes in the reign of Servius, and we do not know what he supposed the whole number to have been. Sir G. C. Lewis adds that Livy's words 'imply that the number of twenty-one for the tribes was voluntarily established in the year 496 B.C. after the battle of Regillus, and without any reference to the war of Porsena.' The futility of Niebuhr's explanation is, in Sir G. C. Lewis's judgment, proved by the fact that, according to Livy, the number of twenty-one tribes remained unchanged for more than a century, whereas the effects of Porsena's war were, according to Niebuhr's own view, soon obliterated; and if the number was diminished on account of loss of territory, it is reasonable to suppose that it would have been increased to its former complement as soon as the territory was recovered. (*Credibility of Early Roman History*, ch. xii. sec. 13.)

But the division of nations or peoples into tribes may be regarded as having been universal, the number of the tribes varying from three, as in some Greek peoples, to twelve, as with the Hebrews. This division, like that of the Celtic clans, was based essentially on a religious foundation, each tribe having its common sacrifices and festivals; and these tribes,

standing on an equality with each other, must be carefully distinguished from the populations which were held in subjection. Thus, the Thessalians had their PENESTÆ, the Spartans their HELOTS; but neither Penests nor Helots were included in the tribal divisions of their conquerors. The Dorians, called in the *Odyssey* Τριχάϊκες, or the people of three tribes, were subdivided originally into the Hyllæans (said to be named from Hyllus, a son of HERACLES), the Dymanatæ, and the Pamphyli, the last named furnishing a parallel to that of the Panhellenes. To these three tribes, others were from time to time added in different places. Thus, eight tribes are mentioned in Corinth, and four in Tegea. The twelve tribes of Elis, reduced to eight by a war with the Arcadians, seem to have been geographical divisions. The Ionian division appears to have been fourfold. Those of Attica, which, according to some traditions, had borne other names, were the Geleontes, the Hoplites, the Argades, and the Ægicoreis. The origin of these names can be accounted for only by conjecture, and the last three are explained etymologically as representing, respectively, the armed men or warriors, the husbandmen, and the goatherds. Of the term Geleontes, no interpretation can be given, and it has been supposed that their name was really Teleontes, and that it had reference either to sacerdotal duties, and thus denoted the priestly caste, or to a payment of rent, and thus denoted the peasantry. Against the former notion, it is urged that Athenian history gives no sign of the existence of any priestly caste, and against the latter that the Teleontes would thus be identified with the Argades. THESEUS, it is said, introduced a new division into Eupatridæ (or nobles), Geomori (or agriculturists), and Demiurgi (or artisans); but the relation of these classes with the tribes has not been precisely ascertained.

Tribometer (Gr. τρίβω, *I rub*, and μέτρον, *measure*). In Mechanics, the name given by Musschenbroek and Coulomb to a sort of sledge or apparatus for measuring the force of friction. [FRICTION.]

Tribromaniline. Aniline in which three atoms of the hydrogen have been replaced by three of bromine.

Tribunal (Lat.). In Roman Antiquities, a raised platform on which the prætor and judices sat in the Basilica.

The tribunal in the camp was formed either of turf or of stone, and from it the general addressed his soldiers, and the council and tribunes administered justice.

Tribune. Properly, as the name denotes, the chief magistrate of a *tribe*. There were several kinds of officers in the Roman state who bore the title. 1. The plebeian tribunes, who are said to have been first created after the secession of the commonalty to the Mons Sacer (260 A.U.), as one of the conditions of its return to the city. They were especially the magistrates and protectors of the commonalty, and no patrician could be elected to the office. At their first appointment the power of the tribunes was very small, being confined to the assembling the plebeians and to the protection of any individual from patrician aggression; but their persons were sacred and inviolable, and this privilege consolidated their other powers, which were finally incorporated with the functions of the other chief magistracies in the person of the emperor. The number of the tribunes varied from two to ten, and each of these might annul the proceedings of the rest by putting in his veto. (Niebuhr's *Hist. of Rome*, 2nd edit. i. 624; Lableterie, *Mém. de l'Acad. des Inscr.* vol. xxxvii.) 2. Military tribunes, said to have been first elected in the year 310 A.U. in the place of the consuls, in consequence of the demands of the commonalty to be admitted to a share of the supreme power. The number of the military tribunes is represented as sometimes six and sometimes three. For above seventy years, we are told, sometimes consuls were elected and sometimes military tribunes; at last the old order was permanently restored, but the plebeians were admitted to a share of it. (*Mém. de l'Acad. des Inscr.* vol. xxxvii.) 3. Legionary tribunes, or tribunes of the soldiers, were the chief officers of a legion, six in number, who commanded under the consul, each in his turn, usually about a month: in battle each led a cohort.

For the difficulties and contradictions which run through the narratives of the institution of plebeian and military tribunes, see Sir G. C. Lewis, *Credibility of Early Roman History*.

TRIBUNE (Fr.). In Modern Political History, the elevated kind of pulpit occupied by members of the French assemblies in order to make a speech; hence, the eloquence *of the tribunes*, in the sense of parliamentary eloquence.

Tribute (Lat. tributum). A sum of money paid by an inferior sovereign or state to a superior potentate, to secure the friendship or protection of the latter. The *black mail*, formerly levied by the Scottish borderers on their less powerful neighbours, for protecting their property from the depredations of caterans, was a species of tribute.

In Roman History, the tributum was a tax on real property, which, according to Niebuhr, was at first paid only by plebeians, the name being used in connection with the Servian tribes. Livy, however, states (iv. 60) that it was also paid by patricians. The usual amount was one for every thousand of a man's fortune, though in the time of Cato it was raised to three in a thousand. Its oppressiveness was caused chiefly by its constant fluctuation.

Trica. In Botany, one of the names of the shield or reproductive organ of a lichen.

Trichechus (Gr. θρίξ, *hair*, and ἰχθύς, *fish*). A name invented by Artedi to designate the manatee, as being the only species of fish, or whale-fish, that was hairy: 'quia solus inter pisces fere hirsutus sit.' Linnæus, in his *System of Nature*, adopted the term *trichechus* as the generic appellation for the manatee (*Trichechus manatus*); but he added the walrus

as a second species of the genus. Subsequent zoologists, in separating these very different animals, and placing them in distinct genera, have in this, as unfortunately in too many other cases, invented a new generic name for the animal so well designated by its original epithet, and have restricted the application of the term *trichechus* to the walrus, for which it was not originally designed.

Trichiasis (Gr. τριχίασις). A disease of the eyelids, in which the eyelashes grow inwards and irritate the bulb of the eye.

Trichidium (Gr. θρίξ). In Botany, a netted filamentous organ resembling a netted purse, in which the spores of some kinds of fungi are included.

Trichilia (Gr. τρίχα, *in three parts*). A genus of *Meliaceæ*, restricted to two or three African, and about a dozen American and West Indian species, some of which are trees, and others erect or climbing shrubs with unequally pinnate or trifoliate leaves and axillary panicles of flowers. *T. emetica*, the Roka of the Arabs, is a large tree, with pinnate leaves, and dense panicles of whitish flowers, like those of the citron. The fruits are said to possess emetic properties. The Arabian women mix them with the perfumes used for washing their hair; while the ripe seeds are made into an ointment with sesamum-oil, and used as a remedy for the itch.

Trichina (Gr. θρίξ, *a hair*). A genus of minute nematoid worms, infesting, in the adult procreative state, the intestinal canal, and, in its larval state, the muscular tissue of man and certain mammals, especially the hog. It is probable that the minute bodies in the muscles of the dropsical drunkard, described by Tiedemann, and analysed by Gmelin as *arthritic concretions* (Froriep's *Notizen*, bd. i. s. 64, 1821), were old calcified cysts of *Trichina*: it is certain that the minute bodies in human muscles, described as *Cysticerci* by Hilton (*Medical Gazette*, February 2, 1833, p. 605), were the adventitious cysts of *Trichina*. The discovery of the worm itself within the cyst, and of the true or adventitious nature of the latter, was made by Owen in 1835, and the worm was described and named by him *Trichina spiralis*, from its common disposition in the cyst, in the *Transactions of the Zoological Society of London*, vol. i. p. 315. Herbst (*Nachrichten von d. G. A. Universität und der K. Gesellschaft d. Wissenschaften*, 1851, No. 19) first showed that the encysted spiral *Trichinæ* were immature, the young of adult *Trichinæ* liberated and fully developed in the intestines of animals which had eaten meat containing encysted *Trichinæ*.

Virchow (*Archiv* 1860) repeated and confirmed Herbst's experiments, and describes the mature *Trichinæ* of both sexes. These acquire the procreative state on the second day after the trichinous meat has been taken into the stomach. About the sixth day the minute filaria-like embryos hatched within the oviducts of the female are excluded. They forthwith penetrate the mucous coat or walls of the intestine, enter the capillaries, are transported by the circulation to the whole muscular system, pierce and escape from the capillaries to penetrate that tissue, and within a fortnight attain the ordinary characters of *Trichina spiralis*, providing themselves by irritation of the sarcolemma with their adventitious cyst, which, at a later period, may become calcified.

As the first introduction of *Trichina* is from eating meat, the animal matter in the garbage or offal commonly given to pigs occasions the frequency of their occurrence in that domestic animal.

Where the custom may prevail of eating pork, or particular forms of pork, e.g. ham, bacon, sausages, &c., imperfectly cooked or raw, the *Trichinæ* in such meat are introduced in a state highly favourable for their developement and procreation into the intestine, and thus is produced the painful and often fatal disease called *Trichiniasis*. The symptoms and cause of this disease are described by Rupprecht, in the notable epidemic degree of the disease, which occurred at Hettstadt, in 1863, and in Dr. Thudicum's excellent report, 'On the Parasitic Diseases of Quadrupeds used for Food.' (No. 7, *Medical Department of the Privy Council*, 1865.) Wholesome feeding of the pig with vegetable food, and thorough cooking of the pork, are the main preventives of *Trichiniasis*.

Trichina Spiralis. [TRICHINA.]

Trichiurus (Gr. θρίξ, and οὐρά, *a tail*). The name of a genus of spiny-finned fishes, literally rendered in their popular English name of *hair tails*, in reference to their most striking generic character, which is taken from the single elongated hair-like filament terminating the rayless tail. The *Trichiuri* have no anal fin, and have neither ventral fins nor supplemental scales. But one species, viz. the silvery hairtail (*Trichiurus lepturus*, Linn.), has been admitted into the catalogue of British fishes.

Trichloracetic Acid. Acetic acid in which three atoms of hydrogen have been replaced by three of chlorine.

Trichlorokinone. A chlorinated derivative of Kinone.

Trichocephalus (Gr. θρίξ, and κεφαλή, *a head*). The name of a genus of Nematoid Entozoons, one species of which (*Trichocephalus dispar*, Rudolphi) infests the human intestinum cæcum.

Trichopterans (Gr. θρίξ, and πτερόν, *a wing*). The name of an order of insects founded by Kirby for the case-worm flies, which are characterised by four hairy membranous wings, resembling in their nervures those of the Lepidopterans; the under ones folding longitudinally.

Trichosanthes (Gr. θρίξ, and ἄνθος, *a flower*). A genus of *Cucurbitaceæ*, consisting chiefly of Asiatic species, which are trailing or climbing plants, with heart-shaped, entire, or lobed leaves, and flowers of separate sexes, usually borne on the same plant. *T. cucumerina*, the Doommaala, a common Cingalese and South Indian plant, is much valued by the native doctors in Ceylon as a remedy for

fevers; and experiments show that it possesses considerable efficacy. It contains tannic acid; and the infusion of it, which is the form used, is very bitter. The Central American *T. colubrina*, the Serpent Cucumber or Viper Gourd, is so called from the remarkable snake-like appearance of its fruits, which are frequently six feet long or more, and at first striped with different shades of green, but ultimately changing to bright orange. *T. anguina*, another long-fruited species, a native of India and China, is called the Snake Gourd.

Triclasite (a word coined from Gr. τρίς, *thrice*, and κλάσις, *cleavage*). A Mineralogical synonym of FAHLUNITE, having reference to its threefold cleavage.

Triclinium (Lat.; Gr. τρίκλινος, *with three couches*). In Ancient Architecture, a room for the entertainment of guests, furnished on three sides with couches, the fourth side being left open for the attendance of the servants. The winter triclinia were placed to the west, and those for summer to the east.

Tricoccæ (Gr. τρίκοκκος, *with three grains*). A name under which Klotzsch and some others have designated the large order *Euphorbiaceæ*, taken in its most enlarged sense.

Tricoccus (Gr. τρίκοκκος). In Botany, a fruit consisting of three cocci, or seeds with elastically dehiscing shells.

Tricolor. The national French banner of three colours, blue, white, and red, adopted on the occasion of the first revolution. The immediate reason for assuming them is said to have been that they were the colours worn by the servants of the duke of Orleans; and they were first borne by the people when the minister Necker was dismissed in 1789. But these colours, in combination, appear to have formed a national emblem in France from a very early period. It is also said to have been formed by uniting the three colours successively used in the French standards at different periods; viz. the blue of the banner of St Martin, the red of the oriflamme [ORIFLAMME], and the white of the white cross, supposed to have been assumed under Philip of Valois. The three colours were given by Henry IV. to the Dutch on their desiring him to confer on them the national colours of his country; and they have since been borne successively by the Dutch republic and the kingdom of the Netherlands. The domestic livery of Louis XIV. was tricoloured, as were also the liveries of the Bourbon kings in Spain. At the revolution, when the three colours were assumed on the national flag, they were borne in the same order as the Dutch, but in a different position, viz. the division of colours parallel to the flagstaff, whereas in the Dutch flag it is at right angles with it. Besides being the favourite banner of the French, tricoloured flags have been adopted in Belgium, Germany, Italy, &c.

Triconodon (Gr. τρεῖς, *three*; κῶνος, *cone*; and ὀδούς, *tooth*). The *Triconodon mordax* was a small carnivorous marsupial animal, of which the crowns of the molar teeth of the lower jaw consisted of three nearly equal cones on the same longitudinal row, the middle one being scarcely larger than the front and hind cone; the coronoid process was larger in proportion to the entire jaw, and afforded a more extensive surface of attachment to the principal biting muscles than in most predatory extinct or recent quadrupeds. It has been found in the Purbeck strata with *Spalacotherium*.

Tricuspid Valve. The valve of the right ventricle of the heart.

Trident (Lat. tridens). The three-pronged sceptre which the poets and painters of antiquity placed in the hand of NEPTUNE is so called by way of eminence.

Triennial Act. The stat. 6 & 7 Wm. & Mary c. 2; providing that a parliament should be held once in three years at least, and that no parliament should last longer than three years. By the Septennial Act (1 Geo. I. sess. 2, c. 38), the duration of parliament was prolonged to seven years.

Triens (Lat.). A small Roman copper coin, worth one-third of the As, as the word implies. This was the piece of money usually placed in the hands of the deceased poor to pay Charon for their passage over the Styx.

Trierarchia (Gr. τριηραρχία). An Athenian institution which imposed on a certain body of citizens the duty of fitting out triremes for the use of the state. About 1,200 citizens were usually chosen for this purpose from the richest individuals, and these were subdivided into clubs of 12 or 16 to each ship. Demosthenes introduced a new regulation, by which the burden to be borne by each individual was made to bear a given proportion to his property. This was effected by making 1,200 of the wealthiest citizens συντελεῖς or partners, and dividing these into twenty Συμμορίαι, or classes, out of which a number of persons joined for the maintenance and management of a ship, under the title of a συντέλεια or union, these synteleiæ consisting generally of 15 persons. [LITURGY.] (Boeckh, *Public Economy of Athens*, ii. 319, 360.)

Trieteris (Gr. τριετηρίς). In Grecian Chronology, a cycle said to have been invented by Thales to correct his year, which consisted of 12 months of 30 days each, amounting to 360 days; as this fell short of the true solar year, he inserted a month of 30 days at the end of every three years, by which means he made it exceed the true year by 13 days.

Triethylamine. A powerful volatile organic base derived from ammonia by replacing the whole of the hydrogen in the latter by ethyl.

Triethylphosphine. An organic base resembling triethylamine, but containing phosphorus in place of nitrogen. It stands to phosphuretted hydrogen in the relation of triethylamine to ammonia.

Trifoliate or **Trifoliolate** (Lat. trifolium, *trefoil*). In Botany, terms applied to leaves which bear three leaflets from the same point, as in those of the clover.

Trifolium (Lat. tres, *three*, and folium, *a leaf*). A genus of papilionaceous *Leguminosæ*, distinguished by their trifoliate leaves, with stipules adhering to the leaf-stalk, and commonly known as Clovers or Trefoils. There are numerous species, several of them natives of Britain, and some of them important from an agricultural point of view. Of these the following may be mentioned: *T. pratense*, the Broad-leaved Red Clover, is extensively employed as a shifting crop, either by itself, or in mixtures which the farmer calls *seeds*. Its arable form is much larger than the wilder varieties, the former being so much an induced plant that it has become difficult to make it hold to some lands so perfectly as it formerly did, in which cases the soil is described as clover sick. *T. medium*, the Zigzag Clover, is a lover of sandy soils, whereas the *T. pratense* is not so well adapted for light land; and being a large species it appears to have been introduced to cultivation as a good cropper where the commoner clover had failed. Its place is now generally supplied by *T. pratense perenne*, commonly called Cow-grass. *T. incarnatum*, the Carnation Clover, is an annual species, much used (especially in the early soils in the neighbourhood of London) upon the white-crop stubble sown in autumn. Several varieties of its seed can be obtained. *T. hybridum*, the Alsike Clover, is much grown on the Continent. It has got the name of *hybrid clover* from its apparently possessing characters intermediate between the common red and Dutch clovers. It is a good pasture plant, its shoots trailing along the ground without rooting, as do those of the Dutch trefoil. *T. repens*, the Dutch clover or shamrock of Ireland, is a valuable feeding plant in dry and thin soils; and in laying down permanent pastures, unless in strong land, it should be always pretty freely employed. Its spontaneous growth in the meadow is always hailed as a sign of an improved condition. A four-leaved shamrock is esteemed by superstitious persons as being lucky, perhaps upon the principle that it is thought to be fortunate to get anything rare; but in truth, four-leaved and even-leaved clovers are not unfrequently met with.

Triforium (Lat.). In Gothic Architecture, an arched story between the pier arches and the clere-story of a building.

Trigamous (Gr. τρεῖς; γάμος, *marriage*). In Botany, a term sometimes applied to plants containing three sorts of flowers in the same flower-head; i.e. males, females, and hermaphrodites.

Trigeminus (Lat.). The fifth pair of nerves; they arise from the side of the pons varolii, where its fibres are prolonged into the middle crura of the cerebellum, and are divided within the cranium into three branches; viz. the *orbital*, and the *superior* and *inferior maxillary*. The orbital branch is divided into the *frontal, lacrymal*, and *nasal nerves*; the inferior maxillary into the *spheno-palatine, posterior alveolar*, and *infraorbital nerves*; and the inferior maxillary into two branches, the *internal lingual*, and one more appropriately termed the *infra-maxillary*. The trigeminal nerve consists of a ganglionic and a non-ganglionic portion.

Trigenic Acid. A crystalline derivative of aldehyd obtained by the action of cyanic acid upon the latter substance.

Trigger (Dan. trekker, Welsh trigaw, akin to Lat. traho, *to draw*). A catch which, being pulled, disengages the hammer of a gun-lock, that it may ignite the percussion arrangement. A hair trigger is one which, when set, will disengage the hammer by the slightest touch, whereas the common trigger requires a pull of some force.

TRIGGER. A small wedge placed under the foot of the dogshore, and suddenly withdrawn at the moment of launching a ship.

Triglyph (Gr. τρίγλυφος, *thrice cloven*). In Architecture, an ornament in the Doric frieze consisting of two whole and two half channels separated by flat spaces called *femora*

Trigonals (Gr. τρίγωνος, *three-cornered*). The name of a family of Decapodous Crustaceans, the carapace of which is nearly triangular.

Trigonella. The most remarkable species of this genus of *Leguminosæ* is that called *T. Fœnum græcum*, the Fenugreek, an erect annual plant, a native of the Mediterranean region, cultivated in India and other warm countries, and occasionally seen in England, though our climate is scarcely suitable to it. The seeds of Fenugreek were held in high repute among the ancient Egyptians, Greeks, and Romans, for medicinal and culinary purposes, but at the present day their use in medicine is with us confined to veterinary practice—Fenugreek powder being the principal ingredient in most of the quack nostrums which find so much favour amongst ignorant grooms and horse-keepers. The seeds have a powerful odour of *coumarine*, and are now largely used for flavouring the so-called concentrated cattle-foods, and for rendering damaged hay palatable.

Trigonia (Gr. τρίγωνος). A name applied by Lamarck to a genus of Ostracean Bivalves, most of the species of which are found fossil, but which has a beautiful representative in the seas of the southern hemisphere, remarkable for the iridescent lining of the valves, *La Trigo nacrée* of Lamarck. It is also the name of a genus of South American plants.

Trigoniaceæ. The genus *Trigonia*, consisting of tropical American trees, with opposite stipulate leaves, and paniculate flowers, presents so many anomalies, that it has been proposed to consider it as a distinct order of polypetalous dicotyledons under the name of *Trigoniaceæ*. It had been referred to *Polygalaceæ*, chiefly on account of its irregular flowers and the long hairs of its seeds; but it has little else in common with the plants of that order, and the position of the petals and insertion of the stamens is quite different.

Trigonocephalus (Gr. τρίγωνος, and κεφαλή, *a head*). A genus of poisonous serpents,

characterised by having the tail terminated by a horny conical process or spur. No species is known to inhabit Europe or Africa, in which continents the *Trigonocephali* are replaced by the vipers. The poisonous serpent of the island of Martinique, called by the French settlers *fer de lance*, is a species of the present genus (*Trigonocephalus lanceolatus*).

Trigonometry (Gr. τρίγωνος; μέτρον, *measure*). This term, as its derivation implies, originally signified the measurement of triangles. In its modern acceptation, however, it denotes that branch of mathematics which treats of angles and of certain ratios connected therewith. Trigonometry is of primary importance in mathematics, and is treated in all text-books: we shall limit ourselves here to a few definitions and formulæ.

Referring to the articles ANGLE and CIRCULAR MEASURE for the methods of estimating the magnitudes of angles, we may proceed at once to the consideration of the four *trigonometrical ratios* or *functions* of an angle known as *sine*, *tangent*, *secant*, and *versed sine*, abbreviations for which are *sin.*, *tan.*, *sec.*, and *versin.*, and to the corresponding functions of the complementary angle, known as *cosine*, *cotangent*, *cosecant*, and *coversed sine*, and usually written *cos.*, *cot.*, *cosec.*, and *coversin*. It would be sufficient to give the *geometrical* definition of one of these eight functions, and define the rest by means of it: we will, however, select two, the *sine* and *cosine*, for this purpose.

The perpendicular divided by the hypothenuse of a right-angled triangle is the *sine* of the angle between the hypothenuse and the base; the base divided by the hypothenuse is the *cosine* of the same angle. By the properties of similar triangles, it is manifest that the ratios thus defined do not depend upon the magnitude of the triangle; in other words, it does not matter from what point of one side (the final line) of an angle we let fall a perpendicular upon the other side (initial line). When the angle is acute, the above definitions of sine and cosine are complete and simple; to extend them to angles of all magnitudes, we notice that, in the language of co-ordinate geometry, the base, perpendicular, and hypothenuse, above mentioned, are, respectively, the *abscissa*, the *ordinate* and the *radius vector* of a point in the final line of the angle. Now, if the radius vector be considered as a *signless* line, whilst the abscissa and ordinate of its extremity follow the ordinary rule of signs [CO-ORDINATES], we have, generally,

$$sine = \frac{ordinate}{rad.\ vector},\quad cosine = \frac{abscissa}{rad.\ vector}.$$

The sine and cosine of an angle are manifestly *periodical functions*, i. e. as the angle increases, the same values recur after every complete rotation. Thus, in the first four quarter rotations, the sines have the signs +, +, −, −, and the cosines the signs +, −, −, +; the first passes through the values 0, 1, 0, −1; the second through the values 1, 0, −1, 0, and all intermediate values. The remaining six trigonometrical functions are defined by the equations—

$$\tan\theta=\frac{\sin\theta}{\cos\theta},\ \sec\theta=\frac{1}{\cos\theta},\ \text{versin}\,\theta=1-\cos\theta,$$

$$\cot\theta=\frac{\cos\theta}{\sin\theta},\ \text{cosec}\,\theta=\frac{1}{\sin\theta},$$

$$\text{coversin}\,\theta=1-\sin\theta,$$

from which their changes of value and sign may be easily traced. The theorem of Pythagoras, in virtue of which $(\text{ordinate})^2+(\text{abscissa})^2=(\text{rad. vector})^2$ leads at once to the formula $\cos^2\theta+\sin^2\theta=1$, which is true for all values of θ, and from which are at once deduced the formulæ—

$$1+\tan^2\theta=\sec^2\theta,\text{ and }1+\cot^2\theta=\text{cosec}^2\theta.$$

Again, the theory of projections leads at once to the *fundamental formulæ*—

$$\sin(\theta+\phi)=\sin\theta\cos\phi+\cos\theta\sin\phi,$$
$$\sin(\theta-\phi)=\sin\theta\cos\phi-\cos\theta\sin\phi,$$
$$\cos(\theta+\phi)=\cos\theta\cos\phi-\sin\theta\sin\phi,$$
$$\cos(\theta-\phi)=\cos\theta\cos\phi+\sin\theta\sin\phi;$$

which are likewise true for all values of θ and ϕ, and from which numerous other formulæ are deducible. Thus we have

$$\tan(\theta\pm\phi)=\frac{\tan\theta\pm\tan\phi}{1\mp\tan\theta\tan\phi},$$
$$\tan 2\theta=\frac{2\tan\theta}{1-\tan^2\theta},$$
$$\sin 2\theta=2\sin\theta\cos\theta,$$
$$\cos 2\theta=\cos^2\theta-\sin^2\theta$$
$$\sin A+\sin B=2\sin\frac{A+B}{2}\cos\frac{A-B}{2}.$$
$$\sin A-\sin B=2\cos\frac{A+B}{2}\sin\frac{A-B}{2}$$
$$\cos A+\cos B=2\cos\frac{A+B}{2}\cos\frac{A-B}{2}$$
$$\cos A-\cos B=-2\sin\frac{A+B}{2}\sin\frac{A-B}{2}.$$

By means of DE MOIVRE'S THEOREM, other important formulæ are deducible. Thus, if n denote any positive integer, the following series will terminate and give the values of the sine and cosine of a multiple angle $n\theta$, in terms of powers of the sine and cosine of the simple angle θ.

$$\sin n\theta=n\cos^{n-1}\theta\sin\theta$$
$$-\frac{n(n-1)(n-2)}{1\,.\,2\,.\,3}\cos^{n-3}\theta\sin^3\theta$$
$$+\frac{n(n-1)(n-2)(n-3)(n-4)}{1\,.\,2\,.\,3\,.\,4\,.\,5}\cos^{n-5}\theta\sin^5\theta-\&c.$$

$$\cos n\theta=\cos^n\theta-\frac{n(n-1)}{1\,.\,2}\cos^{n-2}\theta\sin^2\theta$$
$$+\frac{n(n-1)(n-2)(n-3)}{1\,.\,2\,.\,3\,.\,4}\cos^{n-4}\theta\sin^4\theta-\&c.$$

From these, again, and by aid of an easily demonstrated theorem which shows that $\frac{\sin\theta}{\theta}$,

where θ is the circular measure of a small angle, approaches the limit 1 as θ diminishes without limit, the following series are deduced:—

$$\sin\theta = \theta - \frac{\theta^3}{\lfloor 3} + \frac{\theta^5}{\lfloor 5} - \frac{\theta^7}{\lfloor 7} + \&c.$$

$$\cos\theta = 1 - \frac{\theta^2}{\lfloor 2} + \frac{\theta^4}{\lfloor 4} - \frac{\theta^6}{\lfloor 6} + \&c.$$

and these, when compared with the Exponential Theorem, lead to the important and remarkable relations:—

$$\sin\theta = \frac{e^{\theta\sqrt{-1}} - e^{-\theta\sqrt{-1}}}{2\sqrt{-1}}$$

$$\cos\theta = \frac{e^{\theta\sqrt{-1}} + e^{\theta\sqrt{-1}}}{2}.$$

With respect to the primary problem of trigonometry, the *solution of plane triangles* or the determination of three unknown elements (sides or angles) from three known ones, we remark merely that the definitions of the trigonometrical functions lead at once to the solution of all cases of right-angled triangles, whenever, by means of *trigonometrical tables*, the angles corresponding to given values of trigonometrical functions, and, conversely, the values of the several trigonometrical functions corresponding to given angles, can be found.

The several cases of oblique-angled triangles are easily solved by means of the following relations: If a, b, c, represent the sides of a triangle respectively opposite to the angles A, B, C, and for brevity we put $2s = a + b + c$, then $\frac{\sin\theta}{a} = \frac{\sin B}{b} = \frac{\sin C}{c} = \frac{2\,\Delta}{a\,b\,c}$; where Δ, the *area of the triangle*, has the value

$$\Delta = \sqrt{s\,(s-a)\,(s-b)\,(s-c)}.$$

When two sides a, b, and the included angle C are given, the third side may be found by the formula $c^2 = a^2 + b^2 - 2\,a\,b\cos C$, immediately deducible from Euclid ii. 12, 13. The angles A and B may be found, without calculating c, from the formula—

$$\frac{\sin A - \sin B}{\sin A + \sin B} = \frac{a-b}{a+b} = \frac{\tan\frac{A-B}{2}}{\tan\frac{A+B}{2}},$$

since $\frac{A+B}{2} = \frac{\pi - C}{2}$ is known. When two sides a, b, and a *non-included* angle B are given, the formula $\sin A = \frac{a}{b}\sin B$ will lead at once to the discovery of A, provided we know that A is less than B, which will be the case if a is less than b. If a be greater than b, however, then since an angle and its supplement have the same sine, we cannot decide which to select of the two angles given by the above formula for A. This is the so-called *ambiguous case*. [Triangle.]

We proceed with equal brevity to notice *Spherical Trigonometry*, or that branch of trigonometry which treats of the relations existing between the sides and angles of spherical triangles. Referring to the article Spherics for the necessary definitions, we may remark that all spherical trigonometry is comprehended in the formula—

$$\cos a = \cos b\cos c + \sin b\sin c\cos A,$$

where a, b, c represent the *sides* of the triangle, i. e. the *angles* subtended at the centre of the sphere by the arcs of great circles which form the sides, and A, B, C, the *angles* respectively opposite to a, b, c. It is obvious that in the above formula, as in all the following, we may obtain others by mere permutations of letters. Introducing the symbol s to denote half the sum of the sides, we readily deduce from the above formula the following two:—

$$\sin^2\frac{A}{2} = \frac{\sin(s-b)\sin(s-c)}{\sin b\sin c},$$

$$\cos^2\frac{A}{2} = \frac{\sin s\sin(s-a)}{\sin b\sin c};$$

whence, by division, we obtain the value of $\tan\frac{A}{2}$, and by multiplication the following:—

$$\frac{\sin A}{\sin a} = \frac{2\,\{\sin s\sin(s-a)\sin(s-b)\sin(s-c)\}^{\frac{1}{2}}}{\sin a\sin b\sin c}$$

From the symmetry of the expression on the right, we at once conclude that

$$\frac{\sin A}{\sin a} = \frac{\sin B}{\sin b} = \frac{\sin C}{\sin c};$$

an important theorem, which may be readily established directly. The combination of the last with the first formula leads at once to the following, from which five others may be deduced by mere permutations of letters:—

$$\cot a\sin b = \cot A\sin C + \cos b\cos C.$$

In virtue of the properties of Supplemental Triangles, we may deduce from the foregoing as many new formulæ, by replacing a, b, c, A, B, C, by $\pi - A$, $\pi - B$, $\pi - C$, $\pi - a$, $\pi - b$, $\pi - c$, respectively. To the above, we will add the following, which, with their supplemental formulæ, are known as *Napier's Analogies*:—

$$\left.\begin{aligned} \tan\tfrac{1}{2}(A+B) &= \frac{\cos\frac{1}{2}(a-b)}{\cos\frac{1}{2}(a+b)}\cot\frac{C}{2} \\ \tan\tfrac{1}{2}(A-B) &= \frac{\sin\frac{1}{2}(a-b)}{\sin\frac{1}{2}(a+b)}\cot\frac{C}{2}, \end{aligned}\right\}$$

and the following four, which are known as *Gauss's Theorems*, although discovered by Delambre:—

$$\left.\begin{aligned} \cos\tfrac{1}{2}(A+B)\cos\tfrac{1}{2}c &= \cos\tfrac{1}{2}(a+b)\sin\tfrac{1}{2}C \\ \cos\tfrac{1}{2}(A-B)\sin\tfrac{1}{2}c &= \sin\tfrac{1}{2}(a+b)\sin\tfrac{1}{2}C \\ \sin\tfrac{1}{2}(A+B)\cos\tfrac{1}{2}c &= \cos\tfrac{1}{2}(a-b)\cos\tfrac{1}{2}C \\ \sin\tfrac{1}{2}(A-B)\sin\tfrac{1}{2}c &= \sin\tfrac{1}{2}(a-b)\cos\tfrac{1}{2}C \end{aligned}\right\}$$

The above formulæ serve to solve all possible cases of spherical triangles, where, three elements being given, it is required to determine the remaining three.

By putting one of the angles equal to 90°, we obtain the six formulæ for the solution of

right-angled triangles; all of which, however, may be easily written down by means of *Napier's rules of circular parts*. [CIRCULAR PARTS.] From the supplemental formulæ, which we have not thought it necessary to give, the six corresponding formulæ for the solution of quadrantal triangles are deduced by making a, b, or c, equal to 90°. With respect to the superficial area of a spherical triangle, see SPHERICS and SPHERICAL EXCESS.

Trigonous (Lat. trigonus, Gr. τρίγωνος, *three-cornered*). In Botany, this term is applied to bodies having three angles and three plane faces, as the stems of *Carices*.

Trilateral (Lat. trilaterus, from latus, lateris, *a side*). Three-sided; a term applied to all triangular figures.

Trilinear Co-ordinates. [CO-ORDINATES.]

Trilliaceæ (Trillium, one of the genera). A small order of Endogens, distinguished by their simple stems, bearing a whorl of netted-veined leaves, and a single terminal flower, usually with three herbaceous sepals, three larger petals, six to ten stamens with linear anthers, a free ovary with three to five cells and as many distinct styles, and a succulent fruit. The species are all natives of the temperate regions of the northern hemisphere, and are distributed into five or six genera. The fleshy roots of *Trillium erectum*, under the name of Beth-root, form one of the numerous drugs prepared for sale in the United States by some of the societies of the religious sect called *Shakers*. They are esteemed astringent, tonic, and antiseptic, and are employed in spitting of blood and several other complaints. The plant is also called *Indian Balm* or *Lamb's Quarters*. It has an erect stem a foot or more high, bearing three broad almost rhomboid leaves, and drooping fetid flowers, with green sepals striped with purple, and deep purple petals.

Trillion. In Arithmetic, a million of billions, or a million of million of millions. The term is said by Dr. Johnson to have been invented by Locke.

Trillo (Ital.). In Music, a SHAKE. It is abbreviated *tr*.

Trilobites (Gr. τρίλοβος, *three-lobed*). The name given by Cuvier to an order of Crustaceans, comprehending those remarkable fossil species in which the body is divided into three lobes by two fissures which run parallel to its axis.

Trilogy (Gr. τριλογία). This word is applied to a series of three dramas, which, although each of them is in one sense complete, yet bear a mutual relation, and form parts of one historical and poetical picture. The *Agamemnon*, *Choephoræ*, and *Eumenides* of Æschylus, and the *Henry IV.* of Shakspeare, are examples of a *trilogy*.

Trim (A.-Sax. trum). The position of the keel of a ship with respect to a horizontal line. Also the disposition of the weights or stowage, as favourable or otherwise for sailing, which are expressed by *in trim* and *out of trim*.

Trimerans (Gr. τριμερής, *tripartite*). The name of a section of Coleopterous insects, including those which have each tarsus composed of three articulations.

Trimethylamine. An organic base resembling triethylamine, but containing the radical methyl instead of ethyl.

Trimmer. In Architecture, a piece of timber framed at right angles to the joists opposite chimneys or the well-holes of stairs; it receives the ends of the joists intercepted by the opening.

Trimming Joist. In Architecture, a joist into which a trimmer is framed.

Trimyaries (Gr. τρεῖς, and μυών, *a muscle*). The name by which those Bivalves are distinguished which present three muscular impressions on each valve.

Trinacrite. A micaceous mineral of a dull-brown colour from Sicily (the ancient Trinacria).

Trine (Lat. trini, the distributive of tres, *three*). Of threefold dimensions—length, breadth, and thickness. In Astrology, the trine was one of the five aspects (a benign one) of the influential bodies. [ASTROLOGY.]

Tringa. A genus of wading birds (*Grallæ*), characterised by a compressed bill of moderate length, enlarged at the point, and a hind toe, too short to reach the ground. It is by the latter character that the lapwings (*Tringæ*) are distinguished from the plovers (*Charadrii*), in which the hind toe is wanting.

Trinitarians. A general name for those who believe in the TRINITY.

The word also denotes a religious order, founded in 1198 under the pontificate of Innocent III. Its members devoted themselves especially to the duty of ransoming captives taken by the Moors and other infidels. Another body of Trinitarians was formed in consequence of a reformation of the order in 1578. There was also an order of the same name for women, dedicated to the same objects.

Trinity (Lat. Trinitas). A name employed to denote the three Persons comprised in the Godhead, and distinguished as the Father, the Son, and the Holy Ghost. The term is not found in the books of the New Testament, and its introduction is referred at the earliest to the second century. [THEOLOGY.]

Trinity House. The Trinity House was incorporated by Henry VIII. in 1515, for the promotion of commerce and navigation, by licensing and regulating pilots, and ordering and erecting beacons, lighthouses, buoys, &c. The corporation is governed by a master, wardens, assistants, and elder brethren. Its privileges and powers were confirmed by a charter of James II., and have been extended and defined by the Merchant Shipping Act of 1854.

Trinity Sunday. The Sunday next after Whit Sunday; so called on account of a feast which was held anciently, and still continues to

be held, on that day in honour of the Holy Trinity. This feast does not appear to have been fully established in the Western Church until the year 1334, under Pope John XXIII.

Trinoda Necessitas. [BOCLAND.]

Trinomial (Lat. tres, *three*, and nomen, *name*). In Algebra, a quantity consisting of three terms connected by the signs + or −; as $a^2 + bc^2 - d^3$.

Trinragan. An Eastern name of the Palmyra Palm.

Trio (Ital.). In Music, a composition consisting of three parts.

Tricecious (Gr. τρεῖς, *three*, and οἶκος, *a house*). In Botany, a term applied to designate those plants which have male flowers on one individual, female on another, and hermaphrodite on a third.

Triolet. A stanza of eight lines, in which the first line is thrice repeated.

Triones (Lat.). In Astronomy, the seven principal stars in the constellation Ursa Major, popularly called Charles's Wain; four of the stars being fancied to represent a wain or waggon, and the three others the oxen by which it is drawn. [RISHIS, THE SEVEN.]

Trioxide or **Teroxide.** In Chemistry, such oxides as contain one atom of element united to three atoms of oxygen.

Tripe (Fr.; Ital. trippa, Span. tripa). The first and second stomachs of ruminants, when properly prepared, constitute *tripe*.

Tripe de Roche (Fr.). A name given in North America, from their blistered thallus, to several species of *Gyrophora* and *Umbilicaria*, especially the latter, which afford a coarse food, whose nutritive qualities are, however, much impaired by the presence of a bitter principle which is apt to cause serious diarrhœa. Bad, however, as rock tripe is, it has done good service to some of our arctic voyagers, especially to the expeditions under the lamented Sir John Franklin. In no case, however, did it completely appease the pangs of hunger, probably from its not containing in the proper proportions all the constituents which are necessary to compose a truly nutritious article of food. Some of these lichens, of large size, have been found on the farthest northern land which has yet been explored.

Tripe-stone. The name given to a particular form of Anhydrite from Wieliczka and Bochnia in Poland, which bears a sort of outward resemblance to the convolutions of the intestines.

Triphane (Gr. τριφανής, *appearing threefold*). A Mineralogical synonym of Spodumene.

Triphthong (Gr. τρεῖς, and φθογγός, *a voice*). In Grammar, a composite sound of three vowels, as a diphthong is of two; such as the German *aeu*. There is no such sound in English, nor, strictly speaking, in French, unless the combinations *ieu* in that language be so considered.

Triphyline (Gr. τρεῖς, and φυλή, *a clan*). A triple phosphate of lithia, manganese, and iron, found commonly in coarsely granular crystalline masses of a greenish-grey colour, at Rabenstein in Bavaria.

Triphyllous (Gr. τρίφυλλος, *three-leafed*). In Botany, a term applied to those plants which have their leaves in whorls of three, or to those which produce only three leaves.

Triple (Lat. triplex). In Music, one of the kinds or measures of time, of which there are many different subdivisions. There are, however, only four principal ones, of which the others are varieties. [MUSIC.]

Triple Phosphate. The phosphate of ammonia and magnesia (MgO, NH_4O, HO, PO_5), which sometimes forms urinary calculi.

Triple Tangent Line of a Surface. A right line which touches the surface three times, or which meets it in three pairs of coincident points. To be so touched, the order of the surface must exceed the fifth, and when it does so there will in general be an infinite number of triple tangent lines, situated on a ruled surface, since a line in space requires four conditions for its complete determination. According to Dr. Salmon (*An. Geom. of Three Dimensions*), the points of contact of triple tangent lines are on the intersection of the given surface of the n^{th} order with one whose order is—

$$\tfrac{1}{2}(n-2)(n-4)(n-5)(n^2+5n+12).$$

If of the three points of contact of a triple tangent line two coincide, it will become an inflexional tangent which touches the surface elsewhere. Triple tangent lines of this kind lie on a surface of the order—

$$n(n-3)(n-4)(n^2+6n+4),$$

and the points of contact at which the lines are inflexional tangents lie on a surface of the order $(n-4)(3n^2+5n-24)$, whilst the points at which the lines in question are simple tangents lie on a surface of the order—

$$(n-2)(n-4)(n^2+2n+12).$$

When all three points of contact coincide, the triple tangent line becomes what Dr. Salmon terms a *double inflexional tangent*, since, meeting the surface in four consecutive points, it may be regarded as an inflexional tangent at two of them. The locus of the points of contact of such tangent lines is the intersection of the original surface with another of the order $11n-24$, possessing interesting properties, and the lines themselves generate a surface of the order $2n(n-3)(3n-2)$.

Triple Tangent Plane of a Surface. A plane which touches the latter at three distinct points. According to Salmon, the number of such planes, for a surface of the n^{th} order, is—

$$n(n-2)(n^7-4n^6+7n^5-45n^4+114n^3-111n^2 + 548n-960).$$

Triplets. In Poetry, three verses rhyming together.

In Music, notes grouped together by threes; thus, . In common time, where

three of the quavers are intended to be equal in duration to a crotchet, a 3 is sometimes placed over them; but they are generally known by being grouped together, and thus form one of the single parts of the whole measure.

Triplicate Ratio. The triplicate ratio of two numbers or magnitudes is the same as the ratio of the first to their fourth proportional. It is equal to the cube of their ratio, or the ratio of their cubes, in the case of numbers.

Triplite (a word coined from Gr. τρεῖς, and λίθος, *stone*). A mineral composed of phosphoric acid in combination with the protoxides of iron and manganese, which occurs of a pitch-black to a clove-brown colour, in compact crystalline masses with a lamellar structure, and a cleavage in three directions at right angles to each other, near Limoges in France, in a quartz-vein traversing granite; also at Peilau in Saxony.

Tripod (Gr. τρεῖς, *three*, and πούς, *a foot*). In Architecture, a vessel, table, seat, or instrument having three feet. It was from such a seat that the Pythian goddess rendered oracular answers at Delphi.

Tripoli. The name of a powder greatly used in polishing metals, stones, &c., and consisting almost exclusively of the silicious portion of the cases of infusorial animalcules and *Diatomaceæ*, divested of everything except the silex. It was first imported from Tripoli, whence its name. Many other localities are now known in which the same material is found. Ehrenberg estimated that forty thousand millions of individuals of *Gaillonella distans* were contained in each cubic inch of the tripoli from Bilin, a well-known locality in Bohemia, where there is a deposit of it fourteen feet thick extending over a wide area.

Several of the species of which this powder is composed are found to be identical with those which are at the present day contributing to form a sediment on the Victoria Barrier, in the Antarctic regions, hundreds of miles in length. The Phonolite stones of the Rhine also abound in the remains of *Diatomaceæ*.

Triptolemæa. A group of Brazilian *Leguminosæ*, now by the best authorities united with *Dalbergia*, an extensive genus common to the tropics of both hemispheres. The *Triptolemæas* are trees or woody climbers, with alternate pinnate leaves. The Rosewood of commerce, imported from Brazil, was for a long time supposed to be yielded by this genus upon the authority of the French traveller and botanist Guillemin, who brought from Brazil specimens of two species of *Triptolemæa* as the true rosewood plant; but, according to Dr. Allemão of Rio Janeiro, the greater part of the best kind of rosewood sent to Europe is the wood of *Dalbergia nigra*, while other qualities are the produce of species of *Machærium*. [ROSEWOOD.]

Triptolemus (Gr. Τριπτόλεμος). Many parents are assigned to this hero of Greek Mythology, who, according to Apollodorus, is a son of Keleos, king of Eleusis, in whose house Dêmêtêr rested during her woeful pilgrimage in search of PERSEPHONÊ. To requite the kindness of the daughters of Keleos, Dêmêtêr wished to render Demophon, the infant brother of Triptolemus, immortal. She therefore plunged the child by night into a fire; but his mother, Metaneira, discovering what Dêmêtêr was doing, screamed out, and the babe was consumed by the fire, while Dêmêtêr revealed herself in her true character, and gave to Triptolemus a chariot, drawn by winged dragons, and corn with which he sowed the whole earth, thus providing bread for the children of men. This dragon-chariot is manifestly the same as the chariots of Medeia and of Helios, drawn by winged beings, who are the Harits or the CHARITES.

By Hyginus, Triptolemus is represented as a son of Eleusis, and as being the child whom Dêmêtêr wished to render immortal. In this version Eleusis, and not his mother, discovers the secret deed of Dêmêtêr, and is by her immediately put to death.

In the Athenian Mythology, Triptolemus instituted the feast called *Thesmophoria* in honour of the goddess, and was the great hero in the Eleusinian mysteries, the plough and agriculture being regarded as his special gifts to men.

Triptote (Gr. τρίπτωτος). In Grammar, a noun that has only three cases.

Trireme (Lat. triremis, Gr. τριήρης, *a galley with three rows of oars*). The usual war vessel of the Greeks at the time of the Persian and Peloponnesian wars. [GALLEY; PENTECONTORI; QUINQUEREMIS.]

Some light has been thrown on Athenian naval matters by the discovery of some inscriptions at the Piræeus, which have been commented on by Boeckh. (*Public Economy of Athens*, transl. i. 372 &c.)

Trisagion (Gr. τρισάγιος, *thrice holy*). In the Greek Church, the threefold invocation of the Deity as 'Holy' (Lat. tersanctus). This invocation takes its origin from Isa. vi. 3, Rev. iv. 8. The ordinary form is that in Isaiah, 'Holy, holy, holy, Lord God of hosts, all the earth is full of Thy glory.' A different form of the trisagion is repeated daily in the service of the Greek church, and is attributed to Saint Proclus.

Trisection of an Angle. A Geometrical problem of great celebrity among the ancient Greek mathematicians. The indefinite trisection of an angle cannot be effected by plane geometry, i.e. by means of the straight line and circle, inasmuch as the analytical equation on which it depends rises to the third degree; but it may be accomplished by means of the conic sections and some other curves. [QUADRATRIX.]

Pappus of Alexandria, in the fourth book of his *Mathematical Collections*, reduces the problem to that of drawing a line through a given point so that the intercept upon it made by two given lines, at right angles to each other, shall be double the distance of the intersection of these lines from the given point. He also

shows how this problem may be solved by means of a hyperbola.

Trismus (Gr. τρισμός). Lockjaw; tetanus affecting the jaw.

Trispast or **Trispaston** (Gr. τρίσπαστος, *drawn threefold*). A machine with three pulleys acting in connection with each other for raising heavy weights.

Tritheism (Gr. τρεῖς, and Θεός). In controversial theology, the name applied to an opinion which is the reverse of SABELLIANISM.

Trithionic Acid. An unstable acid of sulphur, produced by heating a solution of sulphite of potash with sulphur.

Triticum (Lat.). A genus of grasses, including, with the Common Wheat, the equally common Creeping Couch, one of the most troublesome weeds of the farm. *T. vulgare* is an annual cereal or corn grass, which under the name of Wheat is well known to everyone, but its native country and origin have ever been curious subjects of speculation. M. Fabre's experiments afford very strong reason to conclude that this cereal is derived from a wild grass of Southern Europe and Western Asia, known to the botanist as *Ægilops*. Though at first sight appearing to be very different from wheat, it is really not so on a minute examination of its parts, and indeed in cultivation soon affords a very respectable grain; its green herbage, too, emits on being bruised the peculiar smell which belongs to wheat, and like wheat it is subject to the same epiphytes or attacks of *blight*. That a plant very dissimilar from wheat, in fact a wild useless grass, should yet in cultivation become so changed as to afford a useful grain, leads us to expect, from this amount of adaptability to circumstance, that it would be capable of easily affording a large variety of sorts. Such we know to be the case, and hence few plants are so easily adapted to every climate, soil, and management as wheat.

T. repens, the Couch, is far too well and unfavourably known. *T. caninum* differs from it mainly in the absence of the running underground stems (rhizomes). It has, however, the same pungent flavour which belongs to all the *Tritici*, due probably to the presence of some kind of essential oil, in virtue of which it would appear to be capable of exerting powerful emetic action, at least on dogs. [WHEAT.]

Tritogeneia. [MINERVA.]

Tritomite (Gr. τρίτομος, *thrice-cut*). A hydrous mineral related both in form and composition to Helvine and Garnet. It is found in the syenite of the island Lamö in Norway.

Triton (Gr.). In the Homeric Mythology, a son of Poseidon and Amphitritê; but Tritons are sometimes mentioned in the plural. The word recurs in the Vedic Tritæ [THRAÊTANA], as well as in the Greek Tritogeneia, Tritopatreus, &c. [MINERVA.]

TRITON. In Zoology, the name *Tritonia* has been given to a genus of marine, naked, gastropodous Molluscs, or sea-slugs.

Tritone (Gr. τρίτονος, *of three tones*). In Music, an interval, now generally called a *sharp fourth*, consisting of four degrees, and containing three whole tones between the extremes, on which account the ancients gave it its name. It is moreover divisible into six semitones, three diatonic and three chromatic.

Tritopatreus. A son of Zeus and Persephonê, and one of the Dioscuri. [POLYDEUKÊS; TRITON.]

Trityl. [PROPYL.]

Triumph (Lat. triumphus, Gr. θρίαμβος). The highest military honour that could be obtained by a Roman general. It was a solemn procession, with which the victorious leader and his army advanced through the city of Rome to the Capitol, accompanied by the captives taken in war, and vehicles bearing the spoils and all the furniture that could add magnificence to the spectacle. On arriving at the Capitol, the general offered up a prayer of thanksgiving to Jupiter and the other gods, and sacrificed white bulls. A triumph was decreed by the senate, and sometimes by the people against the will of the senate, to the general who in a just war with foreigners, and in one battle, had slain above 5,000 enemies of the state, and enlarged the limits of the empire. [OVATION.]

Triumphal Arch. In Architecture, an arch erected to perpetuate the memory of a conqueror, or of some remarkable victory or important event. At first it consisted of a single arch, decorated merely with a statue and spoils of the victorious commander; but arches were afterwards erected with two, and then with three, passages.

Triumvirate. In Ancient History, this term was applied to two great coalitions of the three most powerful individuals in the Roman empire for the time being. The first of these was effected in the year 60 B.C. between Julius Cæsar, Pompey, and Crassus, who pledged themselves to support each other with all their influence. (For a defence of this alliance on the ground of public spirit, see the remarks of Napoleon III. in his *Life of Cæsar*, book ii. ch. iv.) This coalition was broken by the fall of Crassus at Carrhæ in Mesopotamia; soon after which the civil war broke out, which ended in the death of Pompey, and establishment of Julius Cæsar as perpetual dictator. After his murder, 44 B.C., the civil war again broke out between Antony, who wished to avenge the death and succeed to the fortunes of Cæsar, and the republic, on whose side were ranged Octavius and Brutus. Lepidus with a large army remained in suspense which side to take. But after the battle of Mutina, in which both consuls fell, 43 B.C., Antony, Octavius, and Lepidus coalesced; thus forming the second triumvirate, each party confirming the bond of union by the sacrifice of some of his own friends to the hatred of the others; among these was Cicero, who was delivered up by Octavius to the vengeance of Antony. Against

this confederation Brutus still held out with the rest of the conspirators who had overthrown Cæsar, till their destruction at the battle of Philippi. The triumvirs then divided the provinces of the empire, Octavius taking the west, Lepidus Italy, and Antony the east; but the union was soon broken by the passion of Antony for Cleopatra, which induced him to repudiate Octavia, the sister of Octavius. War ensued, which was terminated by the defeat and death of Antony at Actium, in 32 B.C.; after which everything fell into the hands of Octavius, Lepidus offering no obstacle.

Triuridaceæ (Triuris, one of the genera). A small order of Endogens, consisting of slender colourless herbs, often almost transparent, without any other leaves than small scales, and small flowers either solitary or in terminal racemes. In their usually six-parted perianth, hypogynous stamens, distinct carpels, and apparently homogeneous embryo, they are connected with *Alismaceæ*, from which they differ chiefly in the divisions of the perianth being always valvate in a single series, and in their embryo not being curved. These curious little plants are generally found, like the smaller *Burmanniaceæ*, on rotten leaves or other decaying vegetable matter in the moist tropical forests of both the New and the Old World.

Trivium (Lat trivius, *of three ways*). The name given in the schools of the middle ages to the first three liberal arts (grammar, rhetoric, and logic), which were studied together. The other four (arithmetic, music, geometry, and astronomy) formed what was termed the *quadrivium*: and the two following mnemonic lines comprehend the whole:—

> Gram. loquitur; Dia. verba docet; Rhe. verba ministrat;
> Mus. canit; Ar. numerat; Ge. ponderat; As. colit astra.

Trocar. An instrument used in tapping for the dropsy. The name is said to be corrupted from the French *trois-quarts*, from the three sides of its point.

Trochanter (Gr. τροχαντήρ, *a runner*; because the muscles inserted into it are those chiefly concerned in the act of running). A name given to two processes (greater and less trochanter) at the upper end of the thigh bone. In the odd-toed (perissodactyle) Mammalia, a large process is developed in the middle of the thigh bone, to which the term *median trochanter* is applied.

Troche (Gr. τροχός, *a wheel*, from τρέχω, *I run*). A small round lozenge or cake, generally composed of sugar and mucilage, united with small portions of more active remedies, intended to be allowed gradually to dissolve in the mouth.

Trochee (Gr. ὁ τροχαῖος, sc. πούς). A rhythmical measure consisting of two syllables, a long and a short; thus, – ⏑.

Trochilus (Gr. τροχίλος). The trochilus, according to Herodotus, was a bird which plucked βδέλλαι (*leeches*; he should have said *flies*) out of the crocodile's mouth. By Pliny the name seems to have been applied to the wren. Linnæus uses the word to denote the genus of small and brilliantly coloured birds which, from the energy and rapidity of the vibrations of their wings during flight, are called *humming-birds*. This genus includes the smallest of the feathered tribe, and, if we except a few fishes, the most diminutive of vertebrated animals. Some humming-birds scarcely exceed a humble-bee in size; they are unable to escape from the strong webs of the large spiders of the American tropics, and thus sometimes become their prey.

The humming-birds are characterised by a long and slender bill, enclosing an extensile bifid tongue, by which they extract the nectar and the small insects which may lurk in the recesses of flowers. They have very small feet, long and narrow wings, a broad and entire sternum with an unusually deep keel, and a short and strong humerus; all combining to form a mechanism for rapid and powerful flight, like that of the swift. Humming-birds live in pairs: they have the character of being very quarrelsome, the males fighting desperately with each other: both sexes combine to defend their nests with courage.

Trochlea (Lat.; Gr. τροχαλία). In Anatomy, this term is applied to the cartilage through which the tendon of the *trochlearis muscle* passes. It is the superior oblique muscle of the eyeball, and is accompanied by the *trochlearis nerve*.

TROCHLEA. In Mechanics, the same as *pulley* or *tackle*. [PULLEY.]

Trochoid (Gr. τροχοειδής, *like a wheel*). The curve described by a point on the radius of a circle when the latter rolls on a right line. The trochoid becomes a CYCLOID when the describing point is at the extremity of the radius, i.e. on the circumference of the rolling circle.

Trochus (Gr. τροχός). The name given by Linnæus to a genus of the *Vermes Testacea*, characterised by a subconical spiral shell, with the margin entire, without a fissure or canal for the siphon of the mantle, the animal not possessing any respiratory tube. The mouth of the shell is closed by an operculum, or some analogous part. The species to which the characters of the Linnæan genus are applicable constitute a family of Pectinibranchiate Gastropods in the system of Woodward, called *Trochidæ*, which includes the following genera: *Turbo*, *Phasianella*, *Imperator*, *Trochus Elenchus*, *Rotella monodonta*, *Delphinula*, *Cyclostrema*, *Euomphalus*, *Ophileta*, *Phanerotinus*, *Stomatella Gena*, *Broderipia*. The Gastropod called *Turbo pica* by Linnæus, having been ascertained to have an operculum, is now referred to the genus *Trochus*.

Troglodytes (Gr. τρωγλοδύτης, from τρώγλη, *cave*, and δύω, *I enter*). Tribes of men who have their dwellings in subterraneous caverns. Several such tribes are mentioned by ancient authors, and the remains of their dwellings still attest their existence, especially along the banks of the Nile, in

Upper Egypt and Nubia, and in parts of Syria and Arabia.

The chimpanzee has been called by Blumenbach *Simia Troglodytes*.

Trolls. In Teutonic Mythology, a race of beings engaged in a perpetual struggle with men, just as the Frost Giants of Utgard, the outer world, waged a continual war with the Æsir who dwelt on Asgard, a lofty hill in the centre of Mitgard, the habitable world (answering to Delos, as the γῆς ὀμφαλός of the Greeks). These Trolls are superior to man in strength and stature, but far beneath him in mind. In short, they are always outwitted, just as the Greek Titans are overcome by Zeus when aided by Prometheus, the forethinker. The Trolls thus embody the idea of unintellectual brute force, or mere awkward strength; it must, however, be remembered that the Trolls are not the only beings who, formidable in some respects, are still defeated by man. The idea of a devil has been traced to Iranian DUALISM. Although this idea seems to be absent from the prophetical books of the Old Testament, it was fully developed before the Christian era; and thus it was disseminated among the nations of Northern as of Southern Europe. In the mind of the former the notion seems to have found at first no congenial soil; and thus the Teutonic devil is exhibited for the most part as an unprincipled simpleton, who is constantly brought into ludicrous or contemptible positions. This stupidity in the Trolls has by some been accounted for on the ground that they represent the old aboriginal races who retired into the mountainous fastnesses of the land, and whose strength was exaggerated because the intercourse between the races was small. (Dasent, *Popular Tales from the Norse*, lviii.) If we cannot in terms deny, we have no evidence to warrant us in upholding this euêmeristic interpretation. It may, however, be remarked that the Northern mythology, like that of the Greeks, peopled every spot of earth, seas, mountains, lakes, stream, trees, woods, with its own superhuman inhabitants; that the systems of both were coloured in accordance with the conditions of soil and climate in their respective countries; and that the characteristics of the Æsir, the Frost Giants, the Trolls in the one case, and of the Olympian gods, the Titans, the Giants in the other, seem to be fully accounted for by the physical differences which distinguish Northern Europe from the countries on the Mediterranean Sea.

Trombolite. [THROMBOLITE.]

Trombone (Ital.). A brass musical wind instrument, somewhat similar in form to the trumpet, but larger, and made with a slide, by means of which the intonation can be regulated, and the complete scale played. There are three sizes of trombones, playing alto, tenor, and bass respectively; these are also used with much effect in the modern orchestra.

Tron Weight. The most ancient of the weights used in Scotland; and though its use is now prohibited by law, it is still occasionally employed in some of the rural districts in weighing wool, cheese, butter, &c. The tron pound was not a well-defined weight, but varied from 21 to 28 ounces avoirdupois.

Trona. Native sesquicarbonate of soda; composed, when pure, of 37·8 per cent. of soda, 40·2 carbonic acid, and 22 water. It is found for about ten miles along the coast east of Aden, Suckena in Africa, Barbary, Columbia [URAO], South America, &c., generally in fibrous masses composed of a congeries of minute white crystals, inclining to yellowish-grey when impure.

Troop (Fr. troupe; Ger. trupp; probably akin to Lat. turba, Gr. τύρβη). In cavalry, the unit for discipline, corresponding to *company* in the infantry. Each troop on home service at present consists of three officers, five sergeants, and sixty-three rank and file.

Troostite. A variety of Willemite containing 2 per cent. of carbonate of protoxide of manganese; and named after Dr. Troost, of Nashville College, Tennessee. It is a ferruginous silicate of manganese, and is found at Stirling in New Jersey.

Tropæolaceæ. An order established for the genus *Tropæolum*, which, formerly placed in *Geraniaceæ*, has been repeatedly separated from it, but is again reunited, especially on account of the close affinity which the structure of its flowers exhibits to that of *Pelargonium*.

Tropæolum (Lat. tropæum; Gr. τρόπαιον, *a trophy*). An extensive genus of herbs, representing the group (or order) *Tropæolaceæ*, and consisting of climbing plants, all South American, many of them in cultivation, and of an ornamental character. The *Tropæolums* are remarkable for possessing an acrid taste, similar to that which exists among the *Cruciferæ*; and two of the species are grown for culinary purposes, *T. majus* and *T. minus*.

T. majus, the Indian Cress or Nasturtium, is a hardy annual, native of Peru, of trailing habit, but which, when its succulent stems can obtain any bush for support, will attach itself by means of the long twining petioles, and attain a considerable height. The flowers are large and showy, and the seeds consist of three conjoined berries or nuts, with grooved wrinkled gibbous husks, which become fungous when dry. The flowers and young leaves are frequently used to mix in salads. They have a warm taste, not unlike that of the common cress, from which circumstance the plant has obtained the name of Nasturtium. The berries are gathered when young and quite green, and make, without the aid of spice, an agreeable pickle, which, as well as the green leaves steeped in vinegar, is accounted a good antiscorbutic, and also forms an excellent substitute for capers. *T. minus* is very similar in appearance to *T. majus*, but is smaller in every respect, and of dwarf weak growth. The seed-pods are also small, on which account they are considered preferable to those of *T. majus* for pickling as a substitute for capers.

Trope (Gr. τρόπος, from τρέπω, *I turn*). In Rhetoric, literally any expression *turned* from

its primary signification, and employed in a sense derived in some manner from that primary signification. In this sense, the general term *trope* comprises the various figures termed ALLEGORY, METAPHOR, METONYMY, SYNECDOCHE, and perhaps several others. By the natural progress of language, words or phrases at first employed as tropes become impressed so strongly with their new or derivative signification, that they finally lose the original.

Trophi (Gr. τροφός, from τρέφω, *I nourish*). A name given by Kirby to the different instruments of, or organs contained in the mouth of insects, or closing it, and employed in manducation or deglutition. They include the *labrum*, *labium*, *mandibulæ*, *maxillæ*, *lingua*, and *pharynx*.

Trophonius (Gr. Τροφώνιος). In Greek Mythology, a son of Erginus, king of Orchomenos, who, together with his brother Agamedes, built the temple of Apollo at Delphi. He prayed for a reward from the god, which was promised him on the seventh day, on which he and his brother were both found dead. The story is also told in other ways. He had a temple at Lebadea, in which was the celebrated cave into which persons descended to consult the god. But the impressions produced by the descent were thought so to work upon the spirit of a visitor, that he remained a victim to melancholy the remainder of his life. Hence arose the proverb applied to a serious man—that he looked as if he came out of the cave of Trophonius.

Trophsperm (Gr. τρέφω, *I nourish*, and σπέρμα, *a seed*). A name given by some French botanists to the placenta of a plant.

Trophy (Gr. τρόπαιον, from τρέπω, *I turn*). A monument consisting of some of the arms of slain enemies, hung upon the trunk of a tree, or a stone pillar, by a victorious army, in token of its victory and the flight of the enemy; whence its name. Trophies were always dedicated to some deity, whence it was deemed sacrilegious for any one to injure or demolish them; while at the same time it was forbidden to repair them when decayed. (Paris ix. 40; see, as to Roman trophies, *Mém. de l'Acad. des Inscr.* xxiv. 32.)

Tropical Year (Gr. τροπικός, *belonging to a turn*). The time between the sun's leaving a tropic and returning to it. Popularly it means the time from the longest day in one year till the longest in the next. [YEAR.]

Tropics. In Astronomy, the parallels of declination between which the sun's annual path in the heavens is contained, the distance of each from the equator being equal to the sun's greatest declination. The northern tropic is called the tropic of Cancer, and the southern one that of Capricorn, from their touching the ecliptic in the first points of those signs.

The distance of the tropics from each other is equal to the difference between the greatest and least meridian altitudes of the sun, observed at any place whose latitude is greater than the obliquity of the ecliptic. [ECLIPTIC.]

Tropidonotus (Gr. τρόπις, *a keel*, and νῶτος, *the back*). A genus of non-venomous serpents, nearly allied to the true Colubers, but with bodies thicker in proportion to their length; the back more keel-shaped, and the abdomen more expanded and convex; the head is large and conical, with a slender and short muzzle. The species seldom exceed three or four feet in length; they live near fresh-water streams, and are good swimmers: they are confined to the Old-World continents, and are replaced in South America by the genus *Homalopsis*. The *Coluber scaber*, Linn., a serpent of the Cape of Good Hope, remarkable for the presence of teeth in the œsophagus, and their absence from the mouth, is referred to the genus *Tropidonotus* by Schlegel.

Troubadours (Ital. trovar, Fr. trouver, *to find*). A school of poets who flourished from the eleventh to the latter end of the thirteenth century, principally in the South of France, but also in Catalonia, Arragon, and the north of Italy. They wrote in varieties of the Provençal or Romance language, also called in the middle ages *Langue d'oc*. They flourished under the counts of Toulouse, Barcelona, and Provence; and their minstrelsy and peculiar spirit declined from the time of the crusade against the Albigenses, when the former of these noble houses was vanquished and humiliated, and their land overrun by the sterner adventurers of the north. The most renowned among the Troubadours were knights, who cultivated poetry as an honourable accomplishment; but their art declined in its later days, when it was chiefly cultivated by minstrels of a lower class. The names and some of the productions of more than 200 Troubadours have been preserved, and among their numbers are to be found kings, dukes, counts, and warriors of historical celebrity. The most remarkable characteristics of the Provençal poetry were its almost entire devotion to the subject of romantic gallantry, and the very complicated character, in general, of its metre and rhymes. The principal species of composition cultivated by the Troubadours were *tenzones*, or poetical contests between two minstrels; sometimes breathing satire or defiance, sometimes rivalling each other in the praise of their ladies, sometimes aiming at mere exertions of verbal ingenuity; *sirventes*, pieces devoted to martial and other serious subjects; short songs, or *chansons*; and a variety of other lyrical strains, *soulas*, *lais*, *pastourelles*, *arbades*, *serenades*, *retronage*, and *redondes*. The earliest Italian poets framed their style of thought and versification closely after the model afforded them by the Troubadours. (Sismondi, *Literature du Midi de l'Europe*, vol. i.; the works of M. Raynouard; Lewis's *Researches into the Romance Language*; Schlegel, *Obs. sur la Langue et Lit. Provençale*; Milman, *Latin Christianity*, book xiv.; Hallam, *Literary History of the Middle Ages*, ch. ix. part i.; *National Review*, July 1858, p. 74; Thierry, *Conquête de l'Angleterre par les Normands*, iii. 221.)

Trough of the Sea. The low portion between the lines of crests of two waves. Waves being raised by the wind, the trough must be at right angles to its direction. Hence to be lengthways in the trough is the worst position for a ship in regard to rolling.

Trous de Loup (Fr.). In Military operations, rows of pits in the form of inverted cones, and with a pointed stake in each. They form an obstacle to the advance of cavalry. They should not be more than two and a half feet deep, lest the enemy's riflemen should make use of them.

Trout (A.-Sax. truht). This name is restricted properly and specifically to the *Salmo fario* of Linnæus; but is applied in a generic sense to other native species of *Salmo*, the *S. eriox* of Linnæus, which is the *S. salar* of Rondeletius, being called the bull-trout and grey trout; the *Salmo ferox*, the great grey trout, or lake-trout; the *S. trutta*, the salmon-trout, &c. The common trout inhabits most of our lakes and rivers, and is subject to many varieties of colour, proportions, and even of internal structure, as in the stomach of the gillaroo-trout, according to the variations of soil and food. The season of spawning with the trout is generally in the month of October, at which period the gravid fish make their way up the stream to the shallows. Trout are in finest condition from the end of May to September.

Trouvères or **Trouveurs** (Fr. from trouver, *to find*). Another form of the word Troubadour, employed as a name to distinguish the vernacular poets of Northern France from the Provençal Troubadours. The flourishing period of these poets was the era of the Crusades, and to them belong the stories of the Carolingian cycle, of Charlemagne and his peers, of Arthur and his knights, of Roland and the sons of Aymon. The productions of the trouvères were closely imitated by the monkish poets who wrote in Latin, but who seem to have been unaware of the fact that 'no great poet is inspired but in his native language.' (Milman, *Latin Christianity*, book xiv. ch. iv.)

Trover (Fr. trouver, Ital. trovare, *to find*). In Law, an action of tort. It is a species of action on the case [Action], which is employed to try a disputed question of property in goods and chattels. The declaration in trover contained, previously to 1852, a formal allegation that the plaintiff lost, and the defendant found, the goods in question; but this legal fiction is now abolished, and the action is brought on a simple allegation that the defendant converted to his own use, or wrongfully deprived the plaintiff of the use and possession of, the plaintiff's goods.

Troy, War of. Attempts have been made by chronologers to assign a date to the war of Troy, on a retrospective calculation from the opinion of Herodotus that Homer lived some four centuries before his own time, and that the Trojan war was, in the supposed age of Homer, a comparatively recent event. It must, however, be first proved that there was a single author named Homer, for the *Iliad*, or *Odyssey*, or for both [Epic; Homeric Poems], and that there really was an historical Trojan war. On both of these points no evidence, apparently, is forthcoming. Of the author or authors of the *Iliad* we know nothing: and the tale which the Homeric poets have left to us of the struggle to avenge the wrongs and woes of Helen is essentially a story in which the main chain of causation is superhuman, in which the gods mingle visibly with men, and the heroes themselves are the sons or husbands of immortal beings. From this narrative, full of an astounding thaumaturgy, Thucydides, by rejecting all the incidents as utterly improbable, and substituting political motives adequate to explain the movements of the contending forces, has extracted or rather fabricated a story thoroughly probable in itself, but for which we have less historical evidence than for the story of Robinson Crusoe. In short, his thoroughly prosaic and possible narrative is a piece of plausible fiction of no greater value than the version of Dio Chrysostom, which gives an account of the war diametrically opposed to that of the *Iliad*, which represents Paris as the lawful husband of Helen, and Achilleus as slain by Hector, while the Greeks retire, disgraced and baffled, without taking Troy. We are not, perhaps, justified in maintaining the negative position, that no war actually took place in the Troad; but we have as little warrant for asserting that there was. The burden of proof lies on those who assert that the Trojan war is historical, as for those who maintain the existence of gorgons, griffins, and basilisks. 'If,' says Mr. Grote, 'we are asked whether it be not a legend embodying portions of historical matter, and raised upon a basis of truth—whether there may not really have occurred at the foot of the hill of Ilion a war purely human and political, without gods, without heroes, without Helen, without Amazons, without Ethiopians under the beautiful son of Eos, without the wooden horse, without the characteristic and expressive features of the old epical war—like the mutilated trunk of Deiphobus in the under world; if we are asked whether there was not really some such historical Trojan war as this, our answer must be that, as the possibility of it cannot be denied, so neither can the reality of it be affirmed.'. (*History of Greece*, part i. ch. xv.)

But whatever may have been the source of the legend, or its original meaning, it is certain that it became localised in the north-western corner of Asia Minor, just as other myths become localised at Delos, Ortygia, Crete, Athens, and Eleusis. The historical Ilion had its acropolis called Pergamos, in which was shown the house of Priam, and the altar at which he had been slain, and where the panoplies worn by Homeric heroes were exhibited to admiring crowds, who believed

in their genuineness as firmly as the pilgrims to Trèves still believe in the genuineness of the Holy Coat. On the altar where Priam fell, Alexander the Great offered a solemn sacrifice, from the wish to appease the anger of the old Trojan king against the Macedonian stranger who belonged to the race of the Achilleids. The reputation of this historical Ilion was eclipsed for a time by the foundation of Alexandreia Troas, until the Romans granted to it immunity from tribute, with other honours, as being the spot whence their progenitor Æneas had started on his westward wanderings. Hence arose a jealousy between the Ilians and the inhabitants of Alexandreia Troas and other cities, who made an attack on the genuineness of the Trojan sites and ventured to assert that the Homeric Ilion had not occupied the site of the city so called. Whatever may have been the value of these doubts, the legendary faith continued unshaken, and its upholders vindicated for it the weight of authority even against historical impossibilities. 'Hellanikus, Herodotus, Mindarus, the guides of Xerxes, and Alexander had not been shocked by them: the case of the latter is the strongest of all, because he had received the best education of his time under Aristotle; he was a passionate admirer and constant reader of the *Iliad*; he was moreover personally familiar with the movements of armies, and lived at a time when maps, which began with Anaximander, were at least known to all who sought instruction.' To resist such a weight of authority as this, would argue an extreme hardihood of scepticism.

But although it is no part of the historian's office to write the history of a period for which he has no materials coming to him as the known evidence of trustworthy contemporary witnesses, the mythologist may analyse the legendary narrative, and ascertain its points of resemblance or difference, as compared with the epic poems or the traditions of other ages and countries; and something at least is done when the names of many among the chief actors in the struggle are found in the earlier literature of the Hindus. Some steps are gained towards a settlement of the question when we learn that PARIS represents the Pânis who seek to seduce Saramâ (Helen) from her allegiance to Indra, that Briseis recurs in the name Brisaya, that Athênê is Ahanâ, that Achilleus is the solar hero Aharyu. With this must be taken the large number of names which explain themselves [TELEPHASSA], and the analogies in the lives and character of Homeric heroes, and those of other mythical personages, as in the part played by Patroclos, PHAETHON, and TELEMACHOS, by Achilleus, MELEAGROS, and Paris, by Leto [APOLLO] and Hekabe [PARIS], by the agreement in the attributes of Zeus and Dyaus, of Phœbus and Indra, of Erinys and Saranyu, and in the identity of the ideas which underlie and pervade the conceptions of HERACLES, BELLEROPHON, ODYSSEUS, ACHILLEUS, SIGURDR, RUSTEM, THRAÊTANA, Baldr, THESEUS, PERSEUS, ŒDIPUS, and many more.

When the names of the chief actors, and the main incidents, as well as the general thread of the story, are thus found to be common elements in the Teutonic, Vedic, and Iranian mythologies, a presumption is at least raised that the whole epic is entirely mythical, and that it existed independently of any earthly locality, and the political movements of any tribes. In short, the fortunes of a geographical Ilion seem to fade away into the cloudland where the mythical 'Ilion like a mist rose into towers,' and no room is left for controversies whether such epithets as ἠνεμόεσσα, *windy*, or εὐρώδης (*broad*, or, as some would have it, *dark* or mouldy), apply especially to the site of the historical Ilion. If the evidence of comparative mythology be taken, Ilion was as open to the wind as the land of the PHÆACIANS, while εὐρώδης becomes a name quite as applicable to it as to Europa, Euryganeia, Eurymedusa, and other wives or daughters of solar beings.

Thus, then, the ordinary tests of HISTORICAL CREDIBILITY show that the events of the Trojan war could not have taken place in the way related, while comparative mythology has traced the materials of the tale into other ages and countries, between which and the Greeks intercommunication was impossible; and whatever be the opinion entertained as to the character of PARIS as representing the powers of light or darkness, it seems not easy to resist Professor Max Müller's conclusion that, 'apart from all mythological considerations, Saramâ in Sanskrit is the same word as Helene in Greek, and unless we are prepared to ascribe such coincidences as *Dyaus* and *Zeus*, *Varuna* and *Uranos*, *Sarvara* and *Cerberus*, to mere accident, we are bound to trace Saramâ and Helene back to the same point from which both could have started in common. The siege of Troy is but a repetition of the daily siege of the East by the solar powers, that every evening are robbed of their brightest treasures in the West. That siege, in its original form, is the constant theme of the hymns of the Veda. Saramâ, it is true, does not yield in the Veda to the temptation of Pani; yet the first indications of her faithlessness are there, and the equivocal character of the twilight which she represents would fully account for the further developement of the Greek myth. In the *Iliad*, Brisêis, the daughter of Brises, is one of the first captives taken by the advancing army of the West. In the Veda, before the bright powers reconquer the light that had been stolen by Pani, they are said to have conquered the offspring of Brisaya. The daughter of Brises is restored to Achilles when his glory begins to act, just as all the first loves of solar heroes return to them in the last moments of their earthly career.' (Max Müller, *Lectures on Language*, second series, xi.) For the singular parallelism which, even to minute details, runs through

the tales of the final conflict of Achilles and Hector, in the *Iliad*, and that of Odysseus and the suitors in the *Odyssey*, see Cox, *Tales of Thebes and Argos*, Introduction 63–110.

Troy Weight. An English weight chiefly used in weighing gold, silver, diamonds, and other articles of jewellery. The pound troy contains 12 ounces or 5,760 grains, the pound avoirdupois containing 7,000 of such grains. The name is supposed to have reference to the monkish name, given to London, of Troy Novant. [Weights.]

Truce (Mod. Lat. treuga, from the Teutonic treue, *truth*). An agreement between states, or those representing them, for the suspension of hostilities. Such an agreement, when made by officers of the state in the general exercise of their duty, and not authorised for the purpose expressly, or by necessary implification, ranks among that class of conventions which jurists term *sponsions*, and which are binding only if ratified. [Sponsion.] A general armistice or truce differs from a partial truce, which is limited to particular places; as between two armies, or between a besieged fortress and the besieging army. The former, in general, requires ratification: power to include the latter is held to be implied in the general authority of military and naval officers. (Vattel, book iii. ch. xvi.; Wheaton *On International Law*, vol. ii.)

Truce of God (Lat. *Treuga Dei*). A suspension of arms, which occasionally took place in the middle ages, putting a stop to private hostilities. The right to engage in these hostilities was jealously maintained by the inferior feudatories of the several monarchies of Europe. But it was restrained by the repeated promulgation of these truces, under the authority of the church. Thus, in the county of Roussillon, A.D. 1027, it was determined in a synod of the clergy, that no man should attack his enemy from the hour of nones on Saturday to the hour of prime on Monday. In 1041, a general 'truce of God' was accepted by the barons, first of Aquitaine, and then of all France, to last from the Wednesday evening of every week to the Monday morning following. This regulation was admitted by Edward the Confessor in England, in 1042, with some additions of great festivals and other days. It was confirmed by many councils, especially the Lateran Council of 1179. Philip Augustus of France introduced a new species of truce, termed the *quarantine*, by one of his ordinances. Under penalty of high treason, it restrained the family of an injured or murdered person from the commencement of hostilities until forty days after the commission of the act complained of. (For the general working of the system, see Milman, *Latin Christianity*, book viii. ch. vi.)

Truck. The small wooden cap at the extremity of a flag-staff, or at the mast-head. It is a small circular piece of wood with one or more pulleys for halyards to pass over.

Truck System. An arrangement by which an employer pays in kind or in goods, instead of in money. Such a method of paying wages is very early. Money was scarce in bygone times, and except for purchases from a distance was not needed. Even when a change took place in the value of money, and it became therefore accessible, it circulated but slowly, and tokens were freely stamped and issued by traders. This deficiency in money was long felt in the north of England, in which region the truck system naturally flourished.

If the employer were a benevolent and honest man, the supply of genuine commodities to his workmen in exchange for their labour, would be, as opposed to the high charges and frequent adulterations of small retail shops, a great boon. Clothing clubs, which take the money of labourers and expend it in large purchases at wholesale rates, are by no means an evil, but a great good, especially when the people are not pauperised by large grants under the name of interest. But the commercial relations of capitalist and factory operatives are not favourable to benevolence, and experience has unfortunately shown that the practice of the former was not even honest. The truck shops sold bad goods at exorbitant prices. In order to tie the factory hands to the masters, they encouraged a system of credit, and became as scandalous a public nuisance as roguery and helplessness could produce. The vile profits of the truck shop became a source of considerable and admitted revenue to the employers, and the workmen were paid at rates which, when compared with the real value of their earnings, were almost nominal.

The truck system was abolished by 1 & 2 Wm. IV. c. 37, not without opposition. It was urged against the action of parliament that it was undesirable to interfere with the freedom of trade; but those who use this righteous argument should take care that they are not striving to cover oppression and fraud under so sacred a term. Freedom does not mean the right of the strongest to oppress the helpless. The blemish of the Act was, that it was only made to extend to towns, and, like the Factory Children's Act, did not embrace within the provisions of its police the agricultural districts.

The Act of 1831 was preventive. But the most important means by which the workman can be supplied with goods of a trustworthy character, is by the establishment of co-operative stores of supply. The experiment has been tried successfully, and will have permanent effects. The system has several advantages. It secures the consumer from adulteration, for the consumers are the proprietors. It prevents the habit of credit in general articles of consumption, for no co-operative association can succeed which allows itself the risk of bad debts. [Co-operation.]

Trucks (akin to Gr. τροχός, *a wheel*). In Artillery, small thick round wheels of wood or iron. Also round blocks of wood, hollowed out at the centre, in which the feet of a gyn are placed, when the ground is bad.

True Bill. The formula by which the grand jury finds or approves a bill of indictment.

Truffle (Fr. truffe, Ital. trufa). Applied generally, the name Truffle (or Trubs) comprises all the *Fungi* which belong to the natural orders *Hypogæi* and *Tuberacei*. The Truffles, properly so called, belong, however, to the typical genera *Tuber*, and the closely allied genera *Chæromyces* and *Terfezia*.

The truffles of commerce all belong to the genus *Tuber*, of which several species are edible; the English Truffles belonging principally to *T. æstivum*, and the best French Truffles to *T. melanosporum*. These are black and warty externally, with the flesh variously marbled. The Piedmontese Truffles, on the contrary (which bear a high price, and are highly esteemed), are smooth, and within white more or less tinged with pink. Truffles are in this country sought for almost exclusively by dogs of a particular breed, but on the Continent sows are used for the same purpose, and they are raked up by persons who have a peculiar knack in recognising the spots where they are likely to grow.

All attempts have failed at cultivating them in the same way as mushrooms. In the South of France, indeed, truffles have been procured in woods by watering the ground, previously prepared, with water in which the parings had been steeped; but no one has yet been able to prepare spawn for sale in a form similar to that of mushroom-spawn. It is probable, however, that this will sooner or latter be accomplished.

Truffles require a calcareous soil, and in such soils they are, we believe, much more common than is usually supposed. They are by no means confined to beech-woods, but are found in England sometimes amongst oaks without any admixture of beech, and they do not dislike the neighbourhood of a few conifers. They have been seen sometimes so near the surface as to be cut off by the scythe when the grass is mown. Besides the edible truffles, which receive different names from collectors according to their degree of ripeness, there are several strongly scented or minute species, mostly with an even bark, which are either not esculent or too small to attract general notice.

The large white truffle belonging to the genus *Chæromyces* is too rare in England to be of much consequence, but it is a poor article of food. The African Truffle, belonging to the genus *Terfezia*, is a better esculent than the last, but not equal to the *Tuber æstivum*, though it appears of late to have attracted much notice in Algiers from its abundance; and numerous specimens have been also received from Mogadore. A species of *Hydnotrya* is sold abundantly in the market of Prague. The Red Truffle of the Bath market is a *Melanogaster*, and therefore belongs to *Hypogæi*, not *Tuberacei*. (Berkeley, *Treasury of Botany*.)

Trumpet (Ger. trompete, Ital. trumba, Swed. trumma, and thus akin to *drum*). In Acoustics, an instrument used for the purpose either of conveying articulate sounds to a great distance, or for applying to the ear, in order to collect the sonorous waves, and render sounds more distinct. In the former case the instrument is a *speaking-trumpet*; in the latter, a *hearing-trumpet*.

Speaking-trumpet.—The object of the speaking trumpet is to increase the intensity of speech, and transmit it to considerable distances in a particular direction. In order to obtain this effect, it is necessary that the aërial undulations which would disperse themselves in all directions be confined by the sides of the trumpet, and reflected so as to take, as nearly as possible, a direction parallel to the axis. This is accomplished by giving the trumpet such a form that its diameter becomes greater towards the extremity farthest from the mouth. A cylindrical or prismatic tube, of equal diameter throughout, assists powerfully in conveying sound from one extremity to the other, but contributes in no degree to give a direction to sound, or transmit it through free air.

The theoretical explanation of the effects of the speaking-trumpet is attended with considerable difficulty. Assuming that the reflection of sound takes place according to the laws of catoptrics, Lambert (*Berlin Memoirs for* 1763) shows that the best form of the instrument is a truncated cone, for the rays successively reflected from the interior surface of this figure make smaller angles with the axis after each successive reflexion. Cassegrain (*Journal des Savans*, tom. iii.) recommends the surface formed by the revolution of a hyperbola about its asymptote; and Kircher had previously proposed a truncated parabolic conoid, the mouth-piece occupying the focus. Some authors suppose that the trumpet should be formed of a very elastic material, in order to strengthen the sound by its vibrations. Others are of opinion that it should be without elasticity, to avoid the confusion that might be caused by the vibrations of the tube. Hassenfratz (*Journal de Physique*, tom. lvi.), who made a number of experiments on the power of the trumpet, by fixing a small watch in the mouth-piece, and observing the distance at which the beats ceased to be audible, found that the effects were precisely the same with a trumpet of tinned iron, whether used in its naked form, or tightly bound round with linen to prevent vibration, or when lined with woollen cloth, by which means reflexion was entirely prevented. It would appear, therefore, that neither the shape of the instrument, nor the material of which it is formed, is of much consequence. Leslie (*Experimental Inquiry into the Nature and Propagation of Heat*) supposes the effect of the trumpet to be owing to the more condensed and vigorous impulsion given to the air from its lateral flow being checked. 'The tube,' he observes, 'by its length and narrowness, detains the efflux of air, and has the same effect as if it diminished the volubility of that fluid,

or increased its density. The organs of articulation strike with concentrated force; and the pulses, so vigorously thus excited, are, from the reflected form of the aperture, finally enabled to escape, and to spread themselves along the atmosphere.' (P. 225.)

The invention of the speaking-trumpet is commonly ascribed to Sir Samuel Moreland, who, about the year 1670, proposed the best form of the speaking-trumpet as a question to the Royal Society.

Hearing-trumpet.—The hearing-trumpet, or ear-trumpet, may be considered as a reversed speaking-trumpet, with which it generally corresponds in form, though, for the sake of portability, it is often made curved or spiral. Lambert recommends the parabolic figure as the most advantageous; but, in order to give the greatest effect, the apex of the paraboloid must be cut off, and the mouth of a small tube inserted in the focus, to convey the sound concentrated at that point to the auditory organ. Various other forms are adopted in practice; and of late years, flexible Indian-rubber tubes have been brought into use, having a conical mouth-piece of ivory or silver at one extremity, and a small tube of like material to be applied to the ear. A trumpet of this kind may be used advantageously, not only for remedying the defects of the organ of hearing, but for assisting the observer to collect feeble and distant sounds. (Moreland *On the Speaking-Trumpet*, 1671; Chladni, *Traité des Sons*; Gehler, *Physikalisches Wörterbuch*, art. 'Hörrohr.')

TRUMPET. A musical wind instrument, usually made of brass, but sometimes of silver. This instrument formerly possessed but few notes; but in later times it has, by means of slides and keys, been vastly extended in its inflexions.

Trumpet Flower. A name applied to various large tubular flowers, as those of *Bignonia, Tecoma, Catalpa, Brunsfelsia, Solandra,* &c.

Trumpet Weed. The name of a sea-weed, *Ecklonia buccinalis,* belonging to the natural order *Laminariaceæ,* and very common and well known at the Cape of Good Hope. The stem is often twenty feet long, and is crowned at the top by a fan-shaped cluster of fronds, ten feet or more in length. The stem of this sea-weed, says Dr. Harvey, which is hollow in the upper portion, is when dried often used in the colony as a siphon, and by the native herdsmen is formed into a trumpet for collecting the cattle in the evening.

Truncate (Lat. truncatus, *maimed*). In Botany, this term is applied to bodies which terminate very abruptly, as if a piece had been cut off; as the leaf of the tulip-tree.

Trundle. In Mechanics, a pinion having its teeth formed of thick pins set in discs, otherwise called a *lantern wheel,* or *wallower.*

Trundle-head of a Capstan. The circular part at the top, with holes for the reception of the levers by which the apparatus is worked.

Trunk (Lat. truncus). In Architecture, the same as *shaft.* In the application of this word to a pedestal, it signifies the die, dado, or body of the pedestal.

TRUNK. In Entomology, this term signifies the intermediate section of the body which lies between the head and the abdomen.

Trunnions (Fr. trognon, *a core*). Short cylinders projecting from the sides of a piece of ordnance, by which it rests on its carriage or bed. They are generally about one calibre in diameter and length.

Truss (Fr. trousse, Dan. trosse). In Architecture, a framed assemblage of pieces of timber for the support of a principal beam or piece. [ROOF.]

TRUSS. On Shipboard, a rope confining the middle of a lower yard to the mast.

TRUSS. In Shipbuilding, timbers, or preferably iron plates, for giving a diagonal internal support to the side timbers or ribs.

TRUSS. In Surgery, an apparatus by which, in cases of rupture, the intestine is retained in the abdominal cavity. This is usually effected by the aid of a steel spring resting upon a small pad or cushion, which is kept in its place by a proper bandage.

Trussed Roof. In Architecture, one so constructed as to support the principal rafters and the beam at certain points where bending of the timber is likely to occur. [ROOF.]

Trust (Swed. trost, akin to troth, true, truce; Ger. treue, &c.). In Law, a term commonly used to designate any equitable right or interest as distinguished from a legal one: properly, that class of equitable rights supposed to be founded in the confidence placed by one party in another; the name *trustee* denoting the person in whom confidence is placed, and the term *cestui que trust,* signifying the person who trusts—in other words, the party who enjoys a beneficial interest in the objects of which the trustee has the legal property.

The origin of conveyances in trust may be traced to the fidei commissum of the Romans, which was a gift by will to a person capable of taking in trust for another who was incapable by the Roman law of taking such benefit, and whose claim under such gifts was for a long time precarious and merely fiduciary, but came at length to be recognised and enforced by law. With us, in the same manner, the original motive for the introduction of the fiduciary right, which was certainly borrowed from the Romans, was the wish to escape from the disabilities affecting certain persons, or bodies, or the liabilities attached to property in its direct and simple shape. Such was, in particular, the disability of corporations to purchase land; and on this account, as it is commonly said, the ecclesiastics, who were chiefly interested in this matter, introduced this new species of property, which was willingly recognised by the chancellors, who were usually ecclesiastics, and in other respects inclined to adopt the principles of the civil law. The clergy were, however, soon themselves deprived of the benefit of the invention, the

disability of corporations to take land being extended by statute to the new right so created. But there still remained many liabilities, arising from feudal tenure, incident to property at common law; such as, for instance, dower, escheat, wardship, restraint upon alienation by will, which it was desirable and possible either to evade by this mode of conveyance in trust, or to transfer to a quarter less likely to be affected by them: and there were also many modifications of property for the benefit of families, which could only be given in this manner. It is said, further, that there were less honest purposes, such as the defrauding bonâ fide purchasers by secret alienation, sought to be attained by the same means. For these, among other reasons, conveyances in trust were still resorted to; and the Court of Chancery, which had once, for whatever reason, originally recognised, continued to enforce them.

There were also two methods of creating a trust, or rather raising a use, without an actual conveyance: the one by agreement for money; the other by covenant under seal in consideration of near *relationship*.

The right so created was called indifferently a *trust* or *a use*; more commonly the latter, from the actual enjoyment of the rents and profits annexed to it in equity. Indeed, the benefit of the use or trust was, in the first instance, confined to this; but the cestuis que use, or parties beneficially interested, soon acquired the right of directing a conveyance by the holders of the legal estate, technically termed the *feoffees to uses*, and also of calling upon them to use the legal title in their defence in a court of common law. [USE.]

Several statutes were passed at different times, giving to the owner of the use or trust partial legal rights, and partially also subjecting interests of that sort to legal liabilities, before the celebrated statute, commonly called the Statute of Uses, which was passed in the twenty-seventh year of Henry VIII. The general object of this statute, as stated in the preamble, was to prevent those secret and fraudulent transfers occasioned by the separation of the real from the apparent ownership, and to restore those rights of the feudal lord, and of the crown, which had been in a great measure evaded by keeping the legal title (to which alone they attached) in a course of succession where it was unlikely to be forfeited by treason, and where it was less frequently subject, by descent to an infant heir, to the burden of wardship and relief. The general effect of the statute, as stated in the title, was the transferring or changing the use into possession, i. e. annexing to the use the legal right of possession, whereby the real owner would be made manifest to all, and the real ownership would become subject to all the liabilities incident to the legal title: in short, the distinction between equitable and legal rights would be abolished, and the adjudication on all questions of property, except in particular cases of fraud or accident, would be restored to the courts of common law.

The statute, however, was so worded as not to apply either to copyholds or leaseholds, nor indeed to personal property of any description, which at that time was little thought of; so that equitable rights in copyholds and personalty remained as before, merely equitable; and they arose again, very shortly afterwards, in every species of real property, it being held by the courts of common law that only such uses or trusts were executed and transferred into possession by the statute, as were raised or declared upon what was *before* the statute the legal seisin or estate; so that where a new legal estate taking effect as such by virtue of the statute was created or conveyed in trust, such trust-right, not being within the purview of the statute, and not being recognised by the courts of common law, was adopted and enforced in equity, for reasons altogether similar in kind to those which originally led to the introduction of uses.

Hence a new system of equitable rights grew up under the name of *trusts*, commensurate with the new system of legal rights or uses (for the use henceforth denoted the legal estate), created by the statute; and though some of the peculiar advantages of the old trust were, by the effect of the statute, transferred to the new legal ownership (such as the capability of modification for the benefit of different parties upon different events), and though the right of disposition by will was shortly afterwards extended to it by special statute, and though whatever advantages were still possessed by the *trust*, as a means of evading the burdens of tenure or the other liabilities now annexed to the *use*, were gradually removed either by the abolition of those burdens or the extension of those liabilities, trusts still continued and continue to be habitually resorted to for various purposes. These are, generally, either to protect the interests of married women and children, by placing in the hands of trustees for them the legal rights which they would be incapable of exercising; or to secure the rights of those in remainder, by severing from the usufruct of property for a life the power of disposing of the whole; or, lastly, the convenience of management, where many parties are interested in the same subject.

These observations can apply, at least with one or two exceptions, only to *express trusts*. An express trust supposes a legal transfer of the property actually completed, and a declaration in the same instrument, or having reference to the same instrument, of the trust upon which the property so transferred is to be held; and the ground upon which such trust rests is the express confidence that is placed in the trustee by the person who transfers the property to him, no consideration of money or blood between the trustee and those for whom he holds being required as an inducement for the interference of equity.

Trusts are most commonly raised by marriage settlements, or by will. [SETTLEMENT.] The usual trusts in the former case, as to real estate, are, in the first place, for securing to the wife payment of her pin money during marriage, and of her jointure after the husband's death; then for the raising the stipulated provisions for younger children, and also for providing for their maintenance during minority. Similar trusts, also, are commonly raised in wills, for the maintenance or advancement and portioning of children. In all such cases, the legal rights vested in the trustees most commonly remain in their hands, as a means only of compelling the person actually in possession to discharge those claims subject to which he holds his estate. But it is in regard to that sort of personal property, the title to which, or rather the power of conferring a title to which, is annexed to the possession, either from the nature of the thing itself, as in the case of money, or for reasons of public convenience, as in the case of stock in the funds (a class of property over which the holder, whether it be in trust or not, has by the regulations of the Bank absolute power of alienation) and other similar investments, such as shares in public companies, &c., that the utility of trusts is more particularly conspicuous. Whenever it is sought to create in any such property shifting or partial interests, nothing in such cases can secure future or contingent rights from the dishonesty of the tenant for life or partial owner but the intervention of trustees, in whose hands the whole legal interest, i.e. the whole power of alienation, resides; and though a similar danger is sometimes to be apprehended even at their hands, yet their number itself, and the discretion that may be exercised in their appointment, afford a greater security than is to be found in the integrity of a single individual.

Trustees are bound to act in strict accordance with the terms of their trust and the rules of the Court of Chancery, and will be made answerable for the consequences of any breach of trust, however innocent. They are liable not only for such sums as they actually have received, but for such also as they might, but for their wilful neglect or default, have received. Where there are several trustees, each is generally liable for his own acts and receipts only; but where all concur in empowering either one of themselves, or a third party, to do or receive that which he could not do or receive but by virtue of such authorisation, all are responsible for his acts and receipts under such joint authority. It is the duty of trustees, besides being faithful accountants, to apply and distribute rightly the property with which they are intrusted according to the various rights of the parties entitled to it; and they are liable for any misapplication, arising either from ignorance of facts which they ought to have known (i.e. might by common diligence have known), or from ignorance of the law in any case, and this although they may have acted in perfect good faith, and in reliance on the opinion of eminent legal advisers. The rights of trustees are confined to the reimbursement of their proper expenses out of the trust property. An express trust will not fail for the want of trustees; where none are nominated, the Court of Chancery will take upon itself the appointment.

In the case of *implied* or *resulting* trusts, the confidence is not expressed, but implied by courts of equity from the want of consideration or motive apparent in such cases, to give away the whole, or, as it may be, any part of the beneficial interest. Such trusts arise, for instance, upon the conveyance or transfer, by deed or will, of property, real or personal, upon some trust expressly declared, which does not exhaust the whole beneficial interest, or expressly upon trust, though no trust be declared: in the first of which cases, the surplus of the beneficial ownership, after satisfaction of the express purpose or trust, and in the second case, the whole of the ownership, results to the party making such conveyance or transfer.

Trysail. A small gaff sail of strong or storm canvas, set in bad weather.

Trythings. A division of counties into three parts, ascribed to Alfred. The word survives in the *Ridings* of Yorkshire.

Tsabaism. [SABAISM.]

Tscheffkinite. [TSCHEWKINITE.]

Tschermigite. A kind of ammonia-alum found in the Brown-coal formation of Tschermig in Bohemia.

Tschewkinite. An amorphous mineral of a velvet-black colour found near Miask in the Ilmen mountains and in the granite of the mountains of Siberia. It is composed chiefly of silica, titanic acid, protoxide of iron, lime, and the peroxides of cerium, lanthanium, and didymium. It is named after General Tschewkin.

Tschirnhausen's Transformation. Tschirnhausen's transformation of an algebraic equation has for its object to cause the disappearance of certain terms, and thus to facilitate its solution. This is accomplished by the introduction of a new unknown quantity y connected with the x of the given equation, say of the n^{th} degree, by the relation—

$$y = a_0 + a_1 x + a_2 x^2 \ldots + a_{n-1} x^{n-1},$$

where a_0, a_1 &c. are disposable coefficients. The elimination of x between this and the original equation leads to another in y of the n^{th} degree. Tschirnhausen published this method in the *Acta Eruditorum* of Leipzig in 1683, and it has since been employed by numerous writers. Prof. Cayley, in *Crelle's Journal*, vol. lviii. 1861, and in the *Phil. Trans.* 1862, has given the transformed equations for cubic, quartic, and quintic equations.

Tschudic or Chudic Languages. By this name are known those dialects of the Finnic class, which are spoken by the Lapps, Finns, and Goths, the other three branches being the Ugric, Bulgaric, and Permic. [TURANIAN LANGUAGES.]

Tsebaoth. [SABAOTH.]

Tube (Lat. tubus). In Artillery, a barrel of quill, paper, or metal, driven with mealed powder damped with methylated spirit, and having at the top a cup or head, varying in form and nature. In the British service all barrels of tubes are $\frac{2}{10}$ inch in diameter, and the vents in which they are placed $\frac{2}{8}$ inch. A hollow is made down the middle of the composition, so that its whole length may be ignited at once, and the large amount of gas thus generated in a small channel acquires sufficient force to fire the charge of powder in the gun.

There are several kinds of tubes in the service. The *common quill*, *Dutch*, and *common metal*, require to be fired by a portfire. The *cross-headed* or *detonating quill* is fired by a lock, the hammer striking a *crosspiece* or *snipe* containing detonating composition. The *copper friction*, for land service, and *quill friction* for naval service, are fired by a lanyard, the hook of which is fixed into a ring in a roughened friction bar, which is then pulled through detonating composition at the head of the tube. The *galvanic* and *electric* tuoes are fired by a galvanic battery or a magnet respectively. The latter, which is now used for the proof of guns, has an egg-shaped head, containing two copper wires, to the lower poles of which an explosive composition is pressed. The tube is connected with the magnet in a splinter-proof, by copper wires, and when the current circulates from the magnet, the spark ignites the explosive composition, and fires the tube.

TUBE. In Botany, the part of a monosepalous calyx, or monopetalous corolla, formed by the union of the edges of the sepals or petals. The same term is also applied to adhesions of stamens.

TUBE. A pipe or long hollow body. A tube is generally understood to signify a hollow cylinder, but the cylindrical form is not essential.

Tuber (Lat. *an excrescence*). In Botany, any roundish underground succulent stem, covered with buds, from which new plants or tubers are produced; as the potato. [PROPAGATION OF PLANTS.]

Tubercle (Lat. tuberculum, *a small tuber*). A material which, deposited in various parts of the body, destroys the tissues infested. When the lung is attacked, tubercular pulmonary consumption is the consequence; while, if the brain or the abdomen be affected, we have to fear the occurrence of water on the brain (hydrocephalus) or of disease of the mesenteric glands. Tubercle must be regarded as the result of a constitutional morbid state, either hereditary or acquired. The deposit of tubercle appears to be determined by several causes, such as mal-assimulation, bad diet, deficient ventilation, &c. The latter cause is regarded by a recent writer, Dr. MacCormac (*On Consumption*), as the great source of the evil. He undertakes to prove, (1) that rebreathed air induces tubercle, and (2) that no other known cause induces it.

Tubercle of Lower. An eminence in the right auricle of the heart where the two venæ cavæ meet; it was first described by Richard Lower, in 1665.

Tubercula Quadrigemina (Lat.). Four white oval tubercles in the brain, two of which are situated on each side, over the orifice of the third ventricle and the aqueduct of Silvius. The old anatomists called them *nates* and *testes*.

Tubercule (Lat. tuberculum). In Botany, a term applied to simple roots which acquire a succulent condition, become reservoirs of vegetable food, and serve for propagation in consequence of being terminated by a bud. A little tuber.

Tuberose. The fragrant-blossomed Liliaceous plant, called by botanists *Polianthes tuberosa*.

Tubicoles (Lat. tubus, *a tube*, and colo, *I inhabit*). The name of an order of Anellidans, comprehending those which live in tubes, and which are Cephalobranchiate; also the name of a family of Lamellibranchiate Acephalous Molluscs, including those which have a tubular calcareous sheath in addition to the two shelly valves.

Tubicorns (Lat. tubus, and cornu, *a horn*). The name of a family of the order of Ruminants comprehending those in which the horns are composed of a horny axis covered with a horny sheath.

Tubifers (Lat. tubus, and fero, *I bear*). The name given by Lamarck to an order of the class *Polypi*, comprising those which are united upon a common substance fixed at the base, and the surface of which is wholly or partially covered with retractile hollow tubes.

Tübingen School. A name applied to the theological writers belonging to the university of Tübingen, whose chief characteristic is their opposition to all mystical or euêmeristic interpretations of the various books of the Old or New Testament. Among the most prominent writers of this school are Strauss, Baur, and Zeller. Of these, the first is the great antagonistic of the euêmerist or rationalistic method of Dr. Paulus, who professed to account for all miracles as exaggerated or distorted accounts of ordinary events. This method he displaced by the theory of the mythus, as furnishing the materials for narratives which have grown up round a nucleus which he allows to be historical; but although the writers of this school may on this theory of myths differ somewhat in opinion, they all agree in excluding sentiment and imagination from all attempts to determine the character of the early Christian church or the teaching of its Founder. (Mackay, *The Tübingen School and its Antecedents*.)

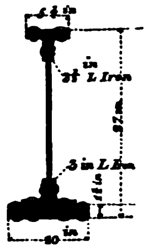
Tubipores (Lat. tubus, and porus, Gr. πόρος, *a passage* or *pore*). The name of a family of Zoophytes, comprehending those in which the animals are isolated and contained in elongated cylindrical calcareous cells, attached by their base, and strengthened by cross bars at definite distances.

Tubular Bridge. A bridge formed of a great tube or hollow beam, through the centre of which a roadway or railway passes. The most remarkable bridge of this kind was designed by Mr. Robert Stephenson for carrying the Chester and Holyhead Railway over the Menai Straits, for although the bridge since carried across the St. Lawrence is of much greater total length, the width of each of its constituent spans is less. The Menai bridge consists of two rectangular tubes of wrought-iron plates riveted together; one tube being for the accommodation of the up line of rails, and the other for the accommodation of the down line of rails. A pier erected upon a rock in the middle of the straits divides each tube into two spans of 462 feet each, and there is also at each end a smaller tube of 230 feet span to serve as approaches to the bridge. These several tubes are joined together so as to form one long tube for each line of rails of the total length of 1,524 feet.

The thickness of the central pier is 45 feet, of the side piers 32 feet each, and the tube projects 17 feet 6 inches over the masonry at each end. The bridge contains 9,480 tons of wrought iron, 1,988 tons of cast iron, and 1,500,000 cubic feet of masonry. The total expense of its construction was 601,860*l.*, of which the iron work cost 443,160*l.* and the masonry 158,700*l.* It was commenced on the 10th of August, 1847, was finished on the 5th of March, 1850, and was opened for traffic on the 18th of March, 1850. A similar bridge of one length of tube and of a somewhat smaller span had been previously erected, under Mr. Stephenson's direction, over the river Conway on the same line of railway. This bridge was opened for traffic in 1848.

History of Tubular Bridges.—On the occasion of an entertainment given at the opening of the Conway bridge in 1848, Mr. Stephenson gave an account of the circumstances which had led to the conception of the plan of carrying a railway over a river or chasm by employing as a bridge a hollow beam or tunnel constructed of iron plates. About six or seven years before he had been called upon to construct a bridge on the Northern and Eastern Railway at Ware under certain limitations imposed by Act of Parliament which rendered bridges of the ordinary forms inapplicable; and he thereupon resolved to employ malleable iron beams, by the aid of which a cellular platform was made which answered the exigencies of the occasion. In this cellular platform, however, there does not appear to have been much novelty of conception, for it was merely an arrangement of beams of the ordinary form of railway girders, and the only peculiarity of these beams was that they were made of wrought iron instead of cast iron as had been the previous practice. They were proportioned moreover in the same manner as cast-iron beams—as will be seen by fig. 1, which is a cross section of one of them—whereas it is now known that malleable iron beams should have the top and bottom flanges of about the same dimensions. However, from the suggestions of this structure, the idea of a tubular bridge first arose in Mr. Stephenson's mind, and in his original conception he appears to have contemplated the use of elliptical or cylindrical tubes supported by chains. Mr. Stephenson's engagements did not permit him to work out this idea, or to put it into such a practical form that he would have himself had confidence in carrying it into execution. He therefore delegated this task to his assistants, who, taking up the idea where Mr. Stephenson had left it, pursued the enquiry with great ardour and sagacity until they finally brought the idea into the form in which it was carried into practical effect.

Fig. 1.



Long before this time, however, a form of bridge much more nearly resembling that finally adopted for crossing the Menai Straits than Mr. Stephenson's cellular platform at Ware, or even than his subsequent conception of an oval or cylindrical tube supported by chains, had been successfully introduced in Switzerland; but the bridges which had been erected upon this plan, instead of being made of wrought iron, were constructed of timber. The first of these bridges appears to have been erected over the Rhine at Schaffhausen by Jean Ulrich Grubenmann in 1757. It consisted of two spans—the one of 170 feet, and the other of 193 feet. In 1778 another bridge of a similar construction was built by the same person over the Limmat at Wettingen. The span of this bridge was 390 feet. Fig. 2 is a section of this bridge at the ends, and fig. 3 is a section at the centre. It will be apparent from these figures that this bridge is composed of a platform for the roadway, two side frames of carpentry, and a roof, so that it in fact constitutes a great hollow timber beam of a nearly rectangular form. These bridges were both burnt by the French in 1799, after having remained in constant use, the one for forty-two years and the other for twenty-one years. Armies, artillery, and heavy weights, had passed over them in

Fig. 2.

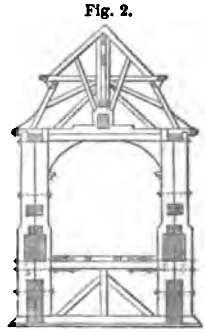


Fig. 3.

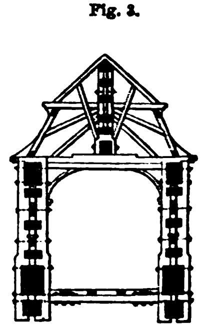

safety, and they appear to have perfectly fulfilled the purpose for which they were designed. Each of the side frames was raised into its place by means of powerful screw jacks resting on piles.

Subsequently to this time, lattice timber bridges came into considerable use in America. These bridges consist of two or more great frames of carpentry formed of planks or timbers crossing one another diagonally, and bolted at top and bottom to shelf pieces. The lower shelf piece carries a platform which forms the roadway, and in some cases the top is also covered with lattice work so as to convert the bridge into a hollow lattice beam. In a few cases these lattice bridges were formed of iron, and in Boston there is an elliptical tubular lattice bridge of iron of 120 feet span. This bridge had been in use a few years before the construction of that cellular platform at Ware which Mr. Stephenson says first suggested to his mind the idea of a tubular bridge. Lattice bridges formed of bars of iron have of late years come into use in this country, and have been very largely employed in India and other countries possessing large rivers, over which railways have to be carried. [VIADUCT.] An excellent example of a lattice bridge is the one carried across the Thames at Blackfriars for the London, Chatham, and Dover Railway, and such bridges are now generally preferred to tubular bridges formed of iron plates.

In entering upon the consideration of the best mode of carrying out Mr. Stephenson's idea, it occurred to Mr. Fairbairn, upon whom this responsibility now devolved, that the most judicious course would be to institute a series of experiments to determine the breaking weight of beams or tubes of different forms, with the view of ascertaining what form of tube would reconcile the greatest amount of strength with the least quantity of material, and also what load a tube of a given form and of given dimensions could with safety sustain: these experiments were accordingly instituted, and they speedily furnished information of great practical importance. It was very soon found that oval and cylindrical tubes were not of so eligible a form as rectangular ones; and it was further found that in rectangular tubes the strength should be chiefly concentrated at the top and bottom, and in nearly equal proportions. It also occurred to Mr. Fairbairn that it would be advisable to make the top and bottom of the tube of a cellular form, which would obviate the necessity of using plates of such a thickness as could not be so securely riveted. This construction, it was anticipated, would also impart greater stiffness to the structure, and render the top less liable to buckle up when a heavy strain was applied.

Experiments to determine the best Form of Tube.—The first experiments were made upon cylindrical tubes formed of iron plates, riveted together like the chimney of a steamboat. The tube experimented upon was laid horizontally between two supports, and a small hole was cut in the centre of its lower side to enable a rod of iron to pass through; from this rod of iron the weights employed to ascertain the strength were suspended; around the hole a collar was riveted so as to impart as much strength to that part of the tube as before the perforation had been made, and a cushion of hard wood 8 inches square was fitted to the interior of the tube above the perforation. Through this piece of wood the rod which carried the weights ascended, and a cutter passing through the end of the rod rested on a square plate of iron superimposed upon the wood, so that from the wooden cushion the whole weight depended. Many of the tubes gave way by tearing at the riveting of the plates; but some also broke from the compression at the top. The more important results of these experiments are exhibited in the following tables:—

Strength of Cylindrical Tubes used as Beams.

Number of Experiment	1	2	3	4	5	6	7	8	9
External diameter	12·18 in.	12 in.	12·4 in.	18·26 in.	17·68 in.	18·18 in.	24 in.	24·3 in.	24·2 in.
Length between supports	17 ft.	17 ft.	15 ft. 7½ in.	23 ft. 5 in.	23 ft. 5 in.	23 ft. 5 in.	31 ft. 3¾ in.	31 ft. 5¾ in.	31 ft. 3½ in.
Thickness of plates	0·0408 in.	0·037 in.	0·131 in.	0·0582 in.	0·0631 in.	0·1190 in.	0·954 in.	0·119 in.	0·98 in.
Weight of tube	102 lbs.	107 lbs.	392 lbs.	334 lbs.	346 lbs.	777 lbs.	1,007 lbs.	1,385 lbs.	1,085 lbs.
Greatest deflection	0·39 in.	0·65 in.	1·20 in.	0·56 in.	0·74 in.	1·19 in.	0·63 in.	0·93 in.	0·72 in.
Breaking weight	3,010 lbs.	2,704 lbs.	11,440 lbs.	6,400 lbs.	6,400 lbs.	14,240 lbs.	9,760 lbs.	14,240 lbs.	10,880 lbs.
Broke by compression or extension	Compression	Compression	Extension	Extension at rivets	Extension at rivets	Extension at rivets	Extension at rivets	Extension at rivets	Extension at rivets

The thickness of the plates in these experiments was ascertained by cutting a portion of the plate into small pieces and screwing these pieces together in a vice. The collective thickness was then accurately measured, which divided by the number of pieces gave the thickness of each. It appears probable that the whole of the tubes would have been broken by compression, but for the weakening of the bottom caused by the rivet holes, which generally produced fracture by extension in that part.

The ends of the tubes where they rested upon the supports had to be kept in shape by circular pieces of wood inserted into them. When these pieces of wood were withdrawn, the ends were flattened horizontally. At the same time the centre of the tube was flattened vertically by the action of the weight hanging at the under side, and in looking endways at the tube the two sections made a species of cross—the ends forming the horizontal part of the cross, and the centre the vertical part.

The following are the results of the experiments made with elliptical tubes:—

Strength of Elliptical Tubes used as Beams.

Number of Experiment	1	2	3	4	5	6
Major axis	14·625 in.	21·66 in.	21·25 in.	15 in.	12 in.	13 in.
Minor axis	9·25 in.	13·50 in.	14·123 in.	9·75 in.	7·5 in.	8 in.

Nos. 5 and 6 of the foregoing experiments were not made with simple elliptical tubes, but the tube employed in No. 5 was an elliptical tube with a fin at the top (fig. 4), and the tube employed in No. 6 was more of a rectangular form with a fin at the top (fig. 5).

Fig. 4. Fig. 5.

These top fins were not found to operate advantageously, as they were thrown into compression before the strain came on the top of the tube itself, and the strength was thus overcome in detail.

The most important of the experiments, however, are those upon rectangular tubes, the results of which are as follows:—

Strength of Rectangular Tubes used as Beams.

These experiments, with a few others of a similar character, which it would be needless to recapitulate, having been concluded, Mr. Fairbairn directed his attention to the determination of the proportions which it would be proper to adopt for the tubular bridges which it was proposed to construct. It was made very clear from the experiments that the rectangular form was the best, and that the strength should be concentrated chiefly at the top and bottom of the tube, where the extending and compressing forces would act with greatest energy, and where they must be met. The proportion of the sectional area of the top to that of the bottom to give the maximum strength, was also found to be as 5 to 3 in the case of thin rectangular tubes. It was also made clear that the strength of a tubular beam would be increased if the buckling or crumpling up of the top side could be prevented; and it was known, from previous experiments of Mr. Hodgkinson upon cast-iron pillars, that a given quantity of metal would better resist compression if disposed in a tubular form than if disposed in any other form. Hence it occurred to Mr. Fairbairn, that the compressing strain upon the top of the tube would be more effectually counteracted by disposing the metal in the form of longitudinal tubes than by disposing it in the form of a flat plate. The tube with the corrugated top, tested in the eighth experiment upon rectangular tubes, was made in pursuance of this idea, but eventually it was determined to form the top of the bridge of a series of parallel rectangular tubes or cells, chiefly because that form was more convenient in construction, and better admitted of painting and repairs. The bottom of the tube it was considered advisable to make in the same fashion; and these points being settled, a model tube was constructed, which was nearly identical with one of the tubes of the intended bridge in everything but size. The model tube was 78 feet long, and 75 feet between the supports; 4 feet $6\frac{3}{4}$ inches deep at the middle, and 4 feet $\frac{3}{4}$ inch deep at the ends. It was 2 feet 8 inches wide in the body; but the cellular top was somewhat wider, being 2 feet $11\frac{1}{2}$ inches wide, and the bottom, which was not cellular, but consisted of a flat plate, was of the same width as the top. The cellular top was composed of six longitudinal channels, formed by seven vertical plates $6\frac{1}{4}$ inches deep running longitudinally from end to end of the tube, and having a plate above and another below them extending through the whole length and breadth of the top. The thickness of the plate of the bottom of the model tube was ·156 inches, of the sides ·099 inches, and of the top ·147 inches. The sectional area of the top was 24·024 square inches, of the sides 9 square inches, and of the bottom 8·8 square inches. The weight of the tube was

4·86 tons. Its ultimate deflection was 4·375 inches, and its breaking weight $35\frac{1}{2}$ tons. The tube gave way by tearing asunder at the bottom.

The top plates of the tube having been made a little thicker than was intended, two strips of plate 20 feet long, $6\frac{1}{2}$ inches wide, $\frac{5}{16}$ of an inch thick, and weighing about 4 cwt., were riveted along the bottom of the tube at the centre part. The ultimate deflection then became 4·11 inches, and the breaking weight 43·3 tons. In this experiment the tube got out of shape and collapsed. To obviate this evil for the future, vertical ribs of angle iron were riveted along the sides of the tube internally, at distances of 2 feet apart, and the tube having been repaired, was again subjected to experiment. The ultimate deflection was now found to be 5·68 inches, and the breaking weight 56·3 tons. As, however, in this experiment the fracture occurred, not at the centre of the tube, but at some distance to one side, where the plates were weak, a final experiment was made with the plates decreasing in thickness from the middle according to the proper law. The tube then broke by compression of the cellular top with a weight of $86\frac{1}{4}$ tons.

Mode of Determining the Dimensions proper for the Menai and Conway Bridges.—The strength of any beam larger or smaller than a beam of any given size, but which is increased or diminished proportionally, varies as the *square* of the alteration of its linear dimensions, or more nearly as the 1·9th power in the case of tubular beams, whereas the weight varies as the cube of any linear dimension. A beam, therefore, of twice the length, depth, and thickness of any given beam, will be about four times as strong and eight times as heavy. Taking the weight of the model tube upon which the foregoing experiments were made at 6 tons, the distance between the supports at 75 feet, and the breaking weight of the tube at 60 tons, Mr. Fairbairn calculated that a tube of 400 feet span, such as was intended to carry the railway over the Conway river, would bear a load of 1,704 tons exclusive of its own weight. For since the span of 400 feet is 5·33 times greater than that of the model tube, then $5·33^2 \times 60 =$ 1,704 tons, and the weight of the tube will be $5·33^3 \times 6 = 906$ tons. Now, a given load distributed equally over a beam produces nearly the same strain upon it as half the load applied at its centre, or more correctly the ratio is as 5 to 8. Taking the half of 906 or 453 from 1,704, we have 1,251 tons as the actual load which Mr. Fairbairn considered that the tube would bear exclusive of its own weight.

Mode of Computation by Hodgkinson's Formula for Cast-iron Beams.—Some years before the formation of the Britannia and Conway bridges, Mr. Hodgkinson had ascertained the form of cast-iron beams which gave the greatest strength with the least material; and by the formula derived by Mr. Hodgkinson from these experiments, Mr. Fairbairn concluded that the model tube would bear about 20 tons if it were of cast iron. But it actually bore 56·3 tons in one of the experiments of which the result was not the best; and introducing this correction into the formula, it appeared that a tube six times larger than the model tube, and therefore of 450 feet span, 27 feet deep, and with 460·8 square inches of sectional area of iron at the bottom, would bear 2,018 tons exclusive of the weight of the tube itself. The results obtained by calculating the strengths as the squares, and the weights as the cubes of the dimensions, do not differ materially from the foregoing; and Mr. Stephenson calculated that a tube of 462 feet span, 31 feet deep, and 460 square inches of area at the bottom, would bear 2,469 tons; thus, supposing the tube to weigh 1,200 tons, the breaking weight, when the load was applied at the middle, would be 1,869 tons, exclusive of the weight of the tube itself. Now, a tube which will carry 1,869 tons at the centre, exclusive of its own weight, will, he reckoned, carry about twice this amount, or 3,738 tons, equally distributed over it, exclusive of its own weight; and taking the maximum load to which the bridge would be subjected at one ton per lineal foot, it followed that the bridge, when thus proportioned, would bear eight times the load that could ever be put upon it. One of the tubes of the Conway bridge when completed was tested in the same manner as the model tube, by placing weights upon it and observing the deflections. The result was found to confirm the accuracy of the deductions derived from the experiments upon the model tube. The law followed by the deflections appeared to show that the tube would sustain a load of 2,200 tons equally distributed over it, and exclusive of its own weight, before it broke, and that the ultimate deflection would be 30 inches.

Mr. Hodgkinson's Experiments.— Besides the experiments made by Mr. Fairbairn, a number of experiments upon tubular beams was made by Mr. Hodgkinson, at Mr. Stephenson's desire, and from these experiments results were obtained of great interest in a scientific point of view. Mr. Hodgkinson found that the strength of tubes to resist compression varied greatly with the thickness of the metal of which they were composed. Thus, when the plates composing a tube, compressed in the manner of a pillar, were ·525, ·272, and ·124 inch, the resistances per square inch of section were 19·17, 14·47, and 7·47 tons respectively. Mr. Hodgkinson also found that the power of plates to resist compression varied as the cube, or, more nearly, as the 2·878 power of their thickness. He further found that long-continued impact upon a tubular beam of small size, producing a deflection of less than one-fifth of what would be required to injure the tube by pressure, was completely destructive of the riveting. In large bridges, however, the inertia of the mass will, by resisting the effect of impact, prevent any such injurious effect from taking place.

He also determined, experimentally, that the strength of similar tubular beams was as the 1·9th power of their linear dimensions. Mr. Hodgkinson further made a series of experiments to ascertain if the thickness of the plates of a tubular bridge might be diminished towards the ends, as indicated by theory, and he found that such was the case. The thickness of the plates of the top, bottom, and sides, at any point, was therefore made in the proportion of the rectangle of the segments into which the distance between the supports of the tube was divided at that point, the tube itself being of uniform dimensions throughout; but at and near the supports the thickness was half that of the middle. A further experiment was made to ascertain how far it might be advantageous to stiffen tubular beams with cast iron applied at the top, and it was found that 10 square inches area of cross section of cast iron at the top of the beam balanced 21 square inches of cross section of malleable iron at the bottom of the beam, proving that the cast iron would resist compression more efficiently than the wrought. These investigations, however, though highly important, did not materially influence the configuration of the Conway and Menai bridges, the proportions of which were mainly settled by Mr. Fairbairn from his experiments upon the model tube already described. Experiments were also made, both by Mr. Fairbairn and Mr. Hodgkinson, to determine the strength of tubular beams when laid upon their sides. The purpose of this investigation was to determine the lateral strength to resist storms blowing on the side of the tube, and it was found that the proportions and strengths proper for resisting the vertical strains would also give a lateral strength more than sufficient to withstand any storm to which the tube could be exposed.

Comparative Strains caused by Stationary and Moving Loads.—In proportioning iron beams or girders to bear any given load, the prevailing practice among engineers has heretofore been to give a strength adequate to carry three times the load, if the load be stationary, and twice that strength, or a strength adequate to carry six times the load, if the load be a moving one. When the Conway and Menai bridges were constructed, the precise effect produced upon iron bridges by shifting pressures, vibrations, and concussions consequent upon the passage of a railway train, was by no means accurately known; but since that time those relations have been investigated by a commission appointed for the purpose, and it was one of their functions to ascertain what increase of the statical pressure upon an iron beam or bridge would occasion the same strain as a given velocity of the load. It is clear that, this relation once determined, the statical pressure is all that has henceforth to be considered, and the question of the strength proper for all kinds of constructions is consequently narrowed to the determination of the strength necessary to withstand a certain statical strain, which is greater in an ascertained proportion than that due to the intended maximum load.

Effect of Momentum on the Deflection of a Beam.—If a load be placed upon any long or slender beam propped up in the middle, and the prop be suddenly withdrawn so as to allow deflection to take place, it is clear that the deflection must be greater than if the load had been gradually applied. For the momentum of the weight, and also of the beam itself, falling through the space through which it has been deflected, has necessarily to be counteracted by the elasticity of the beam; and the beam will therefore be bent momentarily to a greater extent than that which is due to the load, and after a few vibrations up and down it will finally settle at that point of deflection which the load properly occasions. It is obvious that such a beam must be strong enough to sustain not merely the pressure due to the load, but also the accession of pressure due to the counteracted momentum of the load, and of the beam itself; and this increased strain is produced in the case of all beams to which a deflecting weight is applied, but is most material in those in which a large and rapid deflection takes place. A rapid deflection increases the amount of the deflection as well as the amount of the strain, as is seen in the cylinder cover of a Cornish pumping-engine, into which the steam is suddenly admitted, and in which the momentum of the particles of the metal put into motion increases the deflection to an extent which the mere pressure of the steam could not produce.

Effect of Deflection on the Amount and Position of the Strain.—If a railway train moving at a high rate of speed be made to descend a steep declivity, the pressure of the wheels upon the rails will obviously be diminished; and if the motion of the train be supposed to be very rapid and the declivity very great, the wheels will leave the rails altogether, and the train will advance after the fashion of a projectile. In like manner, if a rapid train ascends a steep acclivity, the pressure of the wheels upon the rails will be increased. Now, a beam bent by a passing train forms both a falling and rising plane, and on the first half of the beam the strain will be less than that which is due to the load, and on the second half of the beam the strain will be greater than that which is due to the load. The maximum strain therefore, and consequently the maximum deflection, will not be at the centre of the beam, but at a point somewhere between the middle and one end. In order to remedy this inconvenience, the beams of a railway bridge should be made with a slight rise in the centre, so as to form a straight line when deflected by a passing train.

Law of the increased Strain consequent upon Deflection.—The momentum of any moving body being proportional to the square of its velocity, it follows that in the case of a railway train deflected either sideways or upwards by a curve or incline, the strain will be proportioned to

the square of the amount of motion in a new direction given in any specified time; or with any given velocity of the train the strain will be proportional to the square of the amount of the deflection which takes place from a perpendicular or horizontal plane in any given distance along the line.

Effect of the Inertia of Beams.—The mass of matter in a beam first resists deflection by its inertia, and then promotes deflection by its momentum; but whether in practical cases increased mass without reference to strength or weight will, upon the whole, increase or diminish deflection, will very much depend upon the magnitude of the mass, relatively with the magnitude of the deflecting pressure and the rapidity with which that pressure is applied and removed. Thus, if a force or weight be very suddenly applied to the middle of a ponderous beam and then be as suddenly withdrawn, the inertia of the beam will, as in the case of a collision of bodies, tend to resist the force, and thus obviate deflection to a considerable extent; but if the pressure be so long continued as to produce the amount of deflection due to the force, the effect of the inertia in that case will be to increase the deflection. The mass must, under such circumstances, move through a space equal to the deflection, a momentum having been thus acquired which will afterwards expend itself in increasing the deflection. By far the severest strains, however, to which railway structures are habitually exposed arise from the jerks and concussions caused by the imperfect junctions of the rails at the ends, or other similar irregularities of surface, and a large amount of inertia in a beam will enable it to withstand such shocks much better than it could otherwise do. A large inertia compels the train to deviate from the horizontal plane to an extent answerable to the difference of weight of the striking and stricken bodies, so that if the bridge be heavy, it will, under such circumstances, be less deflected, and consequently will suffer a less serious strain.

Law of the Elasticity of Iron Beams.—A bar of iron is usually regarded as a very stiff spiral spring, and it is supposed that it will be compressed or extended equally by equal increments of pressure. This law, however, though nearly true for malleable iron, is not true for cast iron. The compressions and extensions of a bar of cast iron one inch square, and of any length, were found by Mr. Hodgkinson to be represented by the following formulæ :—

For the extension, $w = 13934040 \frac{e}{l} - 290743200 \frac{e^2}{l}$,

For the compression, $w = 12931560 \frac{d}{l} - 522979200 \frac{d^2}{l^2}$.

Here w is the weight in pounds acting upon the bar, e the extension, d the compression in inches, and l the length of the bar in inches. Iron beams alternately deflected and released will be broken in time with a much less strain than that which is necessary to produce speedy fracture. Thus it has been found experimentally, that cast-iron beams deflected by a revolving cam to only half the extent due to their breaking weight will, in no case, withstand 4,000 successive deflections; but 4,000 successive deflections through one-third of the distance due to their breaking weight may be incurred without visible injury. Looking, however, to the various jolts, vibrations, and concussions to which railway structures are exposed, it does not appear that even a strength answering to six times the breaking weight gives an adequate margin for safety in the case of cast-iron beams.

Proportions to be observed in the Construction of Tubular Bridges.—The sectional area of the bottom of a tubular bridge of wrought-iron plates should be to the sectional area of the top as 11 to 12. The breaking weight is then found by multiplying the total area by the depth, by a constant (80), and dividing by the length. The depth of tubular beams of 150 feet span should be about $\frac{1}{13}$ of the span, and the depth of tubular beams of 300 feet span should be about $\frac{1}{15}$ of the span. These rules are empirical, but they are a near approximation to the most approved practice of the present time.

Description of the Britannia and Conway Tubular Bridges.—Having now indicated the manner in which the proportions and configuration of these bridges were arrived at, and having further pointed out the considerations which should influence the design of all railway bridges composed of iron beams, whatever be the subordinate features of their construction, it will be proper to describe briefly the more important features of the Britannia and Conway bridges as they at present stand. The annexed

Fig. 6.

figure represents a portion of one of the tubes seen in perspective. There are two tubes in each bridge, one for the accommodation of the up line, and the other for the accommodation

of the down line. Each tube is rectangular, formed of plates of iron riveted together, and with ribs to support the sides, like the ribs of a ship. The most remarkable feature of the construction, however, is the cellular top and bottom. In all beams which have to be loaded in the centre, it is proper to concentrate the strength as much as possible upon the edges of the beam, or at the top and bottom; and in the case of these bridges this is done by building upon the top and bottom a number of square pipes or pillars joined laterally together and running from end to end of the bridge. The upper pipes sustain a force of compression, the lower of extension; and the function of the sides of the tube is merely to keep these combinations for meeting compression and extension in their proper places. The sectional area of the top and bottom of the tubes may easily be computed by taking the width of each tube, which is 14 feet 8 inches, and the thickness of the plates; but in the model tube, which gave the best results, the sectional area of the top was to that of the bottom as 24 to 22, and this is the proportion commonly employed. There are eight cells or pipes composing the cellular top, each 1 foot 9 inches square. The plates composing the top of the Britannia bridge are $\frac{12}{16}$ at the middle of the bridge, and $\frac{10}{16}$ at the ends of the bridge. The ends of the plates are carefully abutted together, and strips of iron are riveted over the joints. The bottom is composed of six cells or pipes, each 2 feet 4 inches by 1 foot 9 inches; and the upper and lower platforms, by the introduction of partitions between which the cells are constituted, consist each of a double thickness of plates so arranged that the end of each plate comes to the centre of the other, as shown in the accompanying figure. A small plate covers each joint, and as it was important not to weaken the bottom of the tube by the rivet holes running across it, the rivets are arranged in longitudinal rows, each a considerable distance from the other, and they act as cogs or steady pins in keeping the plates together. By this expedient the longitudinal cohesion of the bottom is better maintained; and the strength of each tube approximates to what it would be if formed out of a solid piece of iron, instead of being built up of riveted plates. The thickness of the plates forming the upper and lower platforms of the bottom is $\frac{9}{16}$ at the middle of the tube, and $\frac{7}{16}$ at the ends. The vertical plates are $\frac{9}{16}$ at the middle, and $\frac{8}{16}$ at the ends. The sides of the tube are $\frac{8}{16}$ at the middle of the bridge, increasing to $\frac{10}{16}$ where the bridge rests upon the piers; for as the ends of the tube have to sustain the whole weight, they require to be made very strong and stiff to retain them in shape. To impart increased stiffness at the ends of the tubes, strong cast-iron frames are introduced within them, and an arrangement of rollers is provided beneath the ends of the tubes to enable the metal of the tubes to expand or contract with changes of temperature.

Fig. 7.

The tubes of each bridge were built in the same manner as an iron ship, adjacent to the place where they had to be erected. A wooden platform or quay was erected upon the shore, upon which a tube was built, and stone supports were subsequently erected at the ends, upon which the tube when completed was made to rest. The timber platform was then cleared away so as to enable a number of boats or pontoons to be floated beneath the tube, and these rising with the tide lifted the tube. The floating mass was then drawn by ropes across the stream, and the ends of the tubes were rested in shelves left in the masonry of the piers, by which the tube had to be sustained. On the tops of the piers hydraulic presses were set, from which chains descended to the ends of the tube, and by putting these hydraulic presses into operation the tube was raised up a small distance, and so soon as it was raised sufficiently above the shelf the intervening space was built up. Another lift was then taken, and so on, the masonry following up the tube as it ascended, until it reached the level of the top of the piers. In the Britannia bridge there are four spans; and the tubes of each span are joined together at the ends, so as to form one long tube for each line of railway. The effect of thus joining the ends of the tubes is virtually to diminish the span, for the tube takes a contrary flexure where it passes over the piers, and if a line be drawn down the side of the tube where these contrary flexures meet, it will be found that the tube might be cut through that line without weakening it at all.

Chepstow and Saltash Tubular Bridges.—Tubular bridges of a construction very different from that of the Conway and Britannia bridges have been erected by Mr. Brunel, for carrying the South Wales Railway over the river Wye, at Chepstow, and also at Saltash. These bridges have a nearer resemblance to a suspension bridge than to a hollow beam: but instead of the heads of the towers being held back by chains, as is usual in suspension bridges, they are kept asunder by cylindrical struts of wrought iron, and rods descend from the tops of the towers, which are also of iron, to support the platform of the bridge. [VIADUCT.] The limits of this article, however, leave no room for any detailed description of these and other tubular bridges which have been constructed since the Conway and Menai bridges were projected. (For further information on the subject, see Mr. Fairbairn's *Account of the Construction of the Britannia and Conway Tubular Bridges*, and the *Report of the Commission appointed to inquire into the Application of Iron in Railway Structures*; Jeaffreson and Pole, *Life of Robert Stephenson*, vol. ii.

Tubular Surface. In Geometry, the envelope of a sphere of constant radius whose

centre describes a given curve—the *axis of the tube*. These surfaces have been most instructively treated by Monge in his *Application de l'Analyse à la Géométrie*. Two successive generating spheres intersect in a circle, of the same diameter as the sphere, whose plane is normal to the axis. The surface itself may be considered as the *locus* of this circle, which by Monge is termed the *characteristic*. [CHARACTERISTIC OF AN ENVELOPE.] The successive characteristics by their intersection form an *edge of regression* or *cuspidal edge* on the surface. If $x=f(a)$, $y=\phi(a)$, $z=\psi(a)$ be the equations of the axis, and a be the radius of the generating sphere, the equation of the latter in one of its positions, individualised by the parameter a, will be

$$F(x,y,z,a)=[x-f(a)]^2+[y-\phi(a)]^2 \\ +[z-\psi(a)]^2-a^2=0,$$

and the equation of the tubular surface will result from the elimination of a between the equations $F=0$ and $\frac{dF}{da}=0$, which two equations, in fact, represent the *characteristic* corresponding to the value of a. The equations of the *cuspidal edge* are obtained by eliminating a between $F=0$, $\frac{dF}{da}=0$, and $\frac{d^2F}{da^2}=0$. For further details the reader is referred to Monge's work.

Tubularia. The name of a genus of Corallines with simple or branched horny tubes, from the extremities of which the polypes are protruded: these have two rows of tentacles, of which the external is expanded in a radiated manner, the internal one being raised into a tuft.

Tubulibranchians. The name of an order of hermaphrodite gastropodous Molluscs, comprehending those which have the shell in the form of a more or less irregular tube in which the branchiæ are lodged.

Tubulicoles. *Polypes à Tuyaux.* A name applied by Cuvier to a family of Polypes, including those which inhabit tubes of which the axis is traversed by the gelatinous flesh, and which are open at the summits or sides to give passage to the digestive sacs and prehensile mouths of the polypes.

Tubuliflore (Lat. tubus, and flos, *a flower*). One of the three large suborders into which De Candolle divides the *Compositæ*. It comprises the *Corymbiferæ* and *Cynarocephalæ* of Jussieu, including those Composite plants which have all or at least the central florets of each head regular and tubular.

Tucan. [RAMPHASTOS.]

Tuesday. In the Calendar, the third day of the week, named after the god Tuisco; whence the astronomical symbol is the same as that for the planet Mars. [TYR.]

Tuesite. An amorphous mineral of a bluish or milk-white colour, and closely allied to Halloysite, China Clay, and Lithomarge. The name is derived from *Tuesa*, the Latin name for the river Tweed, in the New Red Sandstone of whose banks the mineral is found.

Tufa (Ital. tufo, *porous ground*). A name applied in Italy to certain porous loose rocks, sometimes consisting chiefly of calcareous matter deposited from water containing much carbonate of lime in solution, and sometimes of fine powdery volcanic dust cemented more or less completely by the infiltration of water, but generally loose and spongy. This dust consists of material erupted from volcanoes, and under the microscope has sometimes been found to contain large quantities of the silicious cases of infusoria.

The first-named variety is called *calcareous tufa*, the last-named *volcanic tufa* or *tuff.*

Volcanic Tufa is the material under which Pompeii was buried. Similar materials have been deposited in places where there are no other indications of volcanic action, and occur among rocks of all ages.

Calcareous Tufa when consolidated passes into Travertine.

Tuff. [TUFA.]

Tug. A ship used for the purpose of towing other vessels.

Tugendbund (Ger. *union of virtue*). A patriotic association formed in Prussia after the treaty of Tilsit in 1807. Its object was to prepare the people of that country by moral instruction and discipline for better times. It was abolished at the instigation of the French; but its spirit survived, and it had great effect in promoting the national war against Napoleon in 1813.

Tuisco. [TYR.]

Tulip-tree. The common name for the North American *Liriodendron tulipifera.*

Tulip-wood. The striped rose-coloured wood of *Physocalymma floribunda.*

Tulipa (Pers. thoulyban, *a turban*). A genus of *Liliaceæ*, consisting entirely of bulbous plants. *T. Gesneriana*, the Tulip of gardens, has been a favourite object of the florist's care for three centuries. Gesner, who first made it known by a botanical description and figure, saw it in A.D. 1559 at Augsburg, the seeds having been brought from the Levant. It was at that time known in Italy under the name of *tulipa*, given to it on account of its resembling a turban, *tulbent*. In the middle of the seventeenth century, Tulips became the object of an unprecedented trade, by which their price rose above that of the most precious metals. The high prices paid for bulbs, amounting in some instances to 2,500 and even 4,600 florins, did not, however, represent the estimated value of a root, since these large sums often changed hands without any transfer of property. Bulbs were bought and sold without being seen, and even without being in existence. The tulip is still extensively cultivated, there being many hundreds of named varieties.

Tullius, Servius. [SERVIUS TULLIUS.]

Tumble Home. The term describing the falling or bending inwards of the upper timbers

of the ship's side. It is the function of the beams to counteract this tendency.

Tumbrel (Fr. tombereau). A covered cart employed to convey ammunition, the tools of miners, pioneers, &c. The term is now almost obsolete.

Tumuli. [Barrows.]

Tun (A.-Sax. tunna). A measure of capacity. The English tun contains 252 gallons, or 4 hogsheads. [Ton.]

Tune (Ital. tuono, Fr. ton, Gr. τόνος, from τείνω, *to stretch*, akin to *thunder*). In Music, a tune signifies an air or melody. In other words, it is a certain succession of different single sounds arranged according to art. The word also refers to accuracy of intonation; a voice or instrument is said to be *in tune* when all its notes are correctly intoned, and *out of tune* when they are intoned incorrectly. *To tune an instrument* is to adjust its strings or other sounding elements so as to give correct intonation, or make it play in tune.

Tungstates. Compounds of *tungstic acid*. Muslin and similar textures imbued with a solution of tungstate of soda are to a great extent rendered incombustible.

Tungsten (Swed. tung sten, *heavy stone*). The ores of this metal are the native tungstate of lime, and the tungstate of iron and manganese; the latter mineral is known under the name of *Wolfram*. Tungsten is a white, hard, and brittle metal, very difficult of fusion, and having the high specific gravity of 17·4. Heated to redness in the open air, it burns into the *peroxide*, or tungstic acid. The atomic weight of tungsten is 92, and the tungstic acid consists of 1 atom of metal and 3 atoms of oxygen ($8 \times 3 = 24$), and is represented by the equivalent 116. This metal is sometimes called *Wolframium*. It is generally represented by the symbol W.

It forms two oxides: binoxide WO_2 and teroxide or anhydrous tungstic acid WO_3; an oxychloride WO_2Cl; two sulphides WS_2 and WS_3; and two phosphides W_3P_2 and W_4P. [Wolfram.]

Tunic (Lat. tunica). A garment worn by the ancient Romans of both sexes, under the Toga and next to the skin. It was generally of wool, of a white colour, and it reached below the knee. The senators wore their tunics with a broad stripe of purple sewn on the breast; the equites had narrow stripes: hence the epithets *laticlavii* and *angusticlavii*, applied respectively to these orders.

Tunicaries (Lat. tunica). The name of a class of Acephalous Molluscs, comprehending those in which the exterior covering is uncalcified, soft, and elastic: it is equivalent to the *Ascidies* of Savigny, and the *Acephales sans Coquilles* of Cuvier.

The following is the modern classification:—

Order: *Saccobranchiata*.

Fam.: Botryllidæ, Clavellinæ, Ascidiadæ, Peloniadæ, Pyrosomidæ.

Order: *Tæniobranchiata*.

Fam.: Salpidæ.

Tunkers. [Dunkers.]

Tunnel (Ger.; Fr. tonnelle). A horizontal perforation in the earth, usually made to conduct a railway or canal through a mountain or other elevated ground, or under a river or other tract of water which cannot conveniently be bridged. One of the most interesting works of this kind is the tunnel carried under the Thames, to connect the lower parts of London lying on each side of the river with one another by a convenient roadway, without involving the necessity of building a bridge, which in that spot would interfere with the navigation of the river. Tunnels of much greater length and difficulty have, however, since been constructed; and it is now proposed to connect the French and English systems of railway by a tunnel carried beneath the British Channel. In the English railways, there is on an average one mile of tunnel for every 124 miles of railway. Tunnels are generally lined with brick or stone, but sometimes the sides and top consist of the naked rock, and in such cases there is occasionally considerable leakage in wet weather through cracks in the roof.

The first task in the construction of a tunnel is to fix the vertical plane which it shall follow, and this is done by the aid of a transit instrument, usually about thirty feet focal length, set in a raised wooden structure or observatory placed on the highest ground in the centre of the length, and so far raised above the surface that the view may not be obstructed by the earth raised through the working shafts. Tunnels are almost universally straight, but with a sufficient declivity towards each end to facilitate drainage, crooked tunnels being not only more difficult to construct, but a source of danger in working the line, from the inability of the engine-driver to see ahead. The centre line of the tunnel having been carefully ranged, the next procedure is to sink trial shafts, which are sometimes made sufficiently large to be used as working shafts, and through these shafts and through the ends of the tunnel the excavated earth is removed. When the shafts are completed, the *heading* or *adit* is commenced, which may be described as a small square tunnel, the sides of which are supported by stout poles and boards, and which is afterwards enlarged to the dimensions which it is required that the tunnel shall have. The top of the heading is usually placed so much above the intended soffit of the arch of the tunnel as to admit the proposed thicknesses of brickwork and of the crown bars, packing and poling boards, together with an allowance of several inches for the settlement of the timber, which is sure to take place when more of the excavation is made, and before the brickwork can be inserted to take the weight. When the heading is driven, it is widened at the top along one side, to form a shelf on which a crown bar may be laid lengthways. Other bars are then similarly introduced, which are strutted from the ground and from one another, and poling boards overlapping one another are then

introduced behind the bars, the whole forming a short length of rough wooden tunnel within which the brick tunnel is built up as the work advances. The length of tunnel built at a time is usually about twelve feet.

The most remarkable tunnel yet undertaken is the tunnel through Mont Cenis, as it is usually called, although it is in fact several miles from that pass. It is intended to connect the French and Italian systems of railways. This tunnel is 7½ miles long, through rock. At Modane, on the French side, it is 25 feet 3¼ inches wide at the base, and 26 feet 2¾ inches wide at the broadest part, by 24 feet 7 inches high, the arch being a semicircle nearly. At Bardonnèche, on the Italian side, the height is increased 11¾ inches. At the French end, the tunnel is lined with stone, and at the Italian end the sides are of stone and the arch of brick. From the French end to the middle the gradient is 1 in 45½. The other end slopes from the centre downward with a declivity of 1 in 2,000 to enable the water to run off. When the tunnel is completed, it is expected that there will be a constant draft of air through it from north to south. The tunnelling is effected by blasting the rock with gunpowder, but the holes in which the gunpowder is deposited are bored by a machine, driven by compressed air, which, in twenty minutes, pierces a hole 1¼ inch diameter and 3 feet deep, which would have taken two miners two hours to bore. The machine consists of two main parts: the first a cylinder for propelling the borer against the rock, and the second a rotatory engine for working the valve of the striking cylinder, for turning the borer on its axis at each successive stroke, and for advancing or retiring the striking cylinder as occasion requires. A movable framework is arranged for carrying eleven such machines, any one of which may be worked at any angle—allowing the free action of each in a gallery ten feet square. Each machine gives 250 blows per minute. The pressure of air on the piston is 216 lbs. per square inch, and the length of the stroke varies from 2 inches to 7½ inches. The cost of each machine is about 80*l.* The average advance of the tunnel at the beginning was at the rate of four or five feet per day, but latterly the rate of progress was greater. The speed of tunnelling by these machines is about three times greater than by tunnelling in the old way, but the cost per foot forward is also somewhat greater. The ventilation of the workings is maintained by the escape of compressed air from the machines. The air is compressed by two machines at the outside of the tunnel, of which one operates on the hydraulic ram principle, and the other is a compressing pump. The tunnelling is estimated to cost 210*l.* per mètre. The tunnel of Mont Cenis is a mile in depth below the top of the mountain.

For a history of the Thames Tunnel, the reader is referred to Beamish's *Life of Sir M. I. Brunel*.

A boring machine for tunnels, with an outside cutter and central hole for powder, was made at Boston, U.S., and used in the Hoosie tunnel in 1852. Gay has a patent for the same thing, and other patents for similar contrivances have since been taken out. A good account of the mode of constructing ordinary tunnels is given in Simms' work on *Practical Tunnelling*.

Tunny. [THYNNUS.]

Tupa (its Chilian name). A genus of *Lobeliaceæ*, consisting of tall herbaceous plants or undershrubs, with unbranched stems, alternate lance-shaped leaves, and many-flowered leafy racemes. They are natives of Peru, Chili, and the West Indies. *T. Feuillei* yields an acrid poison in Chili, where the root is chewed to relieve the pain of decaying teeth. So acrid is this plant, that, according to Feuillée, even the odour of the flowers will cause excessive vomiting, and if taken internally, or even applied to the skin, violent inflammation and pain are produced, sometimes resulting in death.

Tupelo or **Tupelo-tree.** An American name for *Nyssa*.

Turanian Languages. In Philology, a name applied to languages which have reached the second stage of grammatical developement. In the first or radical stage, every word or part of a word is felt to express its own radical meaning, as in Chinese, which has no formal distinctions between a noun, a verb, an adjective, an adverb, or a preposition. As soon as the word used as a suffix loses its etymological meaning, and becomes a mere sign of derivation or of case, the language enters into the second or agglutinate stage which marks the dialects of the Turanian family. This family comprises by far the largest number of languages. The languages of the third or inflexional stage, spoken by Aryan nations, have all unquestionably passed through the agglutinate stage, but the component parts have in these so coalesced that it becomes in numberless instances very difficult to distinguish the root from the modifying element. Such a grammatical system would be wholly useless for the needs of a nomadic population, which requires that their language should be intelligible to many who may have only the slightest intercourse with each other. 'It requires tradition, society, and literature to maintain words and forms which can no longer be analysed at once. Such words would seldom spring up in nomadic languages, or, if they did, would die away with each generation.' Thus the Sanscrit or even the Latin inflexion of the verb as-mi, sum, *to be* [LANGUAGE], might be intelligible to nomads, because, for the most part, it preserves the root in a form in which it may easily be distinguished from the pronominal suffix; but the English inflexion of the same verb would convey to them no meaning.

The idea which a Turanian 'connects with a plural is that of a noun followed by a syllable indicative of plurality: a passive is with him a verb followed by a syllable expressive of suffering, or eating, or going.' Hence these

languages are especially liable to the changes produced by dialectical regeneration, until the tribes attain a political organisation. The dialects then assume a traditional form, as is the case with the Hungarian, Finnish, Tamil, Telugu, &c.

The Turanian family of languages consists of two great divisions—the *northern* and *southern*.

'The northern is sometimes called the *Ural-Altaic* or *Ugro-Tataric*, and it is divided into five sections: the *Tungusic*, *Mongolic*, *Turkic*, *Finnic*, and *Samoyedic*.

'The southern, which occupies the south of Asia, is divided into four classes: the *Tamalic*, or the languages of the Dekhan; the Bhotîya, or the languages of Tibet and Bhotan; the *Taic*, or the dialects of Siam; and the *Malaic*, or the Malay and Polynesian dialects.' (Max Müller, *Lectures on Language*, first series, viii.)

The Basque language, still spoken in the Spanish and French Pyrenees, is a form of speech which in grammatical construction resembles the Turanian family of languages, while it is surrounded by inflexional dialects, with none of which it exhibits the slightest affinity; but the evidence of inscriptions on coins or monuments, together with the names of cities, rivers, and mountains, seems to prove that the Escuara, or Basque, now spoken only by the insignificant tribes who call themselves Escualdunac, was once the language of a race spread over the whole Spanish peninsula; but the language itself further points to a time when the only languages spoken throughout Europe (so far as it was inhabited) belonged to the class of which specimens are still seen in the Basque and Finnic dialects. (Michel, 'Le Pays Basque,' *Edin. Rev.* April 1864, p. 373; *Quart. Rev.* April 1866, p. 419 &c.) [Agglutinate Languages.]

Turanira Wood. The timber of the Bastard Bully-tree of Guiana, which is probably a species of *Mimusops*.

Turban (Arab.). The usual head-dress of the Turks, Persians, and most other Eastern nations. It varies in form in different nations, and in different classes of the same nation. It consists of two parts: a quilted cap, without brim, fitted to the head; and a sash, scarf, or shawl, usually of cotton or linen, wound about the cap, and sometimes hanging down the neck. The sultan's turban contains three heron's feathers, and is ornamented with diamonds.

Turbine (Lat. turbo, *anything that turns round*). A species of horizontal water wheel, formed with inclined vanes resembling those of a windmill or smoke jack, and put into revolution by a stream of water passing through it. There are various forms of turbine, all constructed on the same general principle, but differing in the details. A good turbine will give a performance of 80 per cent. of the theoretical power of the water, being about the same as that which is obtained from a good overshot water wheel.

By a patent of 1849, Mr. Ruthven applied this principle, in a reversed sort of way, i.e. as a centrifugal pump, to the propulsion of ships; and after some minor successes, the British Admiralty launched the iron-clad gunboat Waterwitch, of 778 tons, in 1866, to test the efficacy of the system. A large turbine is rotated by powerful machinery. Centrifugal force drives the water contained in it at the rate of 300 tons a minute, out of nozzles in the side of the ship, while water rushes through valves in the bottom, to supply the place of that which is expelled. The nozzles open backwards or forwards by a double valve, motion being imparted to the vessel by the direct action of the water driven out. The nozzles are amidships; and as they can be worked independently, the steering power is very great, even without reference to the rudder. Thus far, the Waterwitch is but an experiment; the results, however, of several trials show that this mode of propulsion is as economical at the least as screw or paddle, while there are some other points in its favour, as, for instance, the extraordinary facility for pumping water out of the ship.

Turbo (Lat.). The name of a Linnæan genus of the *Vermes Testacea*, characterised by having a shell of a regular turbinated form with an entire and rounded mouth. The species grouped together by this specific character form a family of pectinibranchiate Gastropods in the system of Cuvier, which is united by later conchologists with the family Trochidæ.

Turbot (Fr.). The best, and, excepting the halibut, largest of our flat fishes: it is the type of the subgenus *Rhombus* of Cuvier.

Turdus (Lat.). The Linnæan generic name of the passerine birds which have the beak conical, sub-compressed, and arched, but not terminally hooked, nor so deeply notched at the margin as in the shrikes. They are frugivorous as well as feeders on insects, worms, and molluscs. The genus includes our blackbirds and thrushes, with the mocking-birds of North America, and various exotic birds now ranked as subgenera.

Turf (A.-Sax. tyrf). The surface of grass lands, of a smooth and uniform texture, covered with pasture grass. The term is also sometimes applied to Peat cut out of bog.

Turgite. A compact reddish-brown mineral, composed chiefly of hydrated peroxide of iron, found in the Turginsk copper mines in the Ural.

Turk's-cap. The name applied to *Melocactus communis*; also to *Lilium Martagon*.

Turkey. [Meleagris.]

Turkey Red. A fine and durable red dyed upon calico and woollen cloth; the colouring matter used in its production is madder, but the process for producing it in perfection is tedious and complicated. (Bancroft *On Permanent Colours*.)

Turlupins (a word of which no satisfactory derivation has been found: Ducange, *Glossary*). In French Ecclesiastical History, one of the numerous popular by-names by

which the sectaries of the fourteenth century, *the* precursors of the Reformation, were distinguished: called elsewhere BEGHARDS, BEGUINS, LOLLARDS, PICARDS, &c.

Turma (Lat.). In the Roman legion, a company of horse, ten of which formed the whole cavalry attached to each legion. Each *turma* consisted of thirty horsemen, divided into three decades or decuries, representing severally the three equestrian tribes, Ramnenses, Titienses, and LUCERES; and each commanded by a *decurio* with an *optio* or lieutenant.

Turmeric (Ital. turtumeglio). A medicinal and tinctorial substance obtained from the root of *Curcuma longa*. It forms one of the chief ingredients in the preparation of Indian curry-stuff or curry-powder, to which it imparts its yellowish hue.

Turn (A.-Sax. tyrnan, Ital. torno, probably akin to Gr. τόρνος). In Music, a grace thus marked ~; indicating that the note above it, one degree higher, must be struck before it shortly, then passed quickly through the note itself and *turned* from the note a degree below into the note itself, over which the mark is placed.

Turn-table. A large circular plate of metal set on a railway on the level of the ground, so that a locomotive or railway carriage may run upon it, and by then turning the plate round, the carriage may be delivered on to another line of rails than that from which it was received. [RAILROADS.]

Turnbull's Blue. A modification of *Prussian Blue*. [PRUSSIAN BLUE.]

Turner's Cerate. This is the *calamine ointment* of the *Pharmacopœia*. The modern zinc ointment prepared with oxide of zinc and hog's lard is a good substitute for it: it is a mild drying ointment.

Turner's Yellow. The fused oxichloride of lead, in fine powder: it is the basis of a yellow oil colour used in coach-painting: it is also called *patent yellow*, and *Cassel yellow*.

Turneraceæ (Turnera, one of the genera). A small order of hypogynous Exogens, consisting of tropical herbs or undershrubs, chiefly American or African, with alternate leaves, and yellowish or blue axillary flowers. They agree with *Passifloraceæ*, *Homaliaceæ*, and some others in their petals alternating with the lobes of a campanulate or tubular calyx, and in their one-celled ovary with three parietal placentas. They are chiefly remarkable for their forked styles.

Turnerite. A yellow or brown mineral containing alumina, lime, magnesia, and a small quantity of iron-oxide. It is found at Mount Sorel in Dauphiny, and was named after Mr. Turner, in whose cabinet it was first noticed.

Turning Lathe. An instrument for rotating hard materials, such as wood or iron, round a horizontal axis, to the end that a fixed cutting edge, such as a chisel, may be applied to them, their external surface being thus made to assume a true circular form. The turning lathe is an instrument of great antiquity, and is nearly allied in its character to the potter's wheel, only that in that instrument the axis is vertical. In the East, turning lathes do not usually give a continuous rotation to the objects placed in them, but the objects are first rotated in one direction and then in the other, by means of a bow, the string of which is passed once or twice round the material to be turned, the bow being moved backward and forward by one hand while the chisel is held by the other, aided usually by the toe. The introduction of the treadle, and crank and fly-wheel, to give continuous motion to the spindle of the turning lathe, was a valuable improvement, the author of which is not known; but it was in imitation of this arrangement that Watt introduced the crank and fly-wheel into the steam engine. Turning lathes are now made, for many purposes, of very great size, and large lathes are almost invariably driven by a steam engine. Such lathes are also set upon an iron bed, upon which the rest which holds the cutting tool may be drawn along gradually by a screw; and as the sliding surfaces are made very true, the article placed in the lathe is turned with corresponding accuracy. If the cutting point is drawn forward in a straight line, the article in the lathe will have a truly cylindrical form; but if the cutting point be made to move round a vertical axis passing through the horizontal axis of the lathe, the article will assume a globular form; or if the cutting point be gradually drawn back while it is at the same time moved onwards, and be again restored to its former depth, the article, instead of being truly cylindrical, will be bellied in the middle. The *chuck* of a lathe is a plate which may be screwed upon the rotating spindle, and to which objects requiring to be turned may be fixed. But the chuck may be so constructed, that instead of simply rotating with the spindle, it will move in and out at the same time. In this case it is called an *eccentric chuck*, and by its aid such figures may be traced on the surface of the work as are seen on the backs of watches. [ROSE ENGINE.]

Turnip (A.-Sax. næpe, Lat. napus). A well-known garden vegetable and agricultural root-crop, furnished by the many varieties of *Brassica Rapa*. The Swedish Turnip is the *Brassica campestris rutabaga*.

Turnip-fly. As different insects prey, in the larva state, upon the leaves of the growing turnip, the most destructive, and consequently the most important and interesting of these, will be noticed under the present head. They are the turnip-flea, as it may be called from its power of agile leaping (*Haltica nemorum*), and the turnip-fly (*Athalia centifolia*). The turnip-flea belongs to a genus (*Haltica*) of minute Coleopterous insects, of the section *Tetramera*, and family *Galerucidæ*; in which genus the species are all remarkable for the large size of the femora or thighs of the hindmost pair of legs. The species in question does not exceed the twelfth of an inch in length; it is of an oval form, with the elytra of a greenish tinge, each ornamented with a broad longitudinal stripe of a pale brimstone colour; but there

are other species of the same genus, perhaps equally destructive, and not characterised by the longitudinal elytral bands. The perfect insect shelters itself in the rough uncultivated margins of fields, feeding upon the hedge-weeds; and appears to be ready at any time, provided the weather be warm, to commence the work of destruction on the young turnip shoots. Late sowing of the turnip seed does not therefore obviate the attacks of the *Haltica*. The first precaution obviously is to clear away all the weeds in the neighbourhood of the turnip grounds that may afford food or shelter to the little enemy. When the turnip-flea has made its appearance in the crop, the ground should be dusted with quicklime, and this should be repeated as often as rain or wind beats it off, and the flea reappears. The other enemy to the turnip (*Athalia centifolia*) belongs to the order *Hymenoptera*, and family *Tenthredinidæ*, or saw-flies.

Turnsol. [Litmus.]

Turnsole. A purple dye-drug, the inspissated juice of *Crozophora tinctoria*.

Turpentine (Gr. τερέβινθος). A resinous exudation, which flows from incisions made in the stem of trees of the Pine family. Thus, Boston Turpentine is an American Turpentine, obtained from *Pinus palustris* and *P. tæda*; Bordeaux Turpentine is a resin obtained from *Pinus Pinaster*; Strasburg Turpentine is a resin obtained from *Abies pectinata*; and Venetian Turpentine is an oleo-resin obtained from *Abies Larix*, the common Larch. Chio, Scio, or Cyprus Turpentine comes from a different source; it is a limpid fragrant balsamic resin yielded by *Pistacia Terebinthus*.

Turpeth, Turpith, or Turbith Mineral. The yellow basic sulphate of mercury ($3HgO,SO_3$), so called from its yellow colour, which resembles that of the root of the *Ipomæa* or *Convolvulus Turpethum*.

Turquois. A bluish-green stone much used in jewellery. It is an amorphous form of hydrated phosphate of alumina. The finest kinds of Turquois are obtained from Persia and Arabia; but it is also found in Saxony. The name, according to Jameson, originated in the circumstance of the first specimens having been brought from Turkey.

For a full account of this stone (the Oriental Turquois), and the Occidental (Bone Turquois or Odontolite), see Bristow's *Glossary of Mineralogy*.

Turret Ship. A species of iron-clad war vessel, in which the guns are carried in one or more iron turrets, which may be rotated either by hand winches or by a steam engine, so that the guns may be fired in any required direction. There are two varieties of turret ship, of which the earliest and best is that which was invented by Captain John Ericsson of New York. The other variety—which in many of its features resembles the plan of Ericsson—is known as the system of Captain Cowper Coles, and this system has been adopted to some extent in the British navy, while the American navy has adopted the system of Ericsson, usually called the *Monitor system*, from the Monitor, the name of the first vessel of this kind that was constructed. The American Monitors have this great feature of superiority over Captain Coles' turret ships, that they are so provided with artificial ventilation that all the orifices in the deck may be hermetically sealed except those provided for the admission of the air which enters through high shot-proof trunks, which trunks, while admitting the air, exclude the water. They may thus be made much thicker in the sides than other vessels which depend for their ventilation upon open hatches or gratings, as the sides may without risk be made very low. Usually only a portion of the saving effected in the weight by lowering the side is expended in increasing the thickness of the armour, the residue being expended in increasing the weight of the gun and the power of the engine. But inasmuch as in the Monitor system the area of target is made a minimum, the thickness of armour or the power of engine and gun may be made a maximum with any size of vessel. Much doubt was at one time entertained by some, whether vessels with the low sides of the Monitors would be safe at sea. But such doubts have now been extinguished by experience; and it is plain, that as the Monitor construction combines the greatest power of offence with the greatest power of resistance, it constitutes the most formidable species of war vessel known at the present day.

History of Turret Ships.—The first design of a turret ship was produced by Ericsson, who, on September 26, 1854, forwarded to the Emperor Napoleon a drawing of an iron-clad screw vessel with a revolving iron-clad cupola or turret protecting a heavy gun. The turret was placed in the centre of the ship, and was hung on a central spindle turned by a steam engine, as in the Monitors, while the rudder and screw were protected, as in the Monitors, by projections of the deck. But although the design was not produced until 1854, during the Crimean war, Ericsson had been giving the subject his attention since 1826. In a letter to the *Times*, dated April 5, 1862, Captain Coles says the idea of building impregnable vessels first occurred to him in the year 1855, and that towards the latter part of that year he had a rough model of such a vessel made by the carpenter of the Stromboli. But Captain Coles' first idea was limited to the construction of a raft, with a gun placed upon it and protected by a shield. Under this arrangement, the raft had to be moved in order to point the gun. This crude idea was submitted to the Admiralty, but met with no encouragement there. Subsequently, Mr. Brunel suggested to him the expediency of placing the gun and its protecting shield upon a turn-table. In March 1859, Captain Coles produced drawings of a shield fitted with turntables; and in December 1860, he published drawings of his gun-shield and revolving plat-

form in *Blackwood's Magazine*. These shields are each composed of a heavy framework of timber, covered by 4½-inch armour plates, and each of them forms the frustum of a cone 15 feet in diameter in the largest part, and 6½ feet high. Within this cramped conical apartment, two breech-loading Armstrong guns are mounted, which it is proposed to fire with a service charge of 12 lbs. of powder. It was with conical cupolas on this plan that Captain Coles first proposed to fit the Royal Sovereign. But meanwhile the success of the Monitor in America caused the sloping shields to be abandoned, and the Ericsson form of turret to be substituted, retaining, however, the turntable rollers, which involve several features of serious disadvantage. What these are, it will now be proper to explain.

Difference between Ericsson's and Coles' Turret Ships.—In Ericsson's turret ships—or Monitors, as they are usually termed—two heavy guns are placed in a central turret, though in some cases two turrets are employed, each carrying two guns. In the Puritan and Dictator class of Monitor, the iron on the sides is 10½ inches thick, backed by over 3 feet of oak, and the turret is of iron 15 inches thick. Nevertheless, the Dictator is a vessel of much less displacement than the Bellerophon in the English navy; and if her displacement were made the same, then the thickness of the iron of the turret could be increased to 24 inches, and the thickness of the side armour and the power of the engine could also be augmented. In the Royal Sovereign the thickness of the side armour is only 5½ inches. In Ericsson's Monitors, the turret is attached to the vessel by means of the central spindle, and the bottom edge of the turret rests water-tight upon a metal ring let into the deck. In Coles' vessels, the turret passes through a great hole in the upper deck, and rests on rollers set on the deck beneath. A large annular opening is left round to permit its free rotation, which is accomplished by men working winch handles below the deck, and as it is difficult to make this great orifice water-tight, and as there is no artificial ventilation for the avoidance of open stoke-hole hatches, the sides of the ship must be made as high as those of any ordinary vessel, while, as the area to be protected is large, the armour has to be correspondingly thin to enable the vessel to carry it. If, moreover, the turret, from the impact of heavy shot, should cease to be quite round, the gearing employed to turn it will no longer work; or if shot and shell be broken up on the face of the turret, fragments will be projected into the annular space between the turret and the deck, which will jam and hinder its rotation. The donkey engines which rotate the turret of the Dictator, exert a force of 70,000 lbs. applied at its circumference; and the movement of a man's finger, acting upon the valve of the engines, will suffice to rotate the turret in either direction.

Many vessels have been constructed in America on the plan of the Monitor, and, having been subjected to the severest tests in actual war, have been found to be seaworthy, shot-proof, and efficient in every respect. Most of the Monitor vessels are fitted with 15-inch cast-iron guns; but the Puritan is fitted with 20-inch cast-iron guns, and the American government now contemplates the construction of cast-iron guns of 25-inch bore, and throwing a shot of a ton weight. Ericsson's 13-inch wrought-iron gun is built up of longitudinal bars welded together, and over this barrel washers of plate iron three-eighths of an inch thick are forced by hydrostatic pressure. This gun has sent a ball to a distance of 5 miles with a charge of 70 lbs. of powder, and it is reckoned that it could not be burst even if filled with powder to the muzzle. The Kalamazoo class of American Monitors is fitted with two screws, and the armour on the sides is 14 inches thick.

Subordinate Features of Monitor Vessels.—The presiding principle in the design of Monitor vessels is the principle of concentration. The armour is collected into a narrow belt of great thickness, and into a single turret, while the guns are collected into two pieces of great size. On the Dictator, the armour belt is 6 feet deep, of which only 16 inches appears above the water. This armour constitutes a belt 4 feet thick, applied to the outside of the ship, and consequently projecting several feet beyond the stem, this belt being prolonged at the stem and stern, to form a ram at each end, and also to protect the rudder and the screw from shot. The turret is placed in the centre of the ship: it is 24 feet in internal diameter, and 9½ feet high, and to the top of it a bell mouth 3½ feet high is attached to throw off any water that may dash against it. The top of the turret is covered with strong bars of iron, set about two inches apart, over which are spread perforated iron plates 1 inch thick. The turret is for the most part built up of thicknesses of inch plate riveted together, but the central part is formed of thick slabs of wrought iron, the collective thickness of the whole being 15 inches. The guns are two of Rodman's 15-inch guns, which can burn 60 lbs. of powder. The pilot house is a cylindrical iron chamber, 8 feet diameter, 7 feet high, and 13 inches thick, set on top of the central pillar or spindle, round which the turret revolves. The iron wall of the pilot house is pierced with sight holes. Within the pilot house, the steering wheel is placed, and the captain of the vessel can there direct the steersman, while the gunners are below the grated platform on which he stands, and therefore easily accessible to instructions. The ventilation of the ship is maintained by fans, which suck the air through high trunks or tubes, made shot-proof, and also inaccessible to rain or spray, the top being covered by a hood. The air, after having traversed the ship, finally enters the furnaces and escapes by the chimney, the bottom part of which is made shot-proof, and a grating of bars is also carried across it to prevent shells from being sent

through the chimney into the flues of the boiler. The bell mouth of the turret has a promenade or platform carried round its edge; and a narrow grated hurricane deck, supported on pillars, is carried from the after side of the turret for some distance towards the stern. From this deck the ship's boats are suspended.

Performance of Monitors as Cruisers at Sea.—Captain Fox, the assistant secretary of the American navy, reported as follows to his government on the performance of the Monitor vessel Miantonomah, on her voyage across the Atlantic, as illustrating the efficiency of such vessels as fighting cruisers. 'The facts with regard to the behaviour of this vessel in a moderate gale of wind and heavy sea, when a frigate would find it impossible to use her battery, are as follows: With head to the sea she takes over about 4 feet of solid water, which is broken as it sweeps along the deck, and after reaching the turret is too much spent to prevent the firing of the 15-inch guns directly ahead. With broadside to the sea, either when at rest or while moving, her lee guns can always be worked without difficulty—the water which passes along the deck from windward being divided by the turrets, and her extreme roll so moderate as not to press her lee guns near the water. Lying in the same position, her 15-inch guns can be fired directly astern without interference from water; and when stern to the sea, the water which comes on board is broken up in the same manner as when going head to it. . . . The extreme lurch, when lying broadside to the sea in a moderate gale, was 7° to windward and 4° to leeward, average 5½°, while the average roll at the same time of the Augusta, a remarkably steady ship, was 18°, and of the Ashuelot 25°, both vessels being steadied by sail. A vessel which attacks a Monitor in a seaway must approach very close to have any chance of hitting such a low hull, and even then the Monitor is half the time covered by 3 or 4 feet of water, protecting her and disturbing her opponent's fire. From these facts, not unknown to Monitor men, and the experience we derived from the use of such vessels during the war, we may safely conclude that the Monitor type of iron-clads is superior to the broadside, not only for fighting purposes at sea, but also for cruising. A properly constructed Monitor possessing all the requirements of a cruiser, ought to be constructed of iron and have but one turret, armed with not less than 20-inch guns, two independent propellers, and the usual proportion of sail.'

In regard to comfort and healthfulness, it appears, by a report presented by the secretary of the United States Navy to Congress, that the Monitors are the healthiest vessels in the American fleet, and they are also the most popular with the seamen. The cabins are lighted from the deck with bulls'-eyes, proper shutters being provided to cover these lights when the vessel goes into action, at which times the cabins are lighted by lamps alone.

On the subject generally, it may be added that the following opinions are entertained by some who advocate the adoption of Captain Coles' system. There is nothing in his design, it is urged, to preclude artificial ventilation; and it is affirmed that the narrow orifice between the upper deck and the turret is covered with a weighted massive leather flange, amply sufficient to keep out splinters; that under the heaviest fire at short range, under the most disadvantageous circumstances, the turret never has jammed, whereas those of the Monitors have done so; that they prefer hand-winches as motors, though there is nothing in the system to preclude a donkey engine for the purpose; that a worse pressure is exercised on the ship by a heavy turret on a spindle, than when diffused on its periphery; that the Monitor turret has to be lifted completely off its metal ring before it can be made to revolve, and that a trifling derangement would then upset the working of the spindle; and lastly, it is urged against the Monitors, that the whole height of the turret offers a perpendicular mark to the enemy, being entirely above the upper deck, while the Coles turret only exposes some four or five feet in which the guns are worked.

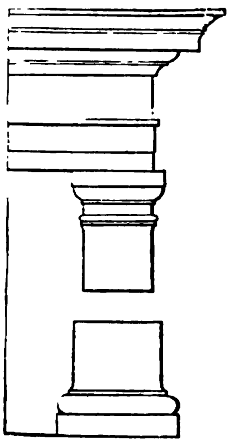
On the other hand, however, it is alleged, by those who think less favourably of Coles' system, that though there is nothing to hinder artificial ventilation in his more than in other vessels, yet that its adoption would only be a new appropriation of Ericsson's ideas, similar to that which took place when Coles discarded his own sloping shields in favour of the Monitor turret; that the weighted massive leather flange must present such enormous friction as to hinder rotation if sufficiently weighted to be splinter-proof; that if Monitor turrets have ever jammed (which is not admitted), the event has been exceptional, and that the Monitors, after having been each on the average twenty-five times in action during the course of the American civil war, remained practically unharmed at its close, whereas Coles' vessels have never been similarly tested; that the Monitor turrets may be rotated without lifting the spindle, though the lifting of the spindle is advisable, and that there is no risk of upsetting them when thus lifted, since they are lifted so little that the least springing of the spindle, such as would occur on the application of any side strain, causes the edge of the turret to rest on the deck ring; also, that Monitor turrets need be no higher than Coles' turrets, as both have only to keep the ports sufficiently clear of the deck to obviate injury to the deck from the cone of explosion.

Turrilepas (Lat. turris, *a tower*, and lepas; Gr. λεπάς, the word applied originally by Linnæus to the barnacles). A new genus of pedunculate Cirriped Crustacea, discovered by Mr. H. Woodward in the Wenlock Limestone of Dudley, and up to the present time the oldest known cirripede. It possesses intersecting rows of plates, symmetrically disposed like those of the chalk form of parasitic Cirriped *Loricula*.

Turtle (Lat. turtur). This word is used to signify a species of dove (*Columba turtur*), and also a genus of Chelonian reptiles (*Chelone*, Brongn.).

Tuscan Language. A name proposed in the sixteenth century to designate the language now known as the Italian, but which some desired to characterise as Florentine. (Hallam, *Literary History*, part i. ch. ix. sec. 31.) [ROMANCE LANGUAGES.]

Tuscan Order. In Architecture, one of the five orders, and the simplest of them all.



It is not found in any ancient example. Palladio has given two examples of this order, from one of which the profile here given is adopted, though some have preferred the profile composed by Vignola. The base consists of a simple torus with its fillet, accompanied by a plinth. Sir William Chambers assigns to the column, with its base and capital, a height equal to seven of its diameters. Vitruvius speaks of this order with little praise, but Palladio commends it for its great utility. It does not allow the introduction of ornament; and its columns are never fluted.

Tussac Grass. A name given to the *Dactylis cæspitosa* of the Falkland Isles.

Tutenag. An alloy of copper, zinc, and nickel, made in China; the term is also sometimes applied to a pale brass, and to bell-metal. [PAKFONG.]

Tutors. At Oxford and Cambridge, each college maintains a certain number of tutors, varying according to its size: at some, each undergraduate is placed under one of these tutors; at others, the work to be done is classified and divided between the tutors. They are, in general, fellows of the college, and are paid by fees. [UNIVERSITIES.]

Tutti (Ital.; Lat. totus, *the whole*). In Music, a notice to the performer that, from the place to which it is affixed, all the parts are to play together. This word is generally used to contradict the word SOLI or SOLO.

Tutty. An impure oxide of zinc collected from the chimneys of the smelting furnaces.

Twelfth Day. The festival of the Epiphany, or Manifestation of Christ to the Gentiles; being the twelfth day, exclusive, from Christmas. [EPIPHANY.] For the customs peculiar to this day in England, see Brand's *Popular Antiquities*.

Twelve Tables, Laws of the. In Roman History, the name given to the tables which were said to contain the legislation of the DECEMVIRI. This legislation is asserted to have been based on Greek models, but for this there is not the slightest historical evidence, while the story of the Tables is itself full of contradictions. According to Dionysius and Livy, the decemvirs in their first year of office framed a code inscribed on ten brazen tables (one for each decemvir), which received the sanction of the senate, and were fixed up in a conspicuous part of the forum. After this, according to Livy, the decemvirs who wished to resign were kept in office by the people, who thought that two tables were wanting to complete the code, and who, having come to hate the name of consuls scarcely less than that of kings, regarded the appeal from one decemvir to another as supplying the place of tribunitian interference. According to Dionysius, the decemvirs not only wished to retain irresponsible power in order to complete their code, but desired to prolong the suspension of the tribuneship. Of the character and contents of the two tables, said to have been added in their second year of office, Livy says nothing. According to Dionysius, they were added by Appius Claudius, and contained a prohibition of marriages between patricians and plebeians. Cicero mentions this prohibition as one of his reasons for drawing a broad distinction between the ten and the two later tables, which he stigmatises as unjust. But, according to Dionysius, and even according to Livy, the idea of the decemviral legislation was democratic, this character being involved (1) in the equalisation of the rights of plebeians and patricians, and (2) in the substitution of written laws for unwritten customs, a practice regarded by the Greeks as of democratic tendency.

The text of the twelve tables has been lost, as well as the description which Dionysius gave of their contents; but Sir G. C. Lewis maintains that, 'we know enough concerning them to authorise us in saying that they had not the character of a constitutional code, and that they contained nothing which placed the plebeians on a footing of political equality with the patricians. The political inequality between the two orders remained not less after the decemviral legislation, than it had been before. All the great constitutional changes, by which the plebeians achieved this equality, are mentioned as separate and successive measures, after the fall of the decemvirs. There is therefore nothing in the results of the decemviral legislation to explain the eagerness of the plebeian body to obtain it; the laws have not the character which we are told that they were intended to possess.' But our accounts assert that the ten tables were framed in accordance with the wishes of the plebeians, and as they appear to have contained nothing by which those wishes were carried into effect, 'the accounts of the purposes and circumstances of the legislation cannot be reconciled with its results,' and the conclusion is that 'the entire subject of the enactment of the decemviral code is in a state

of hopeless confusion.' (*Credibility of Early Roman History*, ch. xii. part iii. sec. 54.)

Twelve-hind Man. [THANE.]

Twelvemo. In Printing, the same as DUODECIMO.

Twenty-fours. In Printing, a sheet of paper which, when printed, folds into twenty-four leaves or forty-eight pages. The book is called a 24^{mo}.

Twilight (Ger. zwielicht). In Astronomy, the faint light which is perceived for some time after sunset and before sunrise.

The twilight is produced by the reflexion of light from the atmosphere. When the sun descends below the horizon, the rays of light no longer reach the earth directly; but as they pass through the atmospheric strata some of them are reflected towards the earth, and illuminate its surface. At first the light, falling on the lowest and densest strata, is reflected in great abundance; but as the sun descends to a greater distance below the horizon, the rays fall on strata at a greater height, and consequently less dense. A smaller number of them, therefore, suffer reflexion; and as this number is constantly diminishing, the strength of the twilight diminishes in the same proportion, till at length the solar rays fall on strata so rare as to be incapable of reflecting light, and the twilight accordingly disappears. In the morning the change from darkness to light takes place by the same gradations.

From this theory it is evident that twilight must begin and end when the sun's depression below the horizon attains a certain limit. The limit, however, cannot be fixed with any precision. It is usually estimated according to the time which elapses from sunset till the smallest stars which are seen by the naked eye become visible. But this mode of estimating the duration of twilight is uncertain and arbitrary; and it will be reckoned greater or less according to the goodness of sight of the observer, and the temperature and pressure of the atmosphere. Accordingly, the sun's depression at the beginning and end of twilight has been fixed at various limits by different observers: by Alhazen, at 19°; by Tycho, at 17°; by Rothman, at 24°; by Stevinus, at 18°; by Cassini, at 15°; and by others at different quantities; but the limit usually assigned is 18°.

Twilight of the Gods. [ODIN.]

Two-line Letters. In Printing, capitals which are equal to two bodies of any specific size of type. They begin with 2-line pearl (equal in depth to a longprimer), and increase regularly up to a 2-line great primer. They are used for lines in title-pages, the large letters at the beginning of advertisements in newspapers, &c.

Tycoon. The name by which the hereditary prime minister of Japan is commonly known to Europeans. This title, it seems, is applicable to the real emperor only, who is styled *mikado*, and who by Europeans is supposed to be only a spiritual sovereign, while the tycoon is the temporal ruler. The distinction is, apparently, erroneous, the relation of the so-called tycoon to the mikado being precisely that of the Frankish MAYORS OF THE PALACE to the Merovingian kings. Like the latter, the mikado is kept as much secluded as possible from the knowledge and observation of strangers and foreigners, while the tycoon, properly called *thoorgum*, wields the whole power of the state by holding in his possession the capital Yeddo, while for his authority he falls back on the emperor or mikado, for whom the reverence of the Japanese is so great that they will obey any usurper who holds his person and rules in his name.

Tylophora (Gr. τύλος, *a knot*, and φέρω, *to bear*). A considerable genus of *Asclepiadaceæ*, confined to the tropical and warm regions of the Old World; and consisting of twining mostly thin-leaved herbs or shrubs, bearing slender flower-stalks proceeding from between the leaves, and having umbels of small flowers disposed alternately along them. *T. asthmatica*, a twining shrubby species with slender branches, native of the Indian Peninsula, Ceylon, the Moluccas, &c., yields a strong white silky fibre resembling that of the Yercum (*Calotropis gigantea*). Its roots also possess valuable medicinal properties, acting in large doses as an emetic, in consequence of which they are substituted in India for ipecacuanha, and in smaller doses are used as a cathartic. They have been successfully employed in epidemic dysentery, and are said to have a good effect in humoral asthma. The Cingalese call the plant Binooga, and the natives of Madras, Koorinja.

Tympan. [PRINTING.]

Tympanitis or **Tympany** (Gr. τυμπανίτης). A distension of the abdomen, arising from a morbid collection of gas in the intestines. The disease is sometimes termed *drum belly*, and arises occasionally from air secreted into the abdominal cavity, at the fatal termination of abdominal inflammations and of fevers. In cattle, this disease is known to veterinary practitioners under the name of HOVEN.

Tympanum (Lat.; Gr. τύμπανον, *a drum*). The drum of the ear; the cavity behind the membrane of the tympanum, surrounded by the tympanic, mastoid, and petrous portion of the temporal bones, and terminating at the labyrinth; it contains the four small auditory bones, and the Eustachian tube opens into it.

TYMPANUM. In Architecture, the space in a pediment enclosed by the cornice of the inclined sides and the horizontal fillet of the corona.

TYMPANUM. In Botany, a membrane which stretches across the mouth of the spore-case of some urn-mosses.

Type (Gr. τύπος, literally, *a blow*, hence the mark left by a blow). In the Fine Arts, the model or pattern, in nature, of any object. Thus, in architecture, the types of columns are said to be trees, &c.

TYPE. In Printing, the letters, marks, and signs of all kinds (the small sizes cast in metal, the largest cut in wood) with which books, newspapers, broadsides, &c. are printed.

Roman and Italic types are the letters most commonly used in printing books in Europe and America, and these have undergone every change in form that fancy or taste could suggest: *fat-faced*, or those which print black; *skeleton*, or those with a fine uniform line; *antique*, or those with an almost uniform thickness, but strong and heavy; *clarendon*, a modification of antique; *expanded*, or letters widened horizontally; *Elzevir* and *compressed*, or tall, thin letters; *Baskerville*, a good, round, bold face; *Italic*, inclining to the left as well as to the right; *black*, and all its varieties of *church-text*, *German text*, *Gothic*, and *Elizabethan*; *old cut* and *old style*; *script*, &c.

The scale of sizes given below from Savage shows the variations in the depth of the types cast by the different founders.

Number of Lines of the different sized Types contained in One Foot.

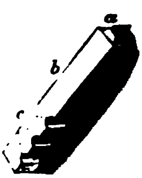
It will be seen that in Moxon's time, in 1683, there were only ten types with specific names, while we have now twenty-one.

The type itself is a thin metallic bar, an inch in length, like the following engraving, which represents the letter *m*; *a* is the *face*, *b* the *body*, and *c* the *nicks* or notches. Whatever size of type is used, each letter must be perfectly true in its angles, otherwise the form, or mass of types, could never be *locked up*.



The materials from which types and stereotype plates are cast are technically termed *metal*, and consist of certain proportions of lead, tin, and antimony, melted together. Until recently types were always cast in little moulds held in the hand, the melted metal being poured in from a small ladle; but now they are thrown off with great rapidity by machinery. The type-casting machine consists of a mould, constructed so as, by means of a crank, to open for the purpose of letting the type drop out, and then to shut up together again very closely and exactly; the opening and shutting being performed every time the crank is turned once round. Each time the crank revolves, it is brought up to the furnace-mouth (a small orifice not much larger than a pin-hole), and takes a supply of metal. This metal is driven by a force-pump in a reservoir, worked by the crank, into the mould, and the type is formed. The types are then rubbed smooth upon stones; *set up*, or arranged in rows, for inspection by the *dresser*, who carefully examines them, and rejects those which are bad, giving the perfect ones the finishing touch. The most complete process is, perhaps, that of Messrs. Johnson and Atkinson. A double line of grooves is placed side by side. At one end is a reservoir of molten metal, to which the mould is brought; a jet of metal is thrown into the mould, which then opens, and deposits the type on a travelling apparatus in the groove. As the groove fills, it is impelled along, and in its progress the shanks are taken off. At the end the position of the type is reversed by the machinery into the returning groove, in which it is rubbed, dressed, has the bottoms planed, and the nicks cut. On arriving at the exit end of the groove it is received into a type-founder's stick, which has to be removed as it is filled, and the type is then ready for packing. The great advantage of type machines consists in the increased facility of production. One machine and one man will produce in ten hours 30,000 brevier types (or 60 lbs.), while

by hand labour only 5,000 (or 10 lbs.) could be cast in the same time. Messrs. Miller and Richards, of Edinburgh and London, employ not less than eighty steam type-casting machines, equalling in production the labour of 480 men.

The beauty of type depends upon the delicacy with which the *matrix*, or mother type, is formed. This mould is a short thick bar of copper, with the form of the letter intended to be produced stamped in one side of it, thus:—

The letter in the matrix is stamped in by means of a punch, a small piece of steel,

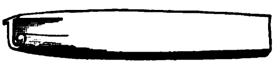
a letter cut upon one end, and the other end a flat head to receive the blow of a hammer.



The length of the body of a type is called its *height to paper*, and this is unfortunately not uniform, there being a *London* and a *Scotch* height, the former not so high as the latter.

A complete assortment of types is called a *fount*, which may be regulated to any extent. Every type-founder has a scale showing the proportional quantity of each letter required for a fount; and a peculiar scale is required for each language. For the English language, a type-founder's scale, or *bill*, for a fount of the weight of 800 lbs. is given above, from which it will be seen that in the English language the letter *e* is more frequently used than other letters, and *z* the least. In setting up indexes and similar matter, the capitals mentioned in the scale would be considerably deficient. This would also be the case with French and Italian works, where accented letters are used in great numbers.

In the last century, a fount of type weighing 500 lbs. was considered a good weight; but now,

so much has printing increased, it is not an uncommon thing in the principal houses in London to keep a fount of 20,000 or 30,000 lbs. in constant use. The following are the names of the types in English, Dutch, French, German, and Italian; but some of the German names vary in different parts of Germany.

1. Diamond, the smallest.
2. Pearl. (*Fr.* La Parisienne or Sédanoise; *Ger.* Perl; *Ital.* Occhio di Mosca.)
3. Ruby.
4. Nonpareil. (*Dutch*, Nonpareil; *Fr.* La Nonpareille; *Ger.* Nonpareille; *Ital.* Nompariglia.)
5. Emerald.
6. Minion. (*Fr.* La Mignonne; *Ger.* Colonell; *Ital.* Mignona.)
7. Brevier. (*Dutch*, Brevier; *Fr.* Le Petit Texte; *Ger.* Petit, or Jungfer; *Ital.* Piccolo Testo.)
8. Bourgeois. (*Dutch*, Bourgeois; *Fr.* La Gaillarde; *Ger.* Burgeois; *Ital.* Gagliarda.)
9. Long Primer. (*Dutch*, Garmond; *Fr.* Le Petit Romain; *Ger.* Corpus, or Garmond; *Ital.* Garamone.)
10. Small Pica. (*Dutch*, Dessendiaan; *Fr.* La Philosophie; *Ger.* Brevier, or Rheinländer; *Ital.* Filosofia.)
11. Pica. (*Dutch*, Mediaan; *Fr.* Le Cicéro; *Ger.* Cicero; *Ital.* Lettura.)
12. English. (*Dutch*, Augustyn; *Fr.* Le Saint Augustin; *Ger.* Mittel; *Ital.* Silvio.)
13. Great Primer. (*Dutch*, Text; *Fr.* Le Gros Romain; *Ger.* Tertia; *Ital.* Testo.)
14. Paragon. (*Dutch*, Paragon; *Fr.* Le Petit Parangon; *Ger.* Paragon; *Ital.* Paragone.)
15. Double Pica. (*Dutch*, Dubbelde Dessendiaan; *Fr.* Le Gros Parangon; *Ger.* Text, or Secunda; *Ital.* Due Linee Filosofia.)
16. Two Line Pica. (*Dutch*, Dubbelde Mediaan; *Fr.* Les Deux Points de Cicéro; *Ger.* Doppelcicero.)
17. Two Line English. (*Dutch*, Dubbelde Augustyn; *Fr.* Palestine; *Ger.* Doppelmittel; *Ital.* Canoncino.)
18. Two Line Great Primer. (*Dutch*, Kanon; *Fr.* Petit Canon; *Ger.* Kleine Canon; *Ital.* Grosso Testo.)
19. Two Line Double Pica. (*Dutch*, Groote Kanon; *Fr.* Trismegiste; *Ger.* Grobe Canon.)
20. Trafalgar.
21. Canon. (*Dutch*, Parys Romeyn; *Fr.* Le Gros Canon; *Ger.* Kleine Missal; *Ital.* Canone.)

Canon is the largest English size with a specific name; Pica then becomes the standard to distinguish them, and the next size to Canon is Four Line Pica, then Five Line Pica, and so on, to the largest size used in posting bills.

Subjoined is a specimen of the sizes of types up to Great Primer inclusive, the numbers corresponding to the numbers and names above.

1. To enable the reader to form an opinion of the comparative sizes of
2. types, and the proportions they bear to each other, there is given
3. in this paragraph a line of each size, from Diamond, the
4. smallest type in general use in England, up to Great
5. Primer, inclusive, numbered to correspond with
6. the preceding list, in order to distinguish
7. them by their names. There is a smaller
8. type than Diamond lately introduced,
9. but it is as yet little used. The
10. French have one so small that
11. it cannot be read by the
12. naked eye, even by
13. young persons.

In 1457 cast types were invented by Peter Schoeffer; in 1800, the lever, or American mould, was introduced; in 1823, Henri Didot's polymatype, still successfully used in France, was worked in London by Pouchée, but failed through the opposition of the associated type-founders; in 1853, Mr. Johnson patented his machine for casting type mechanically without variation of body; and in the year following, he perfected his process for making hard metal type by substituting tin for lead entirely or partially in the ordinary compounds.

TYPE. Properly, the figure stamped upon a coin: hence, a sign or symbol, especially those by which it is said that Christ was prefigured to the Jews, whether figures, as the Brazen Serpent, the Lamb of the Passover, the Sacrifice of Isaac; or persons, as Moses, David, Jonah, &c.

Type of Constans. [ECTHESIS; HENOTICON.]

Type Metal. The alloy of lead and antimony used in casting printer's types, the usual proportions being one part of antimony to three of lead, but a superior and harder kind of type is sometimes made by alloying two parts of lead with one of antimony and one of tin. Both these alloys take a sharp impression from the mould or matrix, owing to their expansion on solidification, and they are hard enough to stand the work of the press, without being brittle or liable to fracture.

Typhaceæ. An order of Endogens, consisting of reed-like herbs growing in marshes, ditches, or shallow water, and having long narrow parallel-veined leaves, and small flowers densely packed in cylindrical spikes or globular heads. In structure they come near to *Araceæ*. The flowers are monœcious, without any perianth, unless the small scales or tufts of hairs intermixed with the stamens and ovaries be regarded as such. The ovary tapers into a slender simple style, and ripens into a small nut with a single pendulous seed; the embryo is straight, lying in copious albumen. There are very few species, but some of them are dispersed over nearly all parts of the globe. The genus *Typha* is a good illustration.

These Typhas are tall herbaceous aquatics, distinguished by their flowers forming a continuous spike or spadix shaped like a constable's mace. The two British species, *T. latifolia* and *T. angustifolia*, often popularly but erroneously called Bulrush (which name properly belongs to the genus *Scirpus*), are common on the borders of ponds and lakes, where their singular large terminal spikes (called from their form Cat's-tail, or Reed-mace) present so picturesque an appearance, that they are often selected by artists to indicate the presence of water. *T. latifolia* grows to the height of five or six feet.

Typhaon (Gr.). In Greek Mythology, this name is the same as that of Typhöeus, or Typhon; but in the Hesiodic *Theogony*, Typhaon and Typhöeus are distinct personages, the former being a son of Typhaon. In one tradition, the latter is described as a son of Gaia and Tartarus;

in another as a son of Hera, who produced him by her own unaided power, as Athena sprang armed from the forehead of Zeus. [TRITOGENEIA.] In another version it is Hephæstus, and not Typhaon, who stands in this relation to Hera.

Typhōeus is mentioned in the *Iliad* (ii. 782) as imprisoned in the country of the Arimi. By later poets he is connected with the Egyptian mythology, which, according to Sir G. Wilkinson, had two deities, 'one who was the brother of Netpe, and opposed to his brother Osiris, as the bad to the good principle; the other, bearing the name of Typho, and answering to that part of his character which represents him as the opponent of Horus.' (*Ancient Egyptians*, vol. iv. p. 417 &c.)

Typhon belongs to the same class of beings with ECHIDNA, FAFNIR, PYTHON, the SPHINX, &c.

Typhoon. The name given to a violent tornado or hurricane in the Chinese seas. [STORMS.]

Typhus (Gr. τῦφος, from τύφω, *to smoke*). This term (implying to burn with a concealed and smothered flame) is applied to certain continued fevers, attended by great debility. It is contagious or infectious, and often epidemic, and is most prone to attack debilitated persons, especially where aided by want of cleanliness, good food, and fresh air; so that it often spreads in hospitals, gaols, camps, and other situations where such causes assist its progress. This form of fever is liable to several modifications, commonly termed *low fever*, *putrid fever*, *nervous fever*, *gaol fever*, &c. Its attack is generally characterised by inordinate muscular and nervous debility, and by great depression of spirits, weariness, flying pains, sighing, and a frequent, small, and sometimes fluttering pulse; the tongue is foul and brown, and the taste impaired, and not unfrequently nausea and bilious vomiting prevail, constituting that variety of typhus which has been called *bilious fever*. About the fourth or fifth day, an eruption appears upon the abdomen, having a deep colour, approaching sometimes to extreme lividity. These spots do not disappear on pressure, like those of typhoid fever. As the disease advances, the debility increases; the mouth becomes very foul, and the breath fetid; the urine deposits a brown sediment, and, together with the motions, is fetid, and rapidly putrefies. All these symptoms increase in intensity; the speech becomes inarticulate, muttering, and delirious; there is a tendency to bleeding from the nose, mouth, and bowels; petechiæ, or livid spots, appear upon the surface; the pulse sinks and intermits; the mind wanders; hiccup comes on; the hands and feet become cold; and, under these horrible symptoms, the patient dies. Such is an outline of the progress of a typhus fever to a fatal termination. In this climate it may endure for from two to three weeks; but in hot countries the symptoms follow each other more rapidly and violently, and it is not of more than eight or ten days' duration. When it does not terminate fatally, the symptoms begin to assume a more favourable aspect about the fourteenth day; the pulse improves, the patient gets some tranquil sleep, perhaps perspires; the urine deposits a red sediment; bilious stools are passed; he becomes more tranquil in mind and body, and his symptoms gradually disappear till health is restored; but it is a disease the event of which must be anticipated with the utmost caution, for attacks apparently mild sometimes terminate fatally, and in other cases the constitution has rallied under the most alarming and malignant features. At the very commencement an emetic sometimes acts advantageously. It is possible that some particular symptom, indicative of local congestion, may call for treatment. Serpentaria, Peruvian bark, cascarilla, and colombo are the tonics which have been most relied on, but in the present day little else is used than mild nourishing fluid diet, and alcoholic stimulus as the case progresses, or sometimes at the onset. In all cases, the utmost attention must be paid to extreme cleanliness, frequent change of linen, ventilation, and the due use of disinfectants.

Typography. The art of Printing. [PRINTING.]

Tyr. In Teutonic Mythology, the sun-god, answering to the Vedic Dyu. Like SAVITAR, he is represented as one-handed; but the German story is that Tyr placed his hand as a pledge in the mouth of the wolf, and that the wolf bit it off. With the two legends which relate the mutilation of Tyr and Savitar may be compared the Norse and African tales, which profess to account for the tailless condition of the bear and the hyæna. (Dasent, *Popular Tales from the Norse*, li.)

In the Edda, Odin is the supreme god, but there is evidence that before his pre-eminence was established, Tyr was worshipped as the principal deity of the Germans, being etymologically the same as the Greek ZEUS. The name survives in the Anglo-Saxon Tiwesdæg, *Tuesday*; in the names of places, as Tewesley, Tewing; and of flowers, as in the old Norse Týsfiola, Týsvidr. According to Tacitus, the Germans spoke of themselves as sprung from Tuisco (Zeus), and his son Mannus. [MINOS.] This Mannus is the Sanscrit Manu, from the root *man*, to measure, to think, from which is derived the Old High German *mennisc*, and the modern *mensch*, *mennisc* meaning a son of man. 'As soon as *mennisc* and *manushya* became in common parlance the recognised words for man, language itself supplied the myth that Manus was the ancestor of the Manushyas. . . . Hence *Mannu* was called the son of Tuisco, and this Tuisco, as we know, was originally the Aryan god of light.' Tacitus mentions the three tribes, Ingævones, Iscævones, and Herminones, as sprung from the three sons of Mannus. Of these, the first derive their name from Yng, Yngo, or Ynguio, whom the Edda has mentioned as living first with the eastern Danes, probably as Augê is to be found in Mysia, and Phœbus in the Lykian (Lycian) land. The second son, Isco, has been identified by Grimm with *Askr*, whose name means *ash-tree*, and thus embodies

probably the same conception which led the Greeks to speak of men as sprung (ἐκ μελιᾶν) from ash-trees. 'Alcuin still uses the expression *son of the ash-tree* as synonymous with man. The third son of Mannus, Irmino, has a name decidedly German. Irmin was an old Saxon god, from whom probably both Arminius and the Herminones derived their name.' (Max Müller, *Lectures on Language*, second series, x.)

Tyrannicide. [LIBERTY; REGICIDE.]

Tyrant (Gr. τύραννος). In the original sense of the word, a citizen who acquired sovereignty by subverting the constitution of a free state, whether by violence or stratagem, was called, in the language of Greek political writers, a tyrant, as distinguished from the *basileus*, or rightful hereditary king, whether despotic or constitutional. [LIBERTY; REGICIDE.]

Tyrite. A hydrous mineral allied to Fergusonite, occurring abundantly (sometimes in crystals more than two inches long) in a large felspar quarry at Helle near Arendal in Norway. It chiefly consists of columbic acid, yttria, alumina, the protoxides of cerium, uranium, lanthanium, and iron, lime, zirconia, and glucina.

Tyrolite. A hydrated arseniate of copper with carbonate of lime, composed of 25·4 per cent. of arsenic acid, 43·8 oxide of copper, 19·8 water, 11·0 carbonate of lime. It occurs at Falkenstein and other parts of the Tyrol (whence the name), usually in small reniform aggregations and diverging fibrous groups of a pale green colour, and with a pearly lustre. It is very sectile, and in thin laminæ flexible. [KUPAPHRITE.]

Tyrosin (Gr. τυρός, *cheese*). A crystalline substance originally obtained from cochineal. It is artificially produced by the fusion of caseine, fibrine, or albumen with potassa, or by boiling the same substances with dilute acids, and is sometimes the result of their putrefaction. The formula assigned to it is $C_{18}H_{11}NO_6$.

Tythe. [TYTHING.]

Tything. A tything was a subdivision, i.e. a tenth part, as its name indicates, of the hundred, with which it was probably coeval in institution, as it was certainly identical in object, so far at least as regards the prevention of offences by the condition of liability for the production of offenders, or in default thereof reparation of the mischief, in the case of offences committed within the district. For this purpose, all free persons above the age of twelve years were required by the Saxon law to belong to some tything. No jurisdiction appears to have belonged to the tything; and the office of tythingman, or constable, seems always to have been confined, as it is now, to the preservation of the peace, and the apprehension of offenders. The limits of a tything were in most cases coextensive with those of a parish, with which it is now commonly, for practical purposes, identical.

U

U. This letter was long identified with V, and both were used indiscriminately; but at the beginning of the sixteenth century their peculiarities came to be marked, and *u* has since been used as a vowel and *v* as a consonant.

Ubiquists or **Ubiquitarians** (Lat. ubique, *everywhere*). In Ecclesiastical History, a school of Lutheran divines: so called from their tenet that the body of Christ was present in the Eucharist in virtue of His divine omnipresence. Luther is said to have maintained this position, as a mode of reconciling the doctrine of transubstantiation with reason, for two years. Brentius, one of his disciples, passes for its principal supporter. Melanchthon opposed it; but it seems to have obtained great credit among the Lutherans of the sixteenth and seventeenth centuries.

Uckewallists. In Ecclesiastical History, a sect of rigid Anabaptists; so called from one Uke Wallis, a native of Friesland. They appear to subsist still, independent of other Anabaptists and Mennonites, in Friesland and Gröningen. (Mosheim, vol. v.)

Udal or **Udaller** (Dan. odel). A synonym of the Gothic and Frankish *alod*, a proprietor holding his lands under no feudal superior.

The settlers in France under Clovis parcelled out such lands as they appropriated into portions called alods, each allottee holding his own plot without any obligation to a feudal law, and being liable only to the general duty of defence—a duty which was known in later legal history by the name of TRINODA NECESSITAS. But the ancient population, now become Romanised, appear to have held the possessions relinquished to them by their conquerors on a lower and more precarious tenure. In course of time, however, the kings, whose powers increased with the settlement of the country, granted their followers and dependants, under the condition of attendance and military services, life estates, called *benefices*, or in the Frankish tongue *feuds*. Gradually and by insensible steps, as the allodialists became impoverished and insulated, they were forced to *commend* themselves to some lord, and the feudal system of homage, allegiance, and service, became general. This change was made more rapidly, as society was rendered more insecure by the danger of external aggression.

Among the Scandinavian races, the feudal system, in the absence of these contingencies, never took deep root, and consequently the old tenure survived, under the name *udal*, the owner

of the land being a *udaller*. This kind of occupation, which still characterises Norway, prevailed formerly in the Isle of Man, and is still found in the Orkneys and Shetland islands. The latter term, in something like the sense of an esquire or gentleman of estate, will be familiar to the readers of Scott's *Pirate*. On failure of heirs, such lands reverted in common to all owners on a similar title. Among Celtic races the custom of TANISTRY and GAVELKIND prevailed. It was probably in consequence of the reversionary interest of the sept or clan, that udal lands, even when sold, could always be redeemed within a fixed period by the seller. The following are illustrations of the tenure.

Prof. Keyser (*Norsk Church History*) says: 'The feudal system in its South German shape was unknown in Norway. In its stead the udal system prevailed, by which the land was the free possession of the udaller, over which the state or king had no superior right, and which it therefore could not tax. On the other hand, every Norwegian was bound to support the state by his *personal* service. In Norway, all services to the state were of a personal character, and did not depend on land or other property.'

See also the *Saga* of Olaf Tryggvason, 16. (*Flateybok*.) 'Hacon Athelstan was in England when he heard of the death of his father Harald the Fairhaired.' He started at once for Trondhjem, and at the Thing 'stood up and spoke as follows. He commenced by asking the bonders (peasants) to call him king and help him to hold the kingdom; in return for which he offered to make all the bonders odalbornna (udalborn), and give them their udal possessions (odul sin) on which they dwelt.'

'Again in the same saga (183), when Harald imposed a tribute on the Orkneys, earl Einar offered to pay the whole of it himself, if the peasants would give up their udal rights.'

Uigite. A hydrated silicate of alumina, lime, and soda, found in the amygdaloid of Uig in Skye.

Ukase. An ordinance of the emperor of Russia having the force of law in his dominions.

Ulcer (Lat. ulcus, Gr. ἕλκος, *a wound*). A solution of continuity in any of the soft parts of the body, attended by a purulent or other discharge. The several kinds of ulcers are divided by surgeons into *local* and *constitutional*, but these often run into each other. They have been termed *simple* and *specific* sores or ulcers: the former resulting from accidental injuries, the latter from specific poisons or particular habits of body. (Cooper's *Surgical Dictionary*.)

Ule-tree. The name of a tree from which caoutchouc is obtained. It is supposed to be the *Castilloa elastica*.

Ulema (Turk. *learned men*). The college or corporation composed of the three classes of the Turkish hierarchy: the *imans*, or ministers of religion; the *muftis*, or doctors of law; the *cadis*, or administrators of justice. This organisation, according to D'Ohsson (*Tableau de l'Empire Ottoman*), was first framed by the caliphs, and adopted, along with the other principles of their government, by the Ottoman sultans. Candidates for admission in the Ulema are educated at the different colleges (medressés) of the empire. The *Sheikh ul Islam*, or mufti of Constantinople, is the president of the whole body. (*Ed. Rev.* vol. l.)

Ulex (Lat.). A genus of prickly shrubs of the order *Leguminosæ*, distinguished by their twoparted calyx bearing two minute bracts at the base, and their turgid few-seeded legume. *U. europæus*, the Common Furze, Whin, or Gorse, is one of the few British social plants sufficiently important to give a name to the localities on which it fixes, a *Furze-brake* being a characteristic feature of English landscape. Harsh and rugged though Furze be in appearance, it has by no means a wide geographical range. Even in North Britain it dwindles in size, and in the more exposed regions is hardly known. In Russia and Sweden it occurs only as a greenhouse plant, and even in the south of England an unseasonably severe frost nips the flowers, or sometimes destroys all the exposed part of the plant. When regularly cut down every year, the annual shoots of the Furze, mowed as wanted, and bruised to deaden the prickles, supply a green food throughout the winter, which all animals, and especially horses, are particularly fond of. When cultivated, the seeds sown are either collected from the wild plants, or from a variety which, by successive cultivation, has become rather more succulent and productive. The double-flowered Furze of gardens is a variety of this species, as is also the Irish Furze, distinguished by the softness of its upright branches. *U. nana*, the Dwarf or French Furze, a much smaller plant, with flowers of a deeper yellow, blooms in the greatest profusion at the season when heath is in blossom, with which it harmonises beautifully in colouring.

Ulexite. A name given to native borate of lime (Hayesine), after Ulex, by whom it was analysed.

Ullage. In Gauging, this word is used to denote that quantity which a cask wants of being full.

Ullmannite. A sulphide of nickel and antimony; the latter often partly replaced by arsenic. It generally occurs massive, with a granular structure; or disseminated, and is of a grey colour inclining to tin-white or steel-grey; opaque with a metallic lustre. It is chiefly found in the copper mines of Frensberg, Eisern, &c. in the duchy of Nassau; in Siegen, Prussia; and at Harzgerode and Lobenstein in Central Germany. Named after Ullman, by whom it was analysed.

Ullucus. [MELLOCA.]

Ulmaceæ (Ulmus, the principal genus). A natural order of woody plants, usually timbertrees, inhabiting temperate climates. They are apetalous Exogens, nearly allied to the Urticaceous order, from which they principally

differ in having a two-celled fruit. The various kinds of Elm-trees are the best known species; but the thin papery fruit of these plants is merely a character of the genus *Ulmus*, and by no means characteristic of the order.

Ulmin (Lat. ulmus, *the elm-tree*). A dark brown substance which exudes from the bark of the elm and several other trees, and which appears to be contained in most barks. The brown matter found in decayed leaves and wood, and in soils abounding in decomposed organic substances, resembles ulmin. [HUMIC ACID.]

Ulmus (Lat. *an elm*). A genus of *Ulmaceæ*, consisting of hardy deciduous trees, some of which yield the valuable timber called *Elm wood*.

The Common Elm, *U. campestris*, is the most generally diffused species, though said to have been introduced into Britain by the Crusaders. It is a lofty upright-growing tree, composed of many tiers of spreading branches, which often hang in graceful festoons at the extremities. The Wych Elm, *U. montana*, is distinguished by its numerous spreading branches, which frequently droop so as to conceal the main trunk. The Elm was held in high estimation by the ancients, partly for the sake of its leaves, which were dried and employed as fodder, and partly for the use to which the tree itself was applied, viz. as a prop for vines. The former custom still obtains in some parts of the Continent; but the Elm is now principally valued for its timber, which is fine-grained, tough, possessing great lateral adhesion, and remarkable for its durability under water. Hence it is employed in naval architecture. It was formerly much used in making water-pipes. The Elm, growing in good soil, arrives at perfection in 150 years, but will live for 500 or 600 years. The Common and Cornish Elms are considered to afford the best timber.

The *Ulmus montana* is often called the Wych Elm and Witch Hazel, probably from the similarity of its leaves to those of the hazel-nut; and hence, like it, its twigs were formerly employed for riding-switches to insure good luck on the journey. Forked branches of Wych Elm, as of hazel, were used as divining rods. They were more usefully employed for making long bows, the archer esteeming them next to those of the yew for that purpose.

Ulna (Lat.; Gr. ὠλένη). The larger of the two bones of the forearm. It forms the joint of the elbow, and is articulated by a species of hinge-joint to the humerus, and to the radius; and below to the radius and to the bones of the wrist.

Ulnage or **Ulnager** (Lat. ulna, *an ell*). Edward I. and his grandson sought to naturalise the industry of the Flemish weavers in England, and settled a considerable number of these artificers in the eastern counties, which, in the fourteenth century, became the richest and most prosperous parts of England. But they did not prohibit the importation of foreign cloth, though they watched with considerable jealousy the exportation of British wool.

Partly, however, in order to prevent frauds on the customs, much more in order to secure the buyer of foreign stuffs, officials were appointed in each considerable port, who should measure and certify the length and quality of the piece (pannus) of 24 yards or ells; for in early times it seems that these words were synonymous. These officers were called *alnagers* or *ulnagers*, and the accounts rendered by them to the exchequer are still preserved in great fulness and continuity in the Public Record Office.

It should be remembered that the police of the middle ages, imperfect as it might have been, was employed in the general interests of society, and consequently that the supervision exercised over dealers was continual and rigorous. In short, the maxim of law, *caveat emptor*, was interpreted in bygone times in a somewhat different form from that which modern usage assigns to it. In our own day, it is hardly possible for the general public, in the exercise of individual discretion, to guard against the ingenuity of fraudulent traders; but in those times, the police was incessant and effective, and the buyer who was defrauded, was as little an object of compassion, as the man would be who thinks proper to traffic with a real or pretended smuggler, and finds himself cheated.

Ultimate Analysis. This term is applied in Chemistry to the resolution of substances into their absolute elements, and is opposed to *proximate analysis*, by which they are merely resolved into secondary compounds. The ultimate analysis of crystallised blue vitriol, for instance, teaches us that its true elements are sulphur, copper, oxygen, and hydrogen; its proximate elements are sulphuric acid, oxide of copper, and water; the ultimate elements of sulphuric acid are sulphur and oxygen; of oxide of copper, copper and oxygen; and of water, hydrogen and oxygen. The terms *ultimate analysis* and *ultimate elements* are, however, most generally used in reference to organic products. Gum resin, starch, and sugar, are often found associated in a vegetable, and are called *proximate* principles, and they are separated by proximate analysis; but all these are resolvable by ultimate analysis into carbon, hydrogen, and oxygen. These three elementary substances, therefore, are their *ultimate* components. The accurate determination of the relative proportions of the proximate constituents of the various organic products is often a difficult chemical problem.

So, again, various animal products, such as albumen, fibrin, gelatin, casein, &c., which are separable as distinct proximate substances, are found, in reference to ultimate composition, to consist of carbon, hydrogen, oxygen, and nitrogen, to which sulphur and phosphorus, together with some mineral substances, are superadded. [ANALYSIS, in Chemistry.]

Ultimate Ratio. The ratio of evanescent quantities. [PRIME AND ULTIMATE RATIO.]

Ultimatum (Lat. ultimus, *last*). In Diplomacy, the final conditions offered by a government for the settlement of its dispute with another.

Ultra (Lat. *beyond*). In Modern Politics, those who carry to their farthest point the opinions of the party to which they belong are so termed. The name was applied in 1793 to the more violent revolutionists; it has since been bestowed on the extreme section of all parties in turn.

Ultra-elliptic Functions. [ELLIPTIC FUNCTIONS.]

Ultramarine (Lat. ultra, and mare, *the sea*). The blue pigment obtained from the mineral *lazulite* or *lapis lazuli*. The mineral is ground to a fine powder and levigated. *Artificial ultramarine* is prepared by heating to redness a mixture of kaolin, sulphur, and carbonate of soda. Other processes have been employed, but this yields the best results of those that have been published, although there is little doubt that the manufacturers make use of improvements upon published methods. The nature of the blue colouring matter of ultramarine has given rise to much discussion: some have thought that it is due to a peculiar kind of sulphide of sodium; but it has been found that the presence of iron is indispensable for the formation of the colour. That sulphur is one of the necessary constituents, is proved by the fact that the colour is destroyed by the action of acids, sulphuretted hydrogen being simultaneously liberated. A peculiar transient blue colour is produced on mixing sulphuretted hydrogen with perchloride of iron; this seems to indicate that both iron and sulphur are involved in the formation of ultramarine. The tint of the artificial product is superior to that of the natural, whilst the cost of its manufacture is so low as to render it one of the cheapest pigments known.

Ultramontane (Lat. ultra, and mons, montis, *a mountain*). In Ecclesiastical language, those who maintain the most advanced theory of papal supremacy are so called, as distinguished from those who hold that the authority of a general council is paramount to that of the pope. The name is derived from the circumstance that the theologians of Italy, the country beyond the Alps, were considered more favourable to high papal doctrine than the Cismontane doctors of France and Germany. Although among the modern clergy of France the respective names of Frayssinous, Affre, Boyer, and Guillon have been added to the catalogue of the defenders of Gallican liberties, yet the *ultramontane* spirit is generally supposed to be far the most influential in the ranks of the clergy of the present day. [CONCORDAT.]

As to ultramontane jurists, see Savigny, *Hist. of Roman Law*, vol. vi.

Ulva (Lat.). A genus of *Algæ*, typical of the *Ulvaceæ*, and distinguished from *Porphyra* principally by its green colour. The most familiar species is *U. latissima*, which, from its being frequently attached to oysters, is called *Oyster Green*. This and *U. Lactuca* are sometimes eaten like true Laver, under the name of *Green Laver*. It is also used occasionally in Scotland as a sort of water-dressing bound round the temples, by way of remedy in cases of headache.

Ulysses. The Latin name of the hero who is called ODYSSEUS in the Homeric poems. This name, in the opinion of some mythologists, represents the Sanscrit Urukshaya, and the Greek εὐρυκρείων, *wide-ruling*.

Umbel. In Botany, a form of inflorescence in which all the pedicels proceed from a single point. If there is no subdivision, the umbel is called *simple*; but if the pedicels produce other umbels, as in Parsley, the umbel is *compound*.

Umbelliferæ (Lat. umbella, dim. of umbra, *a shade*). A natural order of epigynous Exogens, the species of which abound in all cool or temperate climates, and even occur in hot ones, though much more rarely. They are known in general by their flowers being disposed in an umbel. They have an herbaceous stem; leaves usually much divided, often inflated when they join the stem; and they have universally a dry fruit, which always separates into two dry one-seeded carpels or *mericarps*, resembling seeds, which indeed they are popularly but erroneously called. The real seed is inside, closely adhering to the outer pericarp: it has a minute embryo in the base of the horny albumen. The mericarps are furnished with a definite number of raised longitudinal ribs, and underneath the intervening channels are frequently placed elongated receptacles for essential oil, called *vittæ*, remarkably constant in each species in their number and position. It is chiefly from the arrangement of these ribs and vittæ, and from the shape of the enclosed albumen, that modern botanists have derived the characters by which the numerous genera of *Umbelliferæ* are distinguished.

Some of the species are poisonous, as Hemlock and Water Dropwort; others are esculents, as Celery, Carrot, and Parsnip; many yield aromatic fruits, as Caraway, Coriander, and Anise. A few of them secrete a fetid gum resin, of which Assafœtida, Ammoniacum, and Galbanum are examples. The species are very numerous, nor is it easy to recognise them with accuracy; and, unfortunately, no general rule has yet been discovered for distinguishing the poisonous from the harmless kinds.

Umber. Two distinct substances are used as pigments under this name. One is a variety of Peat or Brown Coal, large beds of which are worked near Cologne, and which is said to be largely used in the adulteration of snuff; the other, called *Turkish Umber*, is a variety of ochreous Iron-ore (Limonite) composed, according to the analysis of Klaproth, of 48 per cent. of peroxide of iron, 20 peroxide of manganese, 13 silica, 5 alumina, and 15 water. The term

Umber is said to be derived from Ombria or Spoleto, in Italy, where it was first obtained. It is also found near Castletown in the Isle of Man, and fine pigments are also made from the Umber which is procured in the iron mines in the Forest of Dean in Gloucestershire.

Umbilic (Lat. umbilicus). The umbilic of a surface is a point at which the normal sections have all the same radius of curvature. The curvature of the surface at such a point is said to be *spherical*. A surface of the n^{th} order has in general a definite number of umbilics, the methods for finding which are given in most text-books. A curve on the surface, every point of which is an umbilic, is called a *line of spherical curvature*. [CURVATURE.] An ellipsoid has four umbilics, each of which is in the plane of the greatest and least axes at a distance from the centre equal to the mean semi-axis. [CONFOCAL AND CONCYCLIC QUADRICS; CURVATURE, LINE OF.]

Umbilical Cord. In Anatomy, the cord-like prolongation of the teguments of the abdomen, including the vessels which pass from the fœtus to the placenta in placental mammals: or to the allantois and vitellicle in implacental mammals, birds, and reptiles; or to the vitellicle alone in plagiostomous fishes. In other fishes, in batrachians, and in most invertebrates, the vitellicle is sessile, and there is consequently no umbilical cord.

UMBILICAL CORD. In Botany, an elongation of the placenta in the form of a little thread, by which the seeds are sometimes attached, as in the hazel pea.

Umbilical Focal Conic of a Quadric Surface. The locus of point-spheres (umbilical foci), each of which has double contact with the quadric of such a nature that the planes of contact (and intersection) are real. These planes are always parallel to the circular sections of the quadric, and the umbilics of the quadric are clearly points in the locus; hence its name. [FOCUS.]

Umbilical Vesicle. The name given to the proportionately small vitellicle, or yolk bag, in man and most mammalia.

Umbilicate (Lat. umbilicus, *a navel*). In Zoology, when a pit, tubercle, or granule has a depression in its centre.

Umbilicus (Lat.; Gr. ὀμφαλός). This word signifies properly the navel: hence it was metaphorically applied to the two ends of the roller on which the manuscripts of the ancients were rolled, and which were usually adorned with ornamental knobs, while the ends of the parchments were filed with pumice-stone, in order that the folds might lie smooth and neat.

UMBILICUS. In Botany, the scar by which a seed is attached to the placenta, frequently of a different colour from the rest of the seed, and not uncommonly very dark-coloured. It is more commonly called *hilum*.

UMBILICUS. In Conchology, the aperture or depression in the centre, round which the shell is convoluted.

UMBILICUS. In Geometry, this term is used by the older geometers synonymously with focus.

Umbo (Lat.). A protuberance or boss. In Conchology, the point of a bivalve shell immediately above the hinge.

Umbonate (Lat. umbo, *a boss*). In Botany, this term is applied to parts which are round, with a projection in the centre, like the boss or *umbo* of an ancient shield; as the pileus of many species of *Agaricus*.

Umbra (Lat. *a shadow*). In Astronomy, this term is applied to the dark cone projected from a planet or satellite on the side opposite to the sun. [ECLIPSE.]

Umbraculum (Lat. from umbra). In Botany, a term applied to those convex bodies which in *Marchantia* terminate the seta, and bear the reproductive bodies on the under side.

Umbræ (Lat. *shades*). In Roman domestic life, a name given to uninvited guests brought by one who was invited.

Umbral Notation. An invention of Prof. Sylvester's by which quantities are represented by combinations of letters, or *umbræ*, which, taken separately, have no meaning. For DETERMINANTS, the notation is very convenient and frequently employed.

Umbrella (Lat. umbraculum, from umbra, *a shade*). In Asiatic countries, the umbrella has from time immemorial been regarded as the special ensign of royalty. As such it is used as a termination to the Buddhist topes, and the Hindu pagodas, which are all of the conical form. [LINGA; ROUND TOWERS; TEMPLE.] The umbrella so used is called a *tee*. Originally they seem in all cases to have been of wood. An example still exists in the cave of Karli, which Mr. Fergusson (*Handbook of Architecture*) thinks may possibly be the very umbrella first set up 1800 years ago. Sometimes three umbrellas were placed one over the other; and when, following the ordinary course of developement, they came to be copied in stone, a more complete architectural character was given to them, until at last they assumed something of a spire-like form. In the *tee* or tope-finial, Mr. Fergusson sees the model of all Chinese buildings; but, on the other hand, it is urged that a mere piece of detail, insignificant in size, could scarcely have been taken as the type of whole buildings and repeated with astonishing perseverance and monotony, as the domestic designs of the Chinese follow manifestly the same model with the *taas*, or pagodas, while if we regard the tent of the nomad as the original type of both, we at once have the clue to the baseless post without capital or entablature, to the projecting concave roofs and the curved spikes which fringe it, the pagoda being simply the repetition of one tent on another until it reaches the height required. (*Edinburgh Review*, January 1857, p. 124.)

Umpire (this word is thought by some to be derived from the Fr. impair, *uneven in number*, an umpire being a third party to whom a dispute is referred; while by others it

is referred to the Lat. imperium, *a command*). An umpire is properly a person whom two referees, each chosen by his client, being unable to agree, jointly choose to determine between them.

Un. In English compound words, this is a particle denoting separation or negation. It corresponds to the Greek ἀν, as in ἀνώδυνος, *anodyne*, i.e. *without pain*, or *allaying pain*. In Latin, it answers to *in*, as in *inconstans*, inconstant.

Unarmed. In Botany, this term is applied to those parts which have no spines, prickles, or other sharp hard projections. It sometimes means pointless.

Unbend. In Sea language, to take the cable from the anchor, a sail from its yard, &c.; to untie one rope from another.

Uncaria (Lat. uncus, Gr. ὄγκος, *a curve*, hence *a hook*). This name was formerly given to a group of Cinchonaceous climbing plants with hooked spines, belonging to the *Cinchonaceæ*, one of which affords the astringent masticatory or tanning material called Gambir or Terra Japonica. It is now transferred to a genus of *Pedaliaceæ*, of which *U. procumbens*, the only species, is commonly known as the Grapple-plant at the Cape of Good Hope and in other parts of South Africa, on account of its very curious fruits being furnished on all sides with strong-branched very sharp hooks, by means of which they lay hold of the clothes of travellers or the skin of animals with singular tenacity. Dr. Livingstone says that when these fruits happen to lay hold of the mouth of an ox, the animal stands and roars from pain and helplessness.

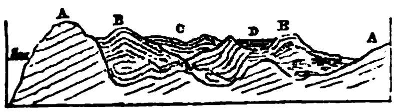
Unciæ (Lat.). The name given by the old writers on Algebra to the coefficients of the letters in the expansion of any power of a binomial. Thus, the expansion of $(a+b)^4$ gives $a^4+4\,a^3\,b+6\,a^2\,b^2+4\,a\,b^3+b^4$, in which the numbers 1, 4, 6, 4, 1, are the *unciæ*, or coefficients.

Unciales Literæ (Lat.). Uncial letters or writing. In Diplomatics, a species of character compounded between the capital and the minuscule or small characters; some of the letters resembling the former, others the latter. It is supposed to have been employed in Latin MSS. as early as the third or fourth century, but was seldom used after the tenth.

Unciform Bone (Lat. uncus, *a hook*). The last bone of the second row of the wrist bones; so called from its hook-like process in man, which projects towards the palm of the hand, and gives origin to the great ligament which binds down the tendons of the wrist.

Unconformable. In Geology, rocks are said to repose unconformably on one another when the lower rock has been removed from its original horizontal position, or has been denuded and its surface altered, before the overlying bed was deposited upon it. This condition is very common. It is illustrated in the accompanying diagram, where A A represents underlying rocks elevated at an angle of thirty degrees, and greatly denuded. The rocks B repose unconformably on A, and C again with equal want of conformability on A and B.

There may be absence of continued and unbroken succession even when there is no want



of conformability, while there may be apparent unconformability where the beds were really deposited in succession. This may arise in the first case from the fact that there had been no denudation in the exact spot where the beds are now laid bare, so that, although there has been great change and a long interval, there is orderly succession. The other case occurs when, owing to some local cause, or to the prevalence of different marine currents, parts of a deposit are swept away while other parts are being covered. In this case, although no perceptible or important interval has elapsed, and the rocks are strictly contemporaneous, they cease to be conformable in the strict sense of the word.

Unction, Extreme. [EXTREME UNCTION.]

Undecagon. [HENDECAGON.]

Underrun. In Sea language, to pass a boat or ship under a cable or rope, raising the latter above the surface for the purpose.

Undershrub. In Botany, the designation of a woody plant of small size, the ends of whose branches perish every year.

Understanding. A name given to that faculty by which man derives ideas from sensations. The impressions received from the outward world by means of the senses are regarded as the basis of all knowledge, and a creature destitute of perception would be incapable of learning or understanding. According to Aristotle, the one sense which is an indispensable condition for the acquisition of knowledge is that of touch. To the ideas formed immediately from perception, he gave the name of *phantasms*, this power of perceiving being the imagination, which with memory constitutes the whole intellectual nature of brutes, while in man it furnishes only the groundwork for the operation of the intellect, which, working on these sensations, reaches first simple and then more complex and general notions. The knowledge thus gained is wisdom; but wisdom as relating to things not concerned with ordinary practice is σοφία, when it regards practice only it is φρόνησις, the quality of both being the same, the difference lying only in the subject-matter. For the connection of the intellect with the soul, see SOUL and THEOLOGY.

Undertow. A current below different from that at the surface.

Underwood. The low woody growths produced among timber trees, sometimes called *coppice wood*, though the term *coppice wood* is more especially applied to woods in which

low growths of shrubs, or the stools of trees, are more abundant than timber trees. [COPPICE WOOD; STOOL.]

Underwriter. Up to the year 1824, all insurance companies, except two which were chartered (the Royal Exchange and London), were prohibited from negotiating marine insurances. The two companies in question, being possessed of a legal monopoly, levied such high rates of insurance, and exercised so rigorous a selection of vessels and voyages, that their business became next to nothing, and the whole system of marine insurance fell into the hands of individuals.

The persons who undertook this important duty, held their sittings just as the Stock Exchange did, at a coffee-house in the city, kept by one Lloyd, and became gradually known as Lloyd's. They could not legally enter into any joint-stock action, since the chartered companies could prohibit such action; and therefore when a merchant or shipowner wished to insure vessel or freight, he negotiated apparently with individuals only, who (acting of course in common) subscribed or *wrote under* the policy of insurance the sums for which they severally bound themselves, in case the ship or cargo were damaged or lost. The association of subscribers to Lloyd's established agencies in most of the principal ports, partly to carry out their business, partly to guard against fraudulent or excessive claims.

When the monopoly of the chartered companies was threatened, the underwriters were alarmed at the risk which they thought they would run from open competition, and employed all the means in their power professedly to bolster up the old monopoly of the two companies, but in reality to deter joint-stock enterprise. These endeavours failed, but the traditional system of underwriting still prevails, though co-ordinately with the establishment of companies which make it their business to grant marine insurances. (*Com. Dict.* 'Abandonment,' 'Average,' 'Jettison,' 'Marine Insurance.')

Undines or **Ondines** (Lat. unda, *water*). The name given by the Cabalists to one class of their spirits of the elements, viz. those residing in the waters. The ancient Greeks believed springs and lakes to be haunted by a race of supernatural nymphs [NAIADS]; and this belief passed down to the middle ages. The Saxons adored the female deity of the Elbe; and the belief in undines is scarcely eradicated in that region. The Saxon peasants report that an undine is often met in the market-place of Magdeburg, dressed as a girl of their own class, but always to be known by having one corner of her apron wet. Near Toulouse many objects of value were once discovered on draining a large artificial lake, which are supposed to have been thrown in as offerings to the spirits of the water. The *nix* of the northern countries and the Scottish *kelpies* belong to the same class of imaginary beings. This superstition has furnished the groundwork of Fouqué's beautiful tale, *Undine.*

Undue Influence. The use of undue influence at parliamentary elections, by intimidating, &c., voters, is now a substantive offence, punishable by a fine of 50*l.*, besides being a ground for avoiding the election. (Stat. 17 & 18 Vict. c. 102 and amending Acts.)

Undue influence exercised by parents over children, &c., is also a ground in equity for rectifying or setting aside dispositions of property and other legal transactions.

Undulation, Point of. In Geometry, a point at which a curve is met by its tangent in four consecutive points. This tangent, therefore, is a triple tangent with coincident points of contact. To the eye such a point presents no singularity, for the curve does not, as at a point of inflexion, there cross over to the other side of the tangent. A point of undulation of higher order is one at which the curve is met by its tangent in any *even* number of consecutive points.

Undulatory Theory. In Optics, the hypothesis according to which the impression of light is conveyed to the eye by the undulations of an elastic medium. This theory supposes the universe to be filled with an ether or medium of great elasticity, but so extremely rare as to offer no appreciable resistance to the motions of the planets. For an explanation of the phenomena of light and colours according to this theory, see LIGHT.

Uneven Number. In Arithmetic, the same with *odd* number; a number not divisible by 2.

Unformed Stars. In Astronomy, such stars as are not included in any of the constellations.

Unguiculate (Lat. unguiculus, dim. of unguis, *a claw*). In Botany, a term exclusively applied to petals which have an unguis or stalk.

Unguiculates (Lat. unguis, *a claw*). The name of a primary division of the gyrencephalous Mammalia, including those which have the digits armed with claws, but free for the exercise of touch upon their under surface. [MAMMALIA.]

Unguis (Lat.). In Botany, the narrow part or *claw* of the base of a petal, taking the place of the footstalk of a leaf, of which it is a modification. *Unguis* is also used as a term of measure equal to a nail, or half an inch, or the length of the nail of the little finger.

Ungula (Lat. *a hoof*). In Geometry, a solid formed by cutting off a part from a cylinder, cone, or other solid of revolution, by a plane passing obliquely through the base. The ungula is, consequently, bounded by the plane of the base, the intersecting plane, and the portion of the surface of the cylinder, &c. included between them. The name is derived from its resemblance to the hoof (ungula) of a horse.

Ungulates (Lat. ungula). The name of a primary division of the gyrencephalous Mammalia, including those species which have

the digits enclosed in hoofs, the under surface not being left free for the exercise of touch. [MAMMALIA.]

Unicorn (Lat. unicornis, from unus, *one*, and cornu, *horn*). The beast called *unicorn* in our version of the Old Testament (Heb. rem), is now commonly understood to be the rhinoceros. But the fabulous unicorn, which has passed into Heraldry, is represented with the figure of a horse, and a single horn issuing from its forehead. The unicorn of Pliny, however, has the head of a hart, the feet of an elephant, the tail of a boar, while the rest of the body resembles a horse. Aristotle, Ælian, and all the classical writers on animals, mention the unicorn. The traveller Ludovicus Romanus asserts that he saw *two* unicorns, kept alive in the temple of Mecca. Many strange virtues were attributed of old to the horn of the unicorn, particularly against poison; but the horns preserved in collections, and to which that name was given, belonged either to the rhinoceros, or to the narwhal or sea-unicorn.

Unicorn Root. The root of *Helonias dioica*, used in North America as an anthelmintic.

Unicursal. In Modern Geometry, a plane curve is said to be *unicursal* when its points can be determined individually, i.e. when the co-ordinates (x, y, z) of each point thereof are proportional to rational and integral functions of a variable parameter θ. Such a curve has the maximum number of double points, viz. $\frac{(n-1)(n-2)}{2}$, where n is its order. The term *unicursal* is due to Prof. Cayley, and is a very convenient one. (*Proceedings of the London Mathematical Society*, Oct. 1865.) Prof. Cayley also employs the term *deficiency* of a curve, to indicate the difference between the number of its double points and the above maximum number. *A unicursal curve*, therefore, *has no deficiency*.

Uniformity (Lat. uniformitas). In the Fine Arts, resemblance in shape between the correspondent parts of a subject.

Uniformity, Act of. In English History, the first Act of Uniformity is 1 Eliz. c. 2; the Act at present subsisting being 13 & 14 Ch. II. c. 4. It regulates the form of public prayers, administration of the sacraments, and other rites of the church of England.

Unigenitus (Lat.). The celebrated constitution, in the form of a bull, issued by Pope Clement XI. in 1713, in condemnation of Père Quesnel's *Réflexions Morales sur le N. Testament*. It is so called from its beginning, *Unigenitus Dei Filius*. Father Quesnel was a friend of the celebrated Jansenist leader Arnauld, and became chief of that religious party after the death of the latter. He died in exile at Amsterdam, in 1679. The bull was procured by the Jesuits, and especially by Le Tellier; it condemned 101 propositions selected from Quesnel's work. Its publication created great discord in France. Most of the bishops accepted it, but with explanations which they gave to the public. Cardinal de Noailles and others refused to accept it all. As soon as the duke of Orleans became regent, Le Tellier was banished, and the party opposed to the bull came into power; but the strength of Rome prevailed, and eventually the duke of Orleans himself compelled De Noailles to accept the bull in 1720. After that event the Janseuist party survived only in small fragments, chiefly among the commonalty of Paris. [JANSENISTS.]

Unilocular (Lat. unus, *one*; loculus, dim. of locus, *a place*). In Botany, seed-vessels not separated into cells. In Conchology, shells which are not divided into chambers.

Unimodular (Lat. unus, and modulus, *a measure*). In Algebra, a term applied to certain transformations and substitutions. [LINEAR TRANSFORMATIONS.]

Union (Lat. unio, *unity*). In British History. The union of the crowns of England and Scotland took place on the accession of James I. to the former. The scheme of uniting the kingdoms was afterwards several times taken up; and commissioners were appointed to consider the subject in the reigns of Charles II. and James II. It was finally carried into execution in 1706, the statute passed on that occasion being the 5 Anne c. 8. By this enactment, laws relating to trade, customs, and excise were to be the same in both countries; other laws to remain in force in each respectively. The parliament of the United Kingdom, called Great Britain, was to have 16 Scottish peers, and 45 members of the House of Commons. The mode of election of peers was subsequently regulated. [PARLIAMENT.]

The union of Ireland with Great Britain was proposed by Mr. Pitt immediately after the suppression of the rebellion of 1798, and it was carried into effect in 1800 by the statute 39 & 40 Geo. III. c. 67 of the British, and 40 Geo. III. c. 38 of the Irish statutes. It admitted 4 Irish lords spiritual, 28 temporal, and 100 commoners to the united legislature; the lords temporal elected for life, the lords spiritual sitting by a certain rotation. By article 5 the churches were united. For the changes which have since taken place in the number of Scottish and Irish members in the House of Commons, see PARLIAMENT.

Union Jack. In Heraldry, the national flag of Great Britain and Ireland. The ancient English flag was the banner of St. George (argent, a cross gules). On the personal union under James I. the banner of St. Andrew (azure, saltier argent) was added (1606). The flag adopted by the heralds after the legislative union (1707) is blazoned azure, a saltier argent surmounted by a cross gules edged of the second. The banner of St. Patrick (argent, a saltier gules) having been added on the union with Ireland, the present flag was thus compounded. It now consists of a red cross of St. George, a red diagonal cross, and a white diagonal cross; the last two being side by

side. The whole are on a blue ground. In addition to being used as an independent flag, it forms the upper quarter next the mast of the red, blue, and white ensigns.

Unions, Trades'. [COMBINATIONS; TRADES' UNION.]

Unionite. The name given to a white Lime-Epidote resembling Soda-Spodumene in general appearance, after the locality, Unionville in Pennsylvania, where it occurs.

Unipeltates (Lat. unus, *one*, and pelta, *a buckler*). The name of a family of Stomapodous Crustaceans, comprehending those in which the carapace is composed of a single shield-like plate.

Uniplanar Node. [NODE.]

Unison (Lat. unus, *one*, and sonus, *sound*). In Music, a consonance of two sounds equal to each other in gravity or acuteness, i.e. sounding the same note.

Unit, Unity (Lat. unitas). In Arithmetic, the number one; an individual of discrete quantity. Euclid defines number to be a multitude or collection of units.

Unit Coil. *Unit of electrical resistance.* A standard measure used by electricians for expressing the amount of resistance experienced in a given electrical circuit.

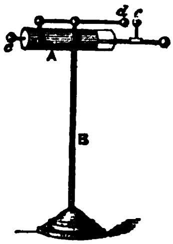
When comparing different electrical circuits, it is as important to be able to reduce the different resistances to terms of some one unit as it is necessary to have one unit of weight and length. One of the earliest units of electrical resistance was that employed by Lenz, who adopted 1 foot of copper wire of a known thickness. In 1843 Wheatstone proposed 1 foot of copper wire weighing 100 grains as a unit. This proposal was succeeded by others from scientific men abroad, each one being founded upon the national weight and length.

The intercommunication and extension of electrical knowledge which followed the introduction of telegraphic wires and submarine cables, rendered it necessary to have some one generally accepted electrical standard as the recognised measure in every country.

To determine what the standard should be, at Prof. W. Thomson's suggestion, the British Association in 1861 appointed a representative committee. This committee agreed upon a system of electrical measurement first proposed by M. Weber, and having many decided advantages. The British Association unit is expressed in ordinary measures, the French being chosen for more general acceptance; and from it can be derived not only the electrical resistance, but the electro-motive force of the current and its equivalent of work.

The unit is known as the B.A. unit, or Ohmad; and is about equal to the mercury unit previously used by Siemen, which is the resistance of a column of mercury 1 mètre long and 1 square millimètre in section at a temperature of 0° C. The B.A. electrical standard is not, however, in general, made of mercury, but of a thick insulated wire, formed of German silver or an alloy of platinum and silver, about 5 feet long, wound into a coil round a hollow bobbin, and the whole covered with an insulating coat of solid paraffin. Precisely to define the B.A. unit is a matter of some difficulty even among electricians, and impossible in a short and general notice like the present. For such a definition and further information, we would refer the reader to Mr. Fleeming Jenkin's report on the new unit, published in the *Proceedings of the Royal Society* for April 1865. A full and popular explanation of *electro-magnetic units* will also be found in Dr. Ferguson's recent and excellent little treatise on *Electricity.*

Unit Jar. A small insulated Leyden jar used for measuring definite quantities of electricity. This instrument was devised by Sir W. Snow Harris, and consists of a small glass jar A, coated inside and outside with tinfoil, and mounted horizontally on a glass rod, B. Attached to the brass wire which connects the inner coating of the jar with an electric machine is a sliding brass ball, *c*. The electricity repelled from the exterior coating is conveyed into the surface to be charged from the ball *e*. When the unit jar is charged to a certain amount, determined by the distance apart of the balls *d c*, a spark passes between *d* and *c*, and discharges the little jar; but being again recharged by the machine, another spark ensues, and so on. By counting the number of sparks and noting the distance between the balls, the number of equal but arbitrary units which have been repelled from the outer coating on to a larger surface (as a large Leyden jar or battery) may be ascertained.



Unitarians. Those who confine the Godhead to a single Person; in which general sense the term may be taken to represent the Arians and Socinians, as well as the sect which is more strictly denominated Unitarian. These last are the descendants of the religious communities which adopted, in the sixteenth century, the opinions of Socinus. They have been supplied with converts from the Presbyterians and Independents in this country, many congregations of whom became first Arian, and latterly Unitarian in sentiment. The principal Unitarian authorities are Drs. Priestley, Belsham, and Channing, who, rejecting the ordinarily received doctrine of the atonement, represent the language ascribed to the apostles upon this and other points as either intentionally accommodated to the ideas current among their hearers, or derived from erroneous conceptions of their own. The Unitarians were subjected to severe penalties, as deniers of the Trinity, long after other dissenters had been relieved by the Act of Toleration: the laws against them were not repealed by statute till the year 1813.

In this country, where they do not constitute

a numerous body, they are principally composed of persons of the educated classes. In Geneva the pulpits of the established church are mostly occupied by professors of these opinions, and in the northern states of America they form an influential Christian denomination.

Unitary Notation. [NOTATION.]

United Brethren. In Ecclesiastical History, a body of reformers in Bohemia, who separated themselves from the Catholics and Calixtines (according to some writers) about 1467. It is also said that they received episcopal ordination from the Vaudois. According to others (Bossuet, *Variations des Eglises Protestantes*, ch. ii.), they were an offshoot from the TABORITES or THABORITES. At all events, it appears certain that there already existed a considerable body of persons professing the tenets of the Reformation in Bohemia at the period of Luther.

United States. It would be inappropriate in this work to give any account of the geographical peculiarities, or of the commercial growth and position, of the United States. For these subjects, the reader may be referred to the *Geographical Dictionary* and the *Commercial Dictionary*. But it appears desirable to say a few words on the constitution of the American republic, and especially on those parts of the constitution the interpretation of which has been, and still is, the subject of earnest debate, and furnishes the material for political action.

The constitution of the United States is written. It may be said, that in general terms the purpose of its framers was the establishment of a political unity in the intercourse which the states might have with other nations, and of domestic independence in the various communities which formed the Federal Union. Great discretion was accorded to the states, in regard to municipal ordinances. They were empowered to contract debts at their discretion; to determine the rights of citizenship; to modify civil rights, as those of marriage, divorce, and the privilege of devising and settling land; to impose internal taxes; and the like. But they were restrained from having an independent army or navy, from imposing import or export duties, and in general from those privileges which have been called *imperial*. [STATE RIGHTS.] It was probably felt that the cohesion of the several states, composed as they were, at and after the War of Independence, of such various, and generally of such discordant, elements, was a matter of great uncertainty, unless the fullest freedom were given to the contracting communities.

Every constitution, even if it be merely traditional, and therefore distinguished only by broad lines, needs an interpreter. But a written constitution, like a dogmatic confession of faith, invites scrutiny and criticism, is sure to be variously understood whenever interests are conflicting, and is certain to be strained when any political party is eager and able to administer it. The difficulties which belong to a traditional constitution are sure to be exaggerated when the institution is defined by positive enactments, especially when those enactments were compromises, forced on the contracting parties for common ends and by common dangers. The prospect of these differences and difficulties has always been present to the American people, who have thereupon treated the constitution with an almost superstitious reverence. No one, however, could have doubted, that at some time or other conflicts would arise between the Northern or free states, and the South or slaveholding communities, although the former were patient under the continual political ascendency of the South, and the latter did not, except on rare occasions, quarrel with or contest the protectionist policy of the North. It was easy, however, to foresee that the apparent harmony of the states was only an armed truce, and that sooner or later dissension would break out; nor was it difficult to predict that this hostility would take the form of a struggle between the slavery and the free-soil parties. As we know now, these differences culminated in the election of Mr. Lincoln, i. e. in the total defeat of the party which desired to extend slavery into the territories, in the secession ordinances of 1861, and in the four years' war.

The difficulties, however, which attend the interpretation of the American constitution have only now begun. The party of amnesty, i. e. the Democrats, and the party of reconstruction, i. e. the Republicans or Radicals as they are now called, equally appeal to the written constitution, as supporting courses of policy diametrically opposed to each other; and as the differences are not speculative, but practical, the decision arrived at at last can scarcely fail to put so new an interpretation on the terms of the document which constitutes the Union, as to make the gloss, whatever it be, a new clause or a new set of clauses in the instrument itself. One thing at least is certain, that the congress will henceforward assume a far more important position in the public life of the American people, and that it will tend more and more to dwarf and curtail those state rights the independence of which has formed so singular a characteristic in the American federation. The reconstruction of the Southern states is in effect the reconstruction of the Union, since it is hardly possible to impose conditions on those communities without implying a similar supervision over the municipal arrangements of the other states. Nor is it likely that the supreme court, with which rests ultimately the decision as to the legality of acts, and their accordance with the constitution, will oppose a permanent or effectual barrier to the purposes of the successful parties in that great civil struggle which has succeeded to the civil war; for it may be laid down as a general maxim in politics, that judicial opposition may retard, but can never arrest, political changes.

Unities. In the Drama, there are said to be three unities—of time, place, and action.

The latter only is strictly adhered to in the Greek drama; but the drama termed *classical* by the moderns (in opposition to the *romantic*) requires all three. [DRAMA.]

Univalve (Lat. unus, *one*; valva, *a valve*). This term is applied to those Molluscs the shell of which is composed of one piece, and which is generally convoluted spirally. Latreille also thus denominates a family of Lophyropodous Crustaceans.

Universal (Lat. universalis). In Logic, a universal proposition is that which has the subject distributed, so that the predicate is declared concerning everything comprehended in it; e. g. 'All men (subject) are mortal (predicate).' In universal negative propositions the predicate is distributed also; e. g. 'No men are immortal.' For the nature of Universals, see LOGIC, PROPORTION, SYLLOGISM.

Universal Joint or **Hooke's Joint.** In Machinery, an ingenious contrivance of Dr. Hooke, for the purpose of enabling the end of a shaft or suspended rod to be moved in any direction as freely as if the junction were by a ball-and-socket joint, while the shaft will nevertheless be able to communicate through the joint the force of torsion. The universal joint is virtually two hinges set in the same plane, one of which permits motion in one direction, and the other in a direction at right angles thereto; and by the combined motion of the two, the end of the shaft or rod may be made to describe a circle or any other figure. By this expedient, connected lengths of shafts may be made to rotate, though they are not in the same right line. The universal joint is either single or double. In the single universal joint, the two shafts or axles, A and B, between which the motion is to be communicated, terminate in semicircles, the diameters of which are fixed in the form of a cross, their extremities moving freely in bushes placed at the extremities of the semicircles. Thus, while the central cross remains unmoved, the shaft A and its semicircular end may revolve round CD as an axis; and in the same manner B, with its semicircular end, will revolve round E F. If the shaft A be made to revolve without changing its direction, the point C D will move in a circle whose centre is at the middle of the cross. The motion thus given to the cross will cause the points E F to move in another circle round the same centre, and hence the shaft B will be made to revolve.

Fig. 1.

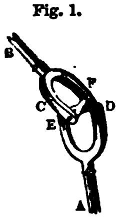


Fig. 2.

When the shafts are inclined to each other under an angle of 40°, it is necessary to employ a double universal joint, as represented in the annexed figure. In this manner the motion may be transmitted from one shaft to another at right angles. Instead of employing a cross in the manner now described, the joints may be constructed with four pins, fastened at right angles upon the circumference of a hoop or ball. Universal joints are of great use in cotton mills, where the tumbling shafts are continued to a great distance from the moving power; for, by applying a universal joint, the shafts may be cut into convenient lengths, and so be enabled to overcome a greater resistance.

Universal Language. More than one attempt has been made to contrive a system of writing that should be universally intelligible. As this writing would represent sound, the sounds, if uttered, would form a universal language. But the latter purpose is not necessarily involved in the former. The best known effort of the kind is perhaps that of Bishop Wilkins, who asserted that 'if to every thing and notion there were assigned a distinct mark, together with some provision to express grammatical derivations and inflexions, this might suffice as to one great end of a real character—namely, the expression of our conceptions by marks which shall signify things and not words.' It follows that a universal classification must precede the formation of such universal language, and to have any value this classification must be permanent, i. e. it must not need alteration owing to the acquisition of new information; in other words, universal knowledge seems to be an indispensable condition for the formation of universal language. Such attempts may therefore be regarded as the efforts of men sitting in judgment on the whole realm of human knowledge and dreaming that they have mastered it. The classification proposed by Bishop Wilkins is given by Prof. Max Müller in his second series of *Lectures on Language*, ii.

Universalists. A name by which the Arminians are sometimes characterised, as expressing the universality which they attribute to the operation of grace, conceiving it to be given to all men without favour or reserve. On the other hand, the Calvinists, or those who hold the particular election of individuals, are designated as Particularists. The name is also applied by some to those who maintain that as God desires the highest welfare of all His creatures, so He will ultimately bring them to it.

University. In the middle ages, the Latin term *universitas* signified the whole body of students, or of teachers and students, assembled in a place of education, with corporate rights, and under by-laws of their own; in later times, also, the name was held to imply that all branches of study were taught in a university. In the modern sense of the term, a university signifies an establishment for the purposes of instruction in all or some of the most important divisions of science and literature, and having the power of conferring certain honorary dignities, termed *degrees*. It is generally understood that the authorisation of the sovereign power in the state is necessary to enable such an establishment to confer degrees; and, in most European countries, there are various offices and

professional situations for which a person is qualified by having taken a certain degree at one of these establishments. Hence universities, although in many instances they are composed of private foundations, are justly regarded as national institutions. The university of Paris, the most celebrated of those of the middle ages, and which served in some degree as a model to the rest, was formed about A. D. 1200 by the union of the various schools of rhetoric, theology, and philosophy, with which that city abounded, under one head, styled the *rector*. That university was divided into four nations—French, Picard, Norman, and English: the first comprehending students from Italy and Spain, the last from the north of Europe generally. The subjects taught were arranged under faculties; viz. theology, law, medicine, and that of the seven liberal arts, rhetoric, logic, grammar, geometry, arithmetic, astronomy, music. [QUADRIVIUM; TRIVIUM.] These faculties were corporate, and each elected a dean; and the deans, with the procuratores of the nations, represented the university. The lowest degree was that of *bachelor*; the next, *licentiate*; the third, *magister* (this degree at Paris corresponding with that of *doctor* at Bologna). The colleges were royal or private foundations for the benefit of poor students, whose board was, in some instances, found for them, and who received stipends or other emoluments. The faculty of theology at Paris was well known by the name of the SORBONNE. This slight sketch of the constitution of the famous university of Paris may serve to describe similar establishments in Continental countries during the middle ages, and down to a comparatively late period. In England, the two national universities have been established, from a period of considerable antiquity, at Oxford and Cambridge. The original constitution of these universities much resembled that of the Parisian, with the exception of the division into four nations, which was wanting. But their subsequent history was modified by the growth of the colleges, or individual foundations, into a much higher degree of consequence. These were originally destined by their founders merely to entertain a certain number of junior students (generally termed *scholars*), and a higher body (named in most cases *fellows*), and to furnish them with assistance in the prosecution of their studies; while the great body of independent students lodged in the numerous halls, and attended only on the public university lectures. But by degrees the colleges likewise became receptacles for independent students, under the tuition of the fellows; the halls were for the most part abandoned, while such as remained partook of the collegiate character; and, in the modern system (which has subsisted for more than two centuries), no student is admitted to take a university degree unless he has completed his studies in a college, or collegiate hall, under the superintendence of its tutors. The degrees, in Oxford and Cambridge, are differently named, or arrived at in different succession, in the several faculties; but degrees in theology and medicine can be obtained only after the acquisition of certain degrees in arts.

In the English universities, as in those on the Continent, the industry of students has from an early age been aided by foundations, created by public or private munificence. The practice of endowing *exhibitions* or pensions for scholars (in mediæval Latin *bursæ*, whence the German bursche for a student), has been almost universal in Europe. Confining ourselves to the universities of Oxford and Cambridge, we find the following results. The several endowments established for the benefit of scholars may be classed either as *university* or as *collegiate*.

University Scholarships.—These are given, generally speaking, to students already established at the universities, as rewards of merit in classics, mathematics, divinity, and other special subjects. There are at present about 40 university scholarships at Oxford—about 25 at Cambridge—with emoluments varying from 75*l.* per annum (the Craven scholarships at both universities attain this sum) to inferior amounts. They are attainable for the most part by undergraduates, and are held only for a few years. There are also many exhibitions, attached to public and grammar schools, which are given after open competition to members of those schools on their departure for the university, to be held by them during a specified time, which is generally limited to the number of terms necessary for obtaining the first, or Bachelor's, degree in Arts.

University Fellowships are very few: the most remarkable, the Radcliffe *travelling fellowships* at Oxford, were created to advance the acquisition of classical and other knowledge through foreign travel.

But the collegiate endowments, for the benefit of students, are of far more importance than those which appertain to the university in general.

According to the ancient system, the founder of a college at Oxford or Cambridge, whether the crown or a private individual, endowed it with sufficient means to maintain a head (principal, master, warden, &c.), a certain number of fellows, and a certain number of scholars. These were appointed under an infinity of private statutes; preference (absolute or comparative) being given to persons educated at particular schools, natives of particular parts of England, *founders' kin*, and so forth. While in the lapse of time the foundations at Oxford retained their strictly exclusive character, those at Cambridge became more open; the ordinary rule at the latter university being that *scholarships* were open to the most deserving competitors, *fellowships* to the most deserving members of the college, unless the fellows thought proper to elect from the university at large. These ancient institutions were, however, remodelled after long and careful enquiries by commissioners, in the present reign. The collegiate foundations at Oxford are now governed by the statute 17 & 18 Vict. c. 84 (passed in

1854), and under the forms thereby given to the authorities of the several colleges. Cambridge is regulated by the body of university statutes, confirmed in 1858.

The general result, as regards foundations in the colleges of Oxford and Cambridge for the benefit of students, may be thus summed up. They are divided into—

1. *Sizarships, Servitorships, &c.*—Endowments especially for the benefit of poorer students; formerly connected with inferiority of position, which modern improved feeling has nearly removed.

2. *College Scholarships.*—These are very numerous in both universities, and are for the most part attainable by open competition, by students on their first admission to the university; lasting generally until the degree of B.A. or somewhat later: with endowments varying, according to the wealth of the several colleges, from nearly 100*l.* to much lower amounts per annum.

3. *Fellowships.*—The highest and most important order of college endowments. The number of these has been considerably reduced by recent reforms.

There are, at present, 385 fellowships in the colleges of Cambridge: about 350 at Oxford (including the senior studentships of Christ Church). The great majority of these are now attainable by open competition, by members of the university who have attained the degree of Bachelor of Arts. The exceptions at Oxford are chiefly that at New College some preference is given to persons educated at Winchester; and that at All Souls the competition is limited in a particular manner, which has formed the subject of a recent judgment of the Privy Council in favour of open competition (1864). The larger colleges at Cambridge still elect to fellowships by competition in their own body. The value varies from 300*l.* and upwards per annum, to much lower amounts. The tenure of fellowships was, until recent reforms, altogether confined to the unmarried, and chiefly to those who intended to adopt the clerical profession; but at Cambridge the general rule may now be said to be that fellowships last for ten years, and are not determined by marriage; each college, however, at both universities, has its own rules.

The university of Paris was suppressed in 1790. The present university of France was instituted in 1808, and embraces the whole empire. It is subdivided into twenty-seven academies, each governed by a *recteur* and *conseil académique*. In Spain, the universities are arranged on a system somewhat resembling that which prevails in England, the students being entered of their respective college in each. In Germany, as in England, the earliest universities (Prague, founded in 1348, and Vienna, in 1365) were framed on the model of that of Paris. Germany has now a far more numerous list of universities than any other country. But the collegiate system never prevailed in that country as among ourselves. On their present arrangement (which is pretty similar in all, Catholic as well as Protestant), the four faculties are retained. Professors in the various branches are appointed by government. These form the senate, at the head of which is the pro-rector, who is chosen annually or biennially. Besides these, there are extraordinary professors, who receive small salaries, and an inferior class of licensed teachers, or licentiates, who receive none. The professors are obliged to give public lectures in the branch of study to which they are appointed; but they, as well as the other two classes, may give also private lectures on whatever subject they please; and from the fees of attendance at these lectures their principal income is derived. The student is for the most part left at liberty to attend what lectures he pleases; but licenses to practise various professions, benefices in the various churches, &c. are given, especially in Prussia, only to those who have studied a certain number of years by attending lectures in the requisite branch of study. The constitution of the Scotch universities has a great resemblance to those of Germany; and the same remark is applicable to the London University. A great mass of information with respect to ancient and modern universities, will be found in the *Encyclopædia Britannica*, 8th ed. 1860, art. 'University.' See, too, Savigny, *Hist. of Roman Law*, vol. iii. For an elaborate defence of the English system, see *Quart. Rev.* vols. lii. lix.

Univocals or **Synonyms.** In the Aristotelian Logic (as used by the schoolmen), generic words; i.e. words of which both the genus and the difference are predicable of many different species; e.g. the genus *animal* is *univocum univocans* with respect to *man* and *brute*, both of which are comprehended under any definition which can be given of the word *animal*, and are called with reference to it *univoca univocata*. *Universal* terms are also such as have only one signification; opposed to *equivocal*.

Unproductive Consumption. In Political Economy, a term used by some writers to denote that expenditure which has no relation, either directly or indirectly, to the replacement of the capital employed on it. It may, of course, happen that consumption may be productive in one case, and the contrary in another. The idle amusements of this person may be the necessary recreations of that; the luxurious expenditure of some may be the business of others. Nor does it follow that unproductive consumption is an economical evil. The taste for enjoyments is an unquestionable stimulus to activity, and those communities make but little progress in wealth whose habits are rude, unrefined, and exceedingly parsimonious. But all waste which may be avoided is in a full sense unproductive consumption, whether it be waste of capital, waste of labour, or waste of life.

Unstable Equilibrium. [STABLE AND UNSTABLE EQUILIBRIUM.]

Upádána. In the Buddhist Theology, upádána (or the attachment to existence) forms

with karmma (*work*) the cause of all causes and the source from which all beings have originated in their present form. All beings are produced from the upádána of some previous being, while karmma is the aggregate action which by virtue of its existence it must produce. This is only another way of stating the doctrine of necessity; but instead of seeking happiness by ignoring a law confessedly inevitable and unknown, the Buddhist deduction is that the duty of man is to kill the law by uprooting the upádána or attachment to existence, all evil being produced directly from this cause. The object of the Buddhist philosophy is the attainment of perfect calm, in which the man may cease to be conscious of being. The state thus attained is nirwan, or nirvana, which some suppose to be absorption into the supreme all-pervading deity; others to be a mere nonentity, there being no supreme deity into which being may be absorbed. In this philosophy the idea of sin is inadmissible, everything being in itself indifferent, and the so-called badness of a thing being dependent entirely on the injury resulting from it to another. The practical result of such a system, if free from all judgments and drawbacks, would be a general passive benevolence, active well-doing being by the hypothesis of no use whatever. (R. S. Hardy, *Legends and Theories of the Buddhists*.)

Upas-tree (Upas, the Javanese name). A tree common in the forests of Java and some of the neighbouring islands, to which extraordinary stories, for the most part fabulous, have been attached. Upon the authority of Dutch writers, it has been asserted that it is a most deadly poison employed in the execution of criminals, who are, however, pardoned if they succeed in reaching a tree and bringing back its venom. Birds were said to drop dead while flying over it, and the whole country round it was asserted to be desolated by its pestilent effluvia. The truth is, that the Upas-tree is merely a tree with poisonous secretions, and nothing more; there is nothing deleterious in its atmosphere. It is an Artocarpaceous plant, called *Antiaris toxicaria*, and is very nearly related to the fig, some of the species of which are also deadly poisons. [ANTIARIS.]

Uphers. In Architecture, fir poles chiefly used in scaffolding; they run from twenty to forty feet in length, and from four to seven inches in diameter.

Uphroe. On Shipboard, an oblong block, without sheaves, and having several holes. Its use is to hold ropes temporarily extended: the formation preventing the rope from slipping.

Uplands. Lands on hills or steep declivities, which in general require a different kind of management from lands in plains or comparatively flat surfaces. Uplands are generally kept in pasture or underwood.

Upper Eocene. These beds are almost wanting in England. The Hempstead and Bembridge series of the Isle of Wight have recently been referred to them. In France, the Fontainebleau sands form the base, but the main developement is in a vast and varied series of fresh-water and lacustrine sandstones, marls, and millstone-rock. These occupy large tracts in Central France, especially in the Auvergne district, and also in the basin of the Rhine at Mayence and various points. The French deposits reach up to the valley of the Seine. The Limburg beds of Belgium are referred to the same division of the older tertiaries. Some of the German brown-coal is of this date.

Upper Greensand. A calcareous sandstone often coloured green by particles of silicate of iron, and often passing into hard clayey bands. As a characteristic rock deserving its name, it is confined to the south-east of England. In Surrey, parts of it are worked for lining furnaces and sold as *firestone*. A little farther west, it passes into what is locally called *Malm Rock*, and a rock of the same kind and the same age is seen at Blackgang Chine in the Isle of Wight, where it is 400 feet thick, the upper part cherty and the lower sandy. It is well seen in Dorset and North Wiltshire, but becomes less important as it is traced below the chalk in Bedfordshire and Cambridgeshire. It is rich in nodules of phosphate of lime. [COPROLITES.]

Upupa (Lat. upupa, Gr. ἔποψ, *a hoopoe*). A genus of Tenuirostral Passerine birds, distinguished by an ornamental head-crest formed of a double range of feathers, which can be erected at will. The common hoopoe (*Upupa epops*) is an occasional but rare visitant of England.

Urachus (Gr. οὐραχός). The ligamentous chord which arises from the base of the urinary bladder, and terminates in the umbilical chord.

Ural Mountains. This low chain, unimportant enough in some respects, is interesting as the only interruption to the level of the great northern plain of the Old World. It is entirely unconnected with the main chains of Asia, and may be traced from between the lake of Aral and the Caspian Sea, as far as the northern extremity of Nova Zembla in the arctic circle, a distance of nearly 2,000 miles. As a chain, however, it begins only in about 50° north lat. It is about the height of the Vosges mountains in Eastern France, and nowhere reaches 3,500 feet. It is wooded to the top, and is singularly rich in mineral wealth of all kinds, its gold, copper ores, and iron ores having long been extensively worked.

The Ural chain serves as the dividing line between Europe and Asia, but it rises so gently, and the passes across it are so low, as to be almost unnoticeable. Extensive marshes occur on the Siberian side. There are no precipices or gorges connected with it; but Sir R. Murchison describes some real mountain scenery not unlike that of Wales and Scotland in the part of the chain called the *Katchkanar*. The geological age appears to correspond.

Uralite. A pseudomorphous form of Hornblende after Augite, which is found in the augitic porphyry of the Ural.

Uralorthite. A variety of Orthite, found in the flesh-coloured Felspar of Minsk in the Ural.

Uramile. A white or pinkish crystalline body, the product of the decomposition of thionuric acid by heat. It contains $C_8 H_5 N_3 O_6$.

Uran-mica. [URANITE.]

Uran-ochre. [ZIPPEITE.]

Uranbloom. [ZIPPEITE.]

Urangreen. A native sulphate of copper and uranium, which is found in green acicular crystals and crusts at Joachimstahl in Bohemia.

Urania (Gr. οὐρανία). In the Hesiodic *Theogony*, Urania is mentioned as one of the nine Muses, the children of Zeus and Mnemosyné, and also as a daughter of Oceanus and TETHYS. For the meaning of the name, see URANUS.

URANIA. A synonym of *Ravenala*, a magnificent palm-like genus of *Musaceæ*, confined to Madagascar, where it is called the Traveller's-tree, because the leaves when cut yield an abundant and refreshing juice, with which travellers allay their thirst. The plant does not seem indigenous to Mauritius, as stated by some, but groves of it have been planted in the botanic gardens of that island. The leaves are of gigantic size, somewhat like those of *Musa Ensete*, but arranged in two rows on opposite sides of the arboreous stem.

Uranite or **Uran-mica.** Native phosphate of uranium and lime. It occurs nearly always in tabular crystals of a siskin-green to a yellow colour, and differs from Mica in being neither flexible nor elastic. Uranite is found in France at St. Yrieux near Limoges, and in Saxony.

Uranium. A metal discovered by Klaproth in 1789, who named it after the planet Uranus, discovered about that time. It occurs in the minerals *uranium ochre* $U_2 O_3 HO$; *pitchblende*, which consists of the black oxide $U_4 O_5$ associated with silica, lead, and iron; *chalcolite*, *uranglimmer* or *uran-mica*, which consists of the phosphate of copper and uranium, $Cu O$, $2 U_2 O_3$, $P O_5$, $8 H O$, and *uranite*, which is the phosphate of lime and uranium, $Ca O$, $2 U_2 O_3$, $P O_5$, $8 H O$.

Little is known of the properties of metallic uranium: it appears to be a slightly malleable whitish metal, of the specific gravity about 9. The salts of the oxides of uranium are of a green or yellow colour: the persalts have been most examined. Ferrocyanide of potassium produces in them a very characteristic rich brown precipitate, not unlike that formed by the persalts of copper. They are also precipitated brown by infusion of galls. Peroxide of uranium is used to give a green or greenish-yellow colour to glass, and a suboxide ($U_4 O_5$) is used in porcelain painting for the production of an intense black. The equivalent 60 has been assigned to uranium.

Uranochalcite (Gr. Οὐρανός, and χαλκός, *copper*). A Mineralogical synonym for Urangreen.

Uranoniobite. A name for the crystallised Pitchblende from Stromsheim in Norway.

Uranoscopus (Gr. οὐρανοσκόπος, *watching the heavens*). A genus of fishes was so called by Linnæus, because both eyes were placed on the superior surface of the head, which presents a nearly cubical form. The mouth is cleft vertically at the anterior part of the head, and, like the eyes, is directed upwards. The species of this genus commonly called *star-gazers* belong to the *Percoid* family of Acanthopterygian fishes in the Ichthyological system of Cuvier.

Uranus (Gr. Οὐρανός). In Astronomy, the remotest known planet, except Neptune, belonging to our solar system. The mean distance of Uranus from the sun is 19·18239, that of the earth being considered as unity, whence its real distance is upwards of 1,800 millions of miles. Its sidereal revolution is performed in about 84 Julian years. The orbit is inclined to the ecliptic in an angle of only 46′ 28·4″; and the eccentricity of the orbit is 0·046679, half the major axis being taken as unity. The apparent diameter of Uranus (which, on account of the great magnitude of its orbit in comparison of that of the earth, undergoes very little variation) is about 4″; whence the real diameter of the planet must be about 35,000 miles, or nearly four and a half times that of the earth; and its bulk about eighty times that of the earth. Uranus presents the appearance of a small round and uniformly illuminated disc, without rings, belts, or discernible spots. From analogy, we infer that it revolves about its axis; but of this there is no direct proof: the great distance of the planet, indeed, precludes our obtaining much knowledge of its physical state.

Only two satellites of Uranus are known with certainty, although the existence of four at least is suspected. [SATELLITE.]

Uranus was discovered by Sir William Herschel, at Bath, on March 13, 1781. It had been previously observed by Flamstead, Bradley, Mayer, and Lemonnière in their ordinary star-observations; but, owing to the inferiority of their telescopes, not one of these astronomers suspected it to be a planet. Sir W. Herschel called it the *Georgium Sidus*, in honour of George III. Foreigners for some time called it *Herschel*; and it is now, in some English works, called the *Georgian*. [PLANET.]

URANUS. In the Hesiodic *Theogony*, Uranus or Ouranos (the Latin Cœlus) is a son of Gaia, *the earth*; but he is also called her husband. This is, however, one of the names which had not lost for the Greek their original meaning. Ouranos is called by the Hesiodic poet, *the starry*, and he is said to cover all things. This takes us at once to the Sanscrit Varuna, a name of the firmament, from the root *var*, to cover. The name thus belongs to the same class with ENDYMION, SELENE, TELEPHASSA, &c. Among the children of Ouranos, are HYPERION, TETHYS, and Cronos; but as he was in the habit of banishing his children to TARTARUS, he was unmanned by Cronos, and from the drops of his blood sprang the Gigantes, and APHRODITE, the

child of the sea-foam, i.e. the dawn arising [ANADYOMENE] out of the sea. This myth is repeated in the case of Cronos, who is described as devouring his children after their birth; and in each case it simply means the disappearance of each day, with its sun and its light, its morning and evening, in the abyss of the past. Ouranos, then, is the mighty being whose dwelling is spread over the whole heaven, and who broods over the earth with an unfailing, life-giving love. Hence his offspring is as manifold as that of HERACLES, with whom, as well as with Zeus, his character is almost wholly interchangeable, even in Greek mythology. Heracles (*the sun*) journeys over all lands, and wherever he goes, a rich harvest follows, and noxious things disappear; but the tales of Ouranos, Zeus, and Heracles all become more or less coarse and repulsive, and for the same reason. That which may be said, with beauty as well as with truth, of the heaven (Ouranos), of the sky (Zeus), and of the sun (Helios or Heracles), will not bear translation into the conditions of human life, without degrading the spiritual god into a being who boasts of his unbounded and shameless license. Hence, as the gods become more and more anthropomorphised, the ideas of personal purity and goodness are transferred from Zeus to PHŒBUS, and his sister Athênê. [TRITOGENEIA.]

Uranvitriol. [JOHANNITE.]

Urao. Native sesquicarbonate of soda, found at the bottom of a lake in Macaraibo, in Columbia.

Urceola (Lat. urceolus, dim. of urceus, *a pitcher*). Of this genus of *Apocynaceæ*, the only species, *U. elastica*, a climbing milky-juiced shrub or tree, frequently with a trunk as thick as a man's body, is found in Borneo, Sumatra, and other islands of the Eastern Archipelago. It yields a milky juice, which is collected by making incisions in its bark, or by cutting the trunk into junks, and forms one of the kinds of Caoutchouc called Juitawan; but, owing principally to want of care in its preparation, this Eastern caoutchouc is inferior in quality to that of South America, the milk being simply coagulated by mixing with salt water, instead of being gradually inspissated in layers on a mould. The plant bears many-flowered terminal cymes of small greenish blossoms, which produce double fruits, consisting of two large roundish apricot-coloured rough leathery-skinned parts about the size of oranges, containing numerous kidney-shaped seeds nestling in a copious tawny-coloured pulp, which is much relished both by natives and European residents, and is said to taste like well-bletted medlars.

Urceolate. In Botany, a term applied to that form of corolla which is shaped somewhat like a pitcher with a contracted mouth.

Urdite. [MONAZITE.]

Urea. This substance is the characteristic ingredient of the human urine, and that of the greater number of carnivorous animals. It is a highly azotised substance, represented by the formula $C_2H_4N_2O_2$. It may be obtained by carefully evaporating urine to the consistency of a thin syrup, filtering and adding an equal volume of pure nitric acid; a crystalline precipitate of *nitrate of urea* gradually forms, which, decomposed by carbonate of baryta, yields nitrate of baryta and urea, from which boiling alcohol dissolves out the urea. An *oxalate of urea* may be similarly formed, and decomposed by carbonate of lime into urea, and oxalate of lime. Urea may also be formed artificially in various ways; thus Wöhler obtained it by the careful evaporation of a solution of cyanate of ammonia, a salt which is metameric with urea,

$$\underbrace{NH_4O, C_2NO}_{\text{Cyanate of ammonia}} = \underbrace{C_2H_4N_2O_2}_{\text{Urea}}$$

Urea crystallises in prisms; of a cooling saline taste: it is soluble in water and alcohol; but insoluble in ether and in an excess of nitric acid. It is neither acid nor alkaline. Pure urea is permanent in the air; at 250° it fuses, at a higher temperature it yields ammonia, cyanate of ammonia, and cyanuric acid. When heated in close vessels to between 428° and 464°, it is converted into carbonate of ammonia and water. An aqueous solution of urea remains long without change; but the addition of proteiniferous substances resolves it more rapidly into carbonate of ammonia. In this case 1 atom of urea, and 4 atoms of water, yield 2 atoms of carbonate of ammonia: $C_2H_4N_2O_2 + 4HO = 2(NH_4O, CO_2)$.

The proportion of urea contained in urine is very variable, as will appear by Dr. Golding Bird's analysis. [URINE.] It is increased by exercise, and diminished by rest. Urea has been detected in the blood, and, where the kidneys are extensively diseased, may so accumulate there as to produce a form of narcotic poisoning known under the name of *Uræmia*.

Uredo (Lat. from uro, *I burn*). A genus of microscopical *Fungi*, the presence of which is known by the burnt appearance of the part infested by them. They consist of extremely minute brown protospores, which multiply with great rapidity, and appear to injure plants by absorbing their juices. The species formerly included in *Uredo* are many of them referred to other genera, and the old group *Uredo* rather represents the modern *Uredinei*. Smut or dust-brand, a disease too well known to the farmer, was once thought to be occasioned by attacks of *Uredo*, but the minute fungus which causes that affection is now referred to the genus *Ustilago*. Steeping corn in a solution of blue vitriol is the means resorted to by agriculturists for repelling these attacks. A pound of blue vitriol dissolved in two gallons of water may be thrown on eight bushels of wheat, and the whole being turned over so that the surface of every grain in it is wetted, it will dry of itself in an hour or two, and be fit for sowing. The germs of the destructive fungus with which the dressing comes in contact, are thus destroyed; but from the economy of its growth, botanists consider that

little if any result follows as regards the immunity of the crop.

Ureter (Gr. οὐρητήρ). The membranous tube which conveys the urine from the kidney to the urinary bladder.

Urethra (Gr. οὐρήθρα). The membranous tube or canal by which the urine is voided.

Urginea. A genus of *Liliaceæ*, closely allied to *Scilla*. The species which are natives of the Mediterranean region, and have large bulbs, as in the case of *U. maritima*, the old *Scilla maritima*, are known in medicine as Squills. These bulbs are imported from Malta and elsewhere, some having white scales, while others are of a darker colour, the lighter sort being preferred by druggists. It has been supposed that the Red Squills are the produce of another species, *U. Pancration*, but this seems doubtful. Fresh squills are very acrid, causing irritation, and even vesication, of the skin; the drug is, however, usually imported in the dried state, when its acridity is in great measure decomposed. The bitter taste of squills is due to a substance called *scillitin*. Squills are used in medicine as a diuretic in certain forms of dropsy, and as an expectorant in coughs. [SCILLA.]

Uria (Gr. οὐρία). A genus of web-footed birds, belonging to the short-winged family (*Brachypteres*, Cuv.), and, like the rest of that family, admirable divers. The species of *Uria* are all marine, and generally known by the name of *Guillemots*. They resort in vast numbers to breed among the rocks of the Orkney and Shetland Isles, and are a source of profit to the adventurous inhabitants.

Uric Acid. An acid peculiar to the urine of certain animals; it is always present in human urine, and in the excrements of many birds of prey and of serpents, especially of the *Boa constrictor*, which is voided in white nodules, consisting of little else than urate of ammonia. Uric acid also forms one of the commonest varieties of urinary calculi (hence the term *lithic acid* applied to it), and of the red gravel or sand which is voided in certain morbid states of the urine. Pure uric acid is obtained in the state of a very insoluble white powder by digesting the excrement of the boa, in potash, and dropping the solution into weak hydrochloric acid: the precipitate which falls is to be well washed, and dried at 212°. Its most distinctive chemical character, by which it is at once easily recognised, is, that when moistened with nitric acid and heated it dissolves, and upon evaporation to dryness leaves a red compound, which, upon the addition of a drop or two of a solution of caustic ammonia, becomes of a fine crimson. The composition of uric acid is represented, in reference to its dibasic character, by the formula ($2HO, C_{10}H_2N_4O_4$).

Uric acid requires about 10,000 parts of water for solution, and the greater number of the *urates* are also of very sparing solubility: the most soluble among them is the *urate of lithia*, and lithia water has accordingly been suggested, as preferable to soda or potash water, in cases of gout, gravel, and other disorders connected with excess of uric acid.

Uric acid is remarkable for the number of definite compounds which may be derived from it by various oxidising agents, the products differing with the agent employed. These were first accurately investigated by Liebig and Wöhler, and are important in their physiological and therapeutic bearings, and in reference to the theoretical views which have been founded upon them. Details upon these subjects would be foreign to the purpose of this Dictionary; but some idea of the number, nomenclature, and elementary composition of the derivatives of uric acid may be formed from the following tabular view of them given in Miller's *Chemistry* (2nd edit. vol. ii. p. 732), where also will be found a succinct account of the production and properties of the compounds.

Uric acid . .	$C_{10}H_4N_4O_6$
Urea . . .	$C_2H_4N_2O_2$
Alloxan . .	$C_8H_4N_2O_{10}$

Urim. A word connected in its signification with the word *thummim*, being the plural of the Hebrew aur, *a light*, *a luminary*; whence it has come to signify fire. *Thummim*, which is the plural of thom or tam, means *fulness* or *perfection*. See Wilkinson's *Ancient Egyptians*, as to the connection of this word with the title of the Egyptian god Thauth or Thoth.

The two words, conjointly, signify *light* and *perfection*; but the Septuagint render it literally δήλωσις καὶ ἀλήθεια, *manifestation and truth*. The urim and thummim are described as the precious stones on the high priest's breastplate, which were supposed to make known the will of God by casting an extraordinary lustre, and thus to *manifest* the success of events to those who consulted them.

Urine (Gr. οὖρον; probably akin to Sansc. vâri, *water*). The fluid secreted by the kidneys, whence it passes by the ureters into the bladder. The variable appearance of the urine announces, even to the casual observer, corresponding fluctuations in its composition; these have long been studied by physicians and medical chemists, as furnishing useful prognostics in disease. The chemical analysis of the urine is attended by many difficulties, arising out of the

number of substances which are found in it, the variations in quantity and quality to which they are liable, and the facility with which they are modified by reagents and by spontaneous changes. The substances found in healthy urine are water; carbonic, phosphoric, hydrochloric, and sulphuric acids; potassa, soda, lime, magnesia, and ammonia. The characteristic organic substances in such urine are urea, and uric acid, together with mucus, and colouring and odorous matters. To these may perhaps be added benzoic, hippuric, lactic, and acetic acids, and traces of hydrofluoric acid, and silica. In certain diseases other products make their appearance, which are not discoverable in healthy urine; such as oxalic acid, nitric acid, sugar in quantity, albumen, cystic oxide, and occasionally some organic compounds, the nature of which has not been satisfactorily ascertained.

When the urine is in a healthy state, there are many circumstances of mind and body which materially influence its appearance and quantity. After very copious draughts of diluting and diuretic liquids, or in hysteria and in some phases of Bright's disease, it is little else than water; at other times it is saturated with its solid contents, and even deposits part of them as it cools. If turbid at the time when it is voided, it may always be considered as in a morbid state. Sometimes it contains foreign matters which have been taken as medicine or food. The peculiar odour imparted to it by asparagus, the colour induced by spinach, rhubarb, &c., and the passage of certain saline substances by the kidneys, are familiar cases of the presence of such foreign matters in the urine. The daily average of urine voided under ordinary circumstances, by healthy individuals, is about 40 ounces; and its specific gravity should not exceed 1030; though in some cases of disease, as in diabetes, it rises to 1050 or more. The usual average is 1020. It always reddens litmus, which indicates free acid. In cases of suppressed perspiration its quantity is usually increased; and when the perspiration is copious, it is diminished. It is one of the great outlets of mere water from the system. It is also the principal channel by which the nitrogen resulting from the decay of the azotised tissues, and from the oxidation of the nitrogenous constituents of food, is carried off.

The following table, showing the average composition of healthy human urine (sp. gr. 1·020), is from Miller's *Chemistry*:—

				In 100 parts of the solid matter.
Water		. . . . . .	956·80	
Solid matters, 43·2	Organic matters, 29·79	Urea . . .	14·24	33·00
		Uric acid . .	0·37	0·86
		Alcoholic extract	12·54	29·03
		Watery extract .	2·51	5·80
		Vesical mucus .	0·16	0·37
	Fixed salts, 13·35	Chloride of sodium	7·22	16·73
		Phosphoric acid	2·12	4·91
		Sulphuric acid	1·70	3·94
		Lime . .	0·22	0·49
		Magnesia . .	0·12	0·28
		Potash . .	1·94	4·47
		Soda . . .	0·06	0·12
			1000·00	100·00

Dr. Golding Bird obtained the following results, in examining 1,000 parts of the urine of a healthy person after ten hours' fasting (*urina sanguinis*), and the urine after dinner in the evening (*urina cibi*):

Analysis of Urine	After fasting	After eating
Specific gravity . .	1·016	1·030
Water	962·72	930·10
Solids	37·28	69·90
Urea	14·30	24·40
Uric acid	0·23	1·33
Fixed salts, chiefly chlorides, sulphates, and phosphates .	5·10	9·90
Organic matter, creatin, creatinine, colouring matter, and volatile salts . . .	17·90	34·27

The above details will give an insight into the composition of healthy urine. In many febrile affections, and in gouty and rheumatic habits, the relative proportion of uric acid is often greatly increased. In Bright's disease, albumen only, traces of which are usually found, sometimes exists in such quantity as to be coagulated by heat and precipitable by nitric acid. Some other substances which occasionally make their appearance are elsewhere mentioned.

Urea abounds in the urine of many carnivorous animals, as in the lion or tiger, and is accompanied by mere traces of uric acid; carnivorous birds excrete little urea, but much uric acid, which abounds also in the excretions of serpents. It appears that in animals which drink freely, the effete nitrogen of the system chiefly passes off in the form of urea; but in birds and reptiles which drink little, and when the urinary excretion is more solid than liquid, it is excreted in uric acid. In graminivorous animals urea and hippuric acid are the leading proximate principles of the urine which contain nitrogen, and they are often accompanied by large quantities of the carbonates of lime and magnesia, while the phosphates are in very small proportion, and pass off chiefly by the bowels.

Urinary Calculi.—When the uric acid of the urine, which we have already stated to be one of its most insoluble constituents, is secreted in any extraordinary proportion, it is passed in a solid state, generally in minute red crystals, or *red sand*; and these not unfrequently agglutinate, so as to form small *calculi* from the size of a pin's head upwards. These, passing with more or less pain from the kidney along the ureter into the bladder, produce what is termed a *fit of gravel*; and if one or more of them remain in the bladder, it may there so increase in size as to become too large to be passed with the urine, giving rise to symptoms of *stone in the*

bladder. The increase of this nucleus will be more or less rapid, according to the state of the urine; but if the inordinate formation of uric acid continues, that substance will frequently be deposited upon it in successive layers, and it will sometimes thus attain a considerable size, and consist almost entirely of uric acid. But if the uric attack in the kidney is transient, the small uric calculus in the bladder usually becomes incrusted with a white deposit, composed of *ammonio-magnesian phosphate*, perhaps with more or less *phosphate of lime*, this mixture forming what has been termed the *fusible calculus*. This gives rise to a second and frequent species of urinary calculus, viz. that in which a uric nucleus is enveloped in the phosphates. The natural tendency of the urine is to deposit these phosphates upon any extraneous matter or nucleus which may chance to be in the bladder; but the rapidity with which it is deposited is very different in different individuals, and accordingly the increase in size of such a calculus is sometimes very slow, and sometimes extremely rapid; and as the violence of the symptoms generally depends (but not always) upon the size of the concretion, they will be subject to great consequent irregularity. It does occasionally happen that calculi are formed in the bladder independent of any morbid state of the urine itself, or of any uric nucleus sent down from the kidneys; but these cases are rare, and appear to depend upon the accumulation of sand and mucus in certain disordered states of the bladder, which is gradually indurated into a nucleus, and which then goes on to increase in the phosphates; so that, on cutting such a calculus through the centre, we do not, as in the majority of cases, observe a uric nucleus, but the whole concretion is white and more or less crystalline, and usually consists of little more than ammonio-magnesian phosphate. The terms *uric* and *phosphatic diathesis* have been applied to those states of the system in which uric acid and the phosphates are abnormally present, and are respectively treated by alkaline and acid remedies. This outline of the formation of calculi includes by far the greater number of cases; but it occasionally happens that not only the nucleus, but the bulk of the stone, is made up of *oxalate of lime*, a substance not found in healthy urine. When these calculi come direct from the kidney, they often are grey and smooth, somewhat resembling a hempseed; or, when more carefully examined, are found to be a congeries of little rounded particles; but when they have increased in the bladder, they are then generally rough and brown on the exterior, whence they have acquired the name of *mulberry calculi*. Another, and more rare substance, which forms gravel and calculi, is the *cystin* or *cystic oxide* ($C_6H_6O_4S_2N$). It is a yellowish substance, translucent, somewhat crystalline, and exhales a peculiar fetid odour. When heated, it is remarkable for the large quantity of sulphur which it contains, amounting to about 25 per cent. Though insoluble in water, it dissolves in dilute acids and alkalies. Another very rare constituent of urinary calculi is *xanthin* or *xanthic oxide* ($C_{10}H_4O_4N_4$). The concretions containing it are pale brown and lamellar. Again, in some very rare cases small concretions of *carbonate of lime* have been voided, most probably originating in the prostate gland. Lastly, minute grains of *silica* are said to have been detected in the urine, and this substance has also been found in calculi; but it is rare, and in small quantity. Another rare form of calculus is also known, called the *uric oxide*. In concluding this sketch of the composition of the urine and urinary calculi, we cannot too strongly insist upon the importance of attending to the early symptoms of the disease, and to its first announcement, which *generally* consists in habitual turbidness and deposits in the urine. All persons are subject to occasional appearances of this kind; but when they are *constant*, they ought to be considered as alarming indications of further mischief. These, in their early stages, are almost always curable, either by diet, medicine, or both; but when once a stone has formed in the kidney or bladder, all hope of its removal, except by an operation (and even that is not admissible in the case of kidney calculi), is vain, nothing having been yet discovered to which the term *solvent* is properly applicable. The removal of the stone from the bladder is effected by operation in two ways: either by an incision into the bladder, and the removal of the stone by a forceps—this constitutes *lithotomy*; or by *lithotrity*, in which certain instruments are introduced by the urethra, so as to grasp the stone, and enable the operator to reduce it to fragments sufficiently small to allow of being voided by the usual passage. Of later years microscopic analysis has been very successfully applied to the detection of morbid conditions of the urine.

Urn (Lat. urna). In Mosses, the hollow vessel in which the spores are lodged.

Urn, Cinerary. A species of vase used to receive and preserve the ashes of the dead. Sir T. Brown's celebrated work, *Hydriotaphia, or Urn Burial*, contains a strange collection of learned fragments and philosophical reflections on this subject. Numerous descriptions of cinerary urns, both Roman and British, discovered at different periods in this country, will be found in the *Archæologia*.

Urocerata (Gr. οὐρά, *a tail*, and κέρας, *a horn*). The name of a tribe of *Terebrantia*, or boring Hymenopterous insects, in which the *terebra* or borer of the females is sometimes very long and prominent, and composed of three filamentary processes, sometimes capillary, and coiled in a spiral form in the interior of the abdomen.

Urodeles (Gr. οὐρά, and δῆλος, *manifest*). The name of that tribe of Caducibranchiate Batrachian reptiles which preserve the tail through all the stages of their existence.

Uropterans (Gr. οὐρά, and πτερόν, *a wing*). The name of a family of Amphipodous Crustaceans, including those in which the tail is

terminated by enlarged appendages in the shape of fins.

Uropygium (Gr. οὐροπύγιον). The base of the tail in mammals and birds.

Uroscopy. The judgment of diseases founded upon an inspection of the urine.

Ursa Major (Lat.). The Great Bear; one of the forty-eight constellations of Ptolemy, in the northern hemisphere, and near the pole. It is often mentioned in the most ancient histories, sacred and profane, under the various denominations of Arctos, Boötes, Helix, Callisto, Megisto, the Waggon, the Plough. It contains seven very conspicuous stars, called *septentriones*; whence *septentrio*, the north. [Rishis, the Seven.]

Ursa Minor (Lat.). The Lesser Bear; also one of the forty-eight constellations of Ptolemy. It was called by the Greeks *Cynosura*; i.e. the *Dog's Tail*. The pole star is in this constellation.

Ursulines. In Ecclesiastical History, an order of nuns, of which the origin is ascribed to Angela da Brescia, about 1537; but which derived its name from St. Ursula (a lady of the family of Benincasa at Naples). The Ursulines were bound to perform charitable offices to the sick, poor, and penitent. They were erected into an order by Gregory XIII. in 1577, at the solicitation of St. Charles Borromeo. They take, in addition to the three ordinary vows, a fourth—to devote themselves to education. (Waddington, *History of the Church*, p. 401.)

Ursus (Lat. *a bear*). A genus of plantigrade Carnivora in the system of Cuvier, restricted to those species which have three large tuberculate molars on each side of both jaws, the anterior lower and the posterior upper one being the largest. They are preceded by a tooth a little more trenchant, representing the carnassial tooth, and by a variable number of small premolars. In accordance with this dentition, the bears are omnivorous or frugivorous. They are heavy, stout-bodied animals, with thick limbs, and a very short tail: the cartilage of the nose is movable, and sometimes very long, as in the labiated bear, commonly called the *ursine sloth*. The bears of the northern regions pass the winter in a state of somnolency in dens or other hiding-places, and it is in these retreats that the female brings forth her young. The species best known are the common brown bear (*Ursus arctos*), the black bear (*Ursus americanus*), the grisly bear (*Ursus ferox*), the polar bear (*Ursus maritimus*), the *Ursus labiatus*, *Ursus thibetanus*, *Ursus malayanus*, and *Ursus syriacus*.

Urtica (Lat. *a nettle*). This genus gives its name to the order *Urticaceæ*, and consists for the most part of erect herbaceous plants, covered with stinging hairs, and commonly called Nettles. The species are numerous, and some of them very widely distributed. The stinging property is met with to a slight extent in our English nettles; but some of the Indian species are particularly powerful in this respect, especially *U. crenulata* and *U. stimulans*. Both these, however, are exceeded by *U. urentissima*, a native of Timor, where it is called by the natives the Devil's-leaf; its effects are so violent as to last for twelve months, and even to produce death. The sting of the Nettle has a bulbous base, which serves as a reservoir for the acrid fluid.

The young tops of the common Nettle (*U. dioica*) are eaten as a vegetable, and may easily be forced for that purpose, when nothing better is to be had; but they are gritty, from the abundance of crystalloid matter contained in the cells of the epidermis. *U. dioica* is, moreover, a very ancient textile plant, its inner bark affording a tough fibre used by the inhabitants in many parts of Europe for making cordage, fishing-lines, coarse cloth, &c. A yellow colouring matter, employed in domestic dyeing, is obtained by boiling the roots with alum; and a decoction of the plant, mixed with salt, coagulates milk.

Some of the species of Nettles possess medicinal properties. Thus, *U. baccifera* is used in the West Indies as an aperient; the root of *U. pilulifera* is astringent and diuretic; nettle-tea, an infusion of the leaves of *U. dioica*, is much used by the peasantry in this country to purify the blood; and the tubers of *U. tuberosa* are eaten, raw, boiled, or roasted, by the natives of India.

Urticaceæ (Urtica, one of the genera). A large natural order of diclinous Exogens, with apetalous flowers, small flat stipules, limpid juice, solitary erect ovules, straight albuminous embryos, and a superior radicle. The stinging properties of the common Nettle are participated in by many others whose acridity is intense, and a tough fibre occurs in many others of the order. They consist of trees, shrubs, or herbs from almost every part of the globe. Taken in an extended sense, the order includes *Artocarpaceæ*, with pendulous ovules and no albumen to the seed; and *Moraceæ*, with pendulous ovules and albuminous seeds; but it is more frequently confined to the *Urticeæ* proper, which have erect ovules and albuminous seeds. The order thus restricted still comprises about forty genera. The species of *Böhmeria* and *Girardinia*, formerly included in *Urtica*, yield valuable fibres. [Böhmeria.]

Urticaria. [Nettle Rash.]

Urvasî. In Hindu Mythology, the story of Urvasî and Purûravas expresses the correlation of the Dawn and the Sun (as in the tales of Daphne, Coronis, Callisto, Augê, and Procris), and the identity of the morning dawn and evening twilight (as in the legends of Iolê, Iocastê, and Œnônê). Even in the Veda, the original meaning of these names has almost faded away; but Professor Max Müller accepts the common Indian explanation which connects the name with *uru*, wide (Gr. εὐρύ), and a root *as*, to pervade, and compares this name *uruasî* with another epithet of the dawn, *urûkî*, the far-going. Thus the name attaches itself to that large class which includes Eurydike, Euryanassa, Eurytos, Eurynome, Eurymedusa.

&c. &c. Again, Vasishtha, the superlative of *vasu*, bright, is, like Phœbus and Lykios [LYCAON], a name for the sun, and Vasishtha is said to owe his birth to Urvasî. In the Hindu story Urvasî falls in love with Purûravas, as Selene is charmed with Endymion; but the name Purûravas corresponds to that of POLYDEUKES, while the hero speaks of himself also as Vasishtha. He is also the son of Idâ, a name sometimes applied to Agni (Ignis), the fire, and reappearing perhaps in that of Idas father of Cleopatra, as well as in the Trojan Ida. The compact between them was that Purûravas was never to appear before Urvasî unclothed; but the GANDHARVAS came and stole two lambs belonging to her, and when Purûravas rose from his couch to rescue them, a flash of lightning revealed his naked form, and, like EURYDIKE from ORPHEUS, Urvasî vanished away. But once again on the banks of a lake full of lotus-flowers, Urvasî showed herself for an instant to her lover, who was seeking her in deep grief. On being addressed by him she replies, 'I am gone like the first of the dawns: I am hard to be caught, like the wind;' but before she leaves him, she bade him come to her on the last night of the year. [YULE.] On that day she told him that the Gandharvas would grant him one wish, and bade him say to them, 'Let me be one of you.' So Purûravas became one of the Gandharvas.

This tale, reproduced, in part, in that of Orpheus, reappears likewise in that of Procris, who is slain unwittingly by the spear of Kephalos, the ray of the unveiled sun. [MYRMIDONS.] It has incidents also in common with the story of Eros and PSYCHE, and all the other tales with which that myth is closely connected. [VENUS.]

Usance (Fr. from Lat. usus, *use*). In Commercial Law. A foreign bill is often drawn at one, two, or more *usances*, meaning thereby certain periods of time which it is the usage of the countries between which the bills are drawn to allow for payment thereof. Thus, the *usance* between London and Paris is one calendar month; a bill drawn here at one *usance*, on January 2, is payable there on February 5, allowing three days of grace.

Use (Lat. usus). In Law, this word, in its original sense, signified the equitable right which one person had to take the rents and profits of land of which the legal ownership was in another. It was very nearly the same as the trust of the present day, and was created in the following manner: The owner of land conveyed it by feoffment to some friend, on the understanding that the feoffee should hold it for the sole use and benefit of the feoffor, or such persons as he might nominate. In this way the seisin or legal property of the land became vested in the feoffee to uses as trustee; while the feoffor, or other person nominated by him, who was called the *cestui que use*, had the substantial use and enjoyment of it. The simplicity of the common law, however, recognised but one person in connection with the soil, viz. its real owner, and repudiated the idea of any use as separated from the seisin; so that if the trustee, abusing the confidence placed in him, refused to let cestui que use take the rents and profits, there was no redress for the grievance. But the Court of Chancery, as a court of equity, considered the agreement entered into by the trustee as binding on his conscience; and after calling on him by writ of subpœna to appear and make a disclosure on oath of the particulars of his trust, compelled him to perform it.

The system of uses was transplanted from the civil law, and introduced into this country about the time of Edward III. by the ecclesiastics, who procured conveyances to be made, not directly to themselves, but to lay persons as trustees for them, in order to evade the Statutes of Mortmain. Once known, it was generally adopted; and though crushed in its infancy, so far as regarded religious houses, it continued to flourish without disturbance in other respects, and was found admirably adapted to the wants and convenience of the people at large in softening the rigours of feudal tenure, and facilitating the alienation and settlement of property.

The laws and policy of feudal tenure required the vassal to render certain fruits and services to his lord; and if these were not duly rendered, or any act were done in derogation of the lord's title, the estate was forfeited. The tenancy of the freehold could not be interrupted or suspended for an instant; and to every transfer of it actual and public delivery of possession was absolutely indispensable; so that the lord might always have some person to perform the services due to him, and always know with certainty who that person was. The lord was entitled to sell his ward in marriage, to take the profits of the land during the wardship, and on the descent or alienation of the land heavy fines were payable to him. The tenant had no power of directing the destination of the land by will; such a mode of disposition would at once have been wanting in notoriety, and have deprived the lord of his fruits upon a descent.

When, however, the equitable interest in land, as distinguished from the legal property in it, became recognised and enforced in the Court of Chancery, the principal hardships of tenure were easily avoided. A conveyed land to B to A's own use; the terms upon which B took the land were said, in equity, to affect his conscience, and to impose upon him a moral obligation to fulfil them honestly. But it was in equity only that A had any claim: there he might call upon B to allow him to take the profits of the land, and to make such conveyances of it as he might from time to time direct. At law A had no control over or connection with the land any longer remaining to him. His use, therefore, altogether evaded the grasp of tenure, which rested entirely upon the common law. It was held of no one; it was the

creature of his own declaration, operating upon the conscience of the person in whom he confided. It might be transferred at any time without any public solemnities by a secret declaration. At law A could not carve out for himself a portion of the whole fee, and limit the residue of it to others, without first of all going through all the formalities of a conveyance to B, and then taking back a reconveyance, with the same formalities, of that portion of the fee which he might wish to retain to himself. Husband and wife being one person in law, he could not carve out a portion for her without conveying to B, in order that B might afterwards convey to her. He could not convey the fee, or any portion of it, to B, so that it should, on the happening of any named event, or the expiration of any named period, shift either wholly or in part from him to any other person. He could not even convey to B at all without giving him immediate possession: a conveyance to him in futuro, as from Christmas next, would have been altogether void. He might, however, resorting to equity, and making a declaration of the uses to which he wished his property to be applied, effect all these and innumerable other arrangements by a single stroke of the pen, or a mere breath. The use, emancipated from the common law, had such a suppleness and pliability as almost to accommodate itself to his very whims. He might dispose of it by will, or it would descend to his heirs in the course of the common law; but no fine was payable upon its descent. It was not liable either to dower or to curtesy; it was not extendible for debts, nor forfeited for treason. Lord Bacon accordingly complains, that it 'deceived many of their just and reasonable rights. A man that had cause to sue for land knew not against whom to bring his action, or who was the owner of it. The wife was defrauded of her thirds; the husband of his curtesy; the lord of his wardship, relief, heriot, and escheat; the creditor of his extent for debt; and the poor tenant of his lease.

To remedy these and other inconveniences, the statute 27 Henry VIII. c. 10 was passed, usually called the Statute of Uses; which enacts, that when any person shall be seised of lands to the use, confidence, or trust of any person, he shall thenceforth be seised and possessed of the land of and in the like estate as he had in the use, trust, or confidence. The statute thus executed the use, as it is called, by transferring it into possession, and doing away with the distinction between the beneficial interest and legal property in land. Whoever had the use had now also the legal estate. Thus the use was not abolished, according to the probable intention of the legislature, but merely annexed to and incorporated with the legal estate; to which, therefore, it now superadded all the convenient ductility of its own nature. It had no longer a merely precarious existence in equity, but a firm locus standi in courts of law. It was shorn, indeed, of many of its old privileges, such as exemption from dower, curtesy, and forfeiture; but for this loss there was soon contrived a remedy. The judges, in their narrow construction of the statute, decided that its provisions did not extend to *a use limited upon a use*, as their phrase was. Accordingly, on a feoffment to A and his heirs, to the use of B and his heirs, to the use of (or in trust for) C and his heirs, they held that the statute clothed the first use with the legal ownership, and that the second was a nullity. But as it was quite clear that C, and not B, was the person intended to enjoy the estate, this verbal pedantry of the common law judges drove C into the Court of Chancery for relief, where he was immediately received as the substantial cestui que use; and the use which the statute had been in law held not to execute was considered a valid *trust* in equity. Thus by limiting two uses successively instead of one only before the statute—by making, in fact, the conveyance only three words longer than had been customary, the equitable interest and the legal estate were again disunited, and the use under its new name of *trust* was as popular and available as ever. In this manner the destructive qualities of the statute are virtually repealed, while its creative qualities are to this day in full operation; and the legislature, instead of paralysing the use, has only given new form and flexibility to the legal estate. [TRUST.]

Useful Knowledge, Society for the Diffusion of. [SOCIETY.]

Usher (Fr. huissier). An officer who has the care of the door of a court or hall, &c. In the court of England, he is an officer of considerable rank, whose business it is to introduce foreign ambassadors or other high strangers to the sovereign.

Usnin or **Usnic Acid.** A substance extracted from different lichens of the genus *Usnea.* It forms yellow crystals, which with great difficulty are fused like a resin. It has slightly acid characters, and forms crystallisable compounds with the alkalies: hence it has been called *usnic acid.* Its ultimate composition is represented by the formula $C_{38}\,H_{18}\,O_{14}$.

Usquebaugh. A strong compound cordial, made in greatest perfection at Drogheda in Ireland. Brandy or other spirits, raisins, cinnamon, cloves, and various other spices are its ingredients. The first part of the word, which has been corrupted into *whisky*, is akin to the Latin aqua, the Greek ACHELOUS, ACHERON, and the many collateral forms exhibited in the names of rivers, as Esk, Usk, Exe, Ax, Axius, Oxus, Ouse, Isis, &c.

Ustrinum (Lat. from uro, *I burn*). In Roman Antiquities, a public burning-place, enclosed by walls, in which bodies, mostly of the poorer sort of people, were consumed. In the *Archæologia* (vol. xxvi.) will be found a detailed account of the site of an ustrinum discovered in Cambridgeshire.

Ustulation (Lat. ustulo, *to burn*). A term of old Pharmacy, implying the gradual desiccation and torrefaction of substances.

Usucaption (Lat. usucapio). In Civil Law, the acquisition of property in anything by possession and enjoyment for a certain term of years; commonly considered as synonymous with *prescription*, although some have restrained the use of the former term to movables only.

Usufruct (Lat. ususfructus). In the Civil Law, this term is defined to be the right of enjoying indefinitely something belonging to another without diminishing its substance. *Usufruct* differs from *use*; because he who has the use of a thing can only enjoy it personally, whereas the right of him who has the usufruct is alienable, and may be granted, sold, or hired to another. Usufruct may be constituted in four ways: by contract, by will, by judgment of a court (as where the judge, in effecting a division of common property, may, under certain circumstances, instead of dividing the inheritance, allot the usufruct to one, and the thing to another), and by operation of law. Usufruct is, properly speaking, confined to things real, and to incorporeal rights (whether they would be termed *real* or *personal*, according to the division of our law), such as debts; but a sort of usufruct (quasi usufruct) may exist in things liable to be consumed by use. The division between the fruit (which belongs to the usufructuary) and the thing itself (which belongs to the proprietor) affords room for a great variety of legal distinctions. Usufruct may be extinguished in several ways: by the death, natural or civil, of the usufructuary; by loss; by prescription, the right being extinguished if disused for a certain period; by forfeiture, where the usufructuary abuses his right; by expiration of time, if the usufruct have been granted for a term; and by the union of the usufruct with the property in the same hands.

Usury (Lat. usura, *the use of a thing*: hence profit arising from this use). The taking of interest for money. The Jews were forbidden by the law of Moses to exact interest from one another. By the old Roman law of the twelve tables, the rate of interest allowed as legitimate was the usura centesima, which was strictly 1 per cent. a month; and has been supposed by some to have amounted to 12, by others to 10 per cent. in the year. Interest was also computed in the following manner: Usura unciaria, being the lowest term, 1 per cent., or one-twelfth of the usura centesima; usura semis, or semis, half the centesima (6 per cent.); bes, quadrans, quincunx, &c., two third parts, a quarter, a fifth of the centesima (8, 3, 2 per cent.). The Roman laws against excessive usury were frequently renewed, and constantly evaded; but the same principle, additionally sanctioned by mistaken religious opinions, pervaded the laws of all countries in which the civil jurisprudence prevailed. The amount of legal interest has been fixed by various statutes in England. In the reign of Henry VIII. 10 per cent. was allowed; by 21 James I., 8 per cent.; by 12 Ch. II., 6 per cent.; by 12 Anne, 5 per cent.

Subsequently to the passing of the latter Act, the usury laws were relaxed by several statutes, and they were ultimately repealed in 1854. Any rate of interest, therefore, however high, may now be legally stipulated for, but 5 per cent. remains the legal interest recoverable on all contracts, unless otherwise specified.

One of the earliest and most consistent among the fallacies which have ever occupied men's minds, and not only the minds of the general public, but those of the most subtle thinkers, is that which has contended that the interest of money was unlawful, immoral, or inexpedient. It is clearly the duty of society to protect creditors against debtors, but from time to time it has been considered just to relieve debtors against creditors, when the obligations of the former have arisen from usury taken for the loan of money. Thus the legislation of Solon relieved the Athenian mortgagors [SEISACHTHEIA]; and during many years of the history of republican Rome, the regulation of loans, the limitation of the rate of interest, and the relief of insolvent debtors, formed a perpetual topic of agitation, and finally of legislation. In this country, and in most European countries, the administration has busied itself from time to time in fixing rates of interest, and in denouncing or forbidding usurious bargains. It is hardly necessary to say that this legislation has been vain, and that while the most stringent laws were in force, high rates of interest on loans were common, the law being incompetent to provide such precautions as should obviate all evasions of the statute. (For further remarks on the distinction between ancient and modern debts generally, see Grote, *Hist. of Greece*, part ii. ch. xi.)

The usury laws now repealed were attacked with great force and cogency by Bentham. [INTEREST.]

Ut. In Music, the French name of the first of the musical syllables referring to the note which we call C. The Italians, for the sake of softening the sound, use the syllable *do* instead of *ut* in the modern solfeggi.

Uterine (Lat. uterinus). In Anatomy, that which appertains to the womb, as the uterine arteries, veins, nerves, and the uterine portions of the placenta or cotyledons.

UTERINE. In the Civil Law, a uterine brother or sister is one issued from the same mother.

Uterus (Lat.). The womb, or the muscular and vascular part of the efferent canal or tract in the female viviparous or ovo-viviparous animal, in which the fœtus is developed. In the human subject and in quadrumana it is single; in many quadrupeds it is bifid; in some, it is completely divided into two symmetrical uteri.

Uti Possidetis (Lat. *as you hold*). In Politics, a treaty, which leaves belligerent parties mutually in possession of what they have acquired by their arms during the war, is said

to be based on the principle of *uti possidetis* (as you possess).

Utilitarians (Lat. utilitas, *usefulness*). A name much in use a few years ago to designate a particular sect of modern politicians; those viz. who profess to try the excellence of modes of government and usages simply by their utility. The celebrated Jeremy Bentham, regarded as the founder of this sect, introduced into the critical department of politics a closer logic than had been commonly applied to it; and aimed at applying his famous principle, 'the greatest happiness of the greatest number,' as an immediate test by which to affirm or deny the value of institutions. It is evident that all political sects, both of writers and statesmen, profess ultimately the same object. The real characteristic of the Utilitarians consisted in the peculiar sense in which they understood it, the term *utility* being restricted to that which is useful for the material and economical well-being of the multitude. Their tenets were attacked by Lord Macaulay in two celebrated articles in the *Edin. Review* (vols. xlix. and l.). Mill's *Essay on Government*, and Austin *On Jurisprudence*, may be referred to as containing the most intelligible summaries of them.

Utopia. A term coined by Sir T. More (from Gr. οὐ, neg. and τόπος, *a place*), and applied in his celebrated work called *Utopia* to an imaginary island, which he describes as having been discovered by a companion of Amerigo Vespucci, and as enjoying the utmost perfection in laws, politics, &c., in contradistinction to the defects of governments then existing. (Hallam, *Literary History*, part i. ch. iv. 34.) The work was first printed in 1516, but Froben's edition, of 1518, is more correct. The word *Utopia* has now passed into all the languages of Europe, to signify a state of ideal perfection; and *Utopian* is used synonymously with *fanciful* or *chimerical*.

Utr. An Eastern name for the essential oil or attar of roses.

Utraquists (Lat. uterque, *both*). In Ecclesiastical History, a name given to the followers of John Huss as insisting on Communion in both kinds. This stipulation formed one of the four articles drawn up at Prague, A.D. 1422. (Milman, *Latin Christianity*, bk. xiii. ch. xi.)

Utriculus (Lat. dim. of uter, *a leathern bag*). In Anatomy, this term is applied to the upper and larger of the two divisions of the vestibular portion of the membranous labyrinth of the internal organ of hearing.

Utriculus. A term in Botany applied to a one-celled, one or few seeded, superior membranous fruit, frequently dehiscing by a transverse suture, as in *Chenopodium*. It is also used to indicate a fruit with a thin skin and a single seed. Sometimes this word is employed to express a separate cell of the cellular tissue of a plant, which is usually a little vegetable bladder.

Uva Ursi (Lat.). The *Arctostaphylos uva ursi*, or *Bear's berry*, a small shrub, the leaves of which have a highly astringent and sweetish taste. Their decoction or infusion is occasionally used in medicine, especially in certain disorders of the kidney and bladder.

Uvaria (Lat. uva, *a grape*). A genus of *Anonaceæ*, containing numerous species, all climbing plants, covered with star-shaped hairs, and occurring in the tropical and subtropical districts of the Old World, from Western Africa to the Philippine Islands. The roots of *U. Narum* are fragrant and aromatic, and are used medicinally in India, in fevers and liver complaints. Bruised in salt water, they are employed as an application in certain skin diseases; by distillation they yield a fragrant greenish oil. The bark of *U. tripetaloidea* yields by incision a fragrant gum. *U. triloba* is said to contain a powerful acid; its leaves are used as an application to boils and abscesses, while its seeds are emetic. *U. febrifuga* is so called from the febrifugal properties ascribed to the flowers by the Indians on the Orinoco.

Uvic Acid (Lat. uva). A synonym of the *racemic* or *paratartaric acid*, an acid isomeric with the tartaric, but differing from it in certain respects, more especially in its relations to polarised light. [Tartaric Acid.]

Uvula (Lat. uva). A small fleshy protuberance attached to the soft palate, and hanging over the base of the tongue. It consists of the common integuments of the mouth, and a small vermicular muscle (*palato-staphilinus*) by the contraction of which the uvula is elevated. In some cases of enlarged or relaxed uvula, which will not yield to local or other remedies, it becomes necessary to amputate a part of it, in consequence of the tickling cough and retching which it induces.

Uwarowite. A lime-chrome Garnet of an emerald-green colour, found at Kyschtimsk and Bissersk in the Ural; and named after Uwarow, president of the Imperial Academy of St. Petersburg.

V

V. The twenty-second letter of the English alphabet. It is vocal, the corresponding aspirate being F. In many Greek words it is represented by the Digamma. As a Roman numeral, V stands for 5. With a dash over it, $\bar{V}$, in old books, it denotes 5,000.

Vacation. In Legal language, the period during which juridical proceedings are intermitted: in England, the periods between the four terms of the year [Terms] are so called. But the *long vacation*, from August 10 to October 24, at Common Law, and October 28

in Chancery, implies a more general cessation of all but urgent business.

Vaccination. [Cow-pox.]

Vacciniaceæ (Vaccinium, one of the genera). A natural order of epigynous Exogens closely allied to *Ericaceæ* in their stamens being free from the corolla, and in the peculiar form of their anthers as well as in most other characters, but separated by almost all botanists on account of their constantly inferior ovary and fruit. They consist of much-branched shrubs or small trees, often evergreen. The species are numerous in the temperate and colder parts of the world, especially in swampy or subalpine countries, as well as in high mountain chains within the tropics. They were formerly combined with the Ericaceous order, from which, however, they differ, not only in their inferior ovary, but also in their succulent fruit. The berries of many are eaten, under the names of Cranberry, Bilberry, Whortleberry, &c.

Vaccinic Acid. A peculiar volatile acid which occasionally replaces the butyric and caproic acid in butter.

Vaccinium (Lat.). A genus of heath-like shrubs, dispersed through a very wide area in both the Old and New World, and generally in mountainous districts or wet heathy places. Three species are natives of Great Britain, the most frequent being *V. Myrtillus*, the Whortleberry or Bilberry, an erect little shrub, common on our heathy wastes, whose fruit is much esteemed for preserves, syrups, &c.

Vachellia. A name under which it was proposed to separate *Acacia Farnesiana* from the other species of that genus. It is now usually retained as a section of that extensive family, and includes the gum arabic tree (*Acacia arabica*) and other gum-producing species. The flowers of *Acacia Farnesiana* afford the Cassie flowers of the perfumers, who extract their fine violet-like odour by macerating them in purified fat or the finest olive oil, and use it in the preparation of various bouquets, or for mixing with violet perfumes to increase their strength. Originally it appears to have been confined to the tropics of the western hemisphere, but it is now common in nearly all tropical countries, and also in many parts of the south of Europe, where it was introduced early in the seventeenth century. Large quantities of gum, resembling inferior gum arabic, exude from its trunk and branches.

Vacuna (Lat.). In Mythology, a Sabine deity, who is thought by some to be the same as the Latin *Victoria*. (Ov. *Fast.* vi. 307.)

Vacuum (Lat. vacuus, *empty*). In Physics, this term denotes a portion of space void of matter. The possibility of the existence of a perfect vacuum has been a favourite subject of dispute with the schoolmen and metaphysicians. [Space, Number, and Time; Space, Physical.] Its existence was maintained by the Pythagoreans, Epicureans, and Atomists; and denied by the Peripatetics, who ascribed the rise of water in a sucking-pump, and some other phenomena of the same kind produced by atmospheric pressure, to nature's abhorrence of a vacuum. Descartes made the essence of matter to consist in extension, and therefore denied the possibility of a vacuum; for if extension be the essence of matter, wherever extension is there matter must be. Those, again, who suppose all material bodies to be formed of the agglomeration of elementary particles, are compelled, by the phenomena of motion, to admit at least the existence of that which the schoolmen called *vacuum interspersum*, or of intervals devoid of all matter among the interstices or pores of bodies; for if there were no interstices, all space would be full of matter, in which case no body could be moved out of its place, inasmuch as there would be no unoccupied place into which it could move. For the arguments on this subject, see Newton's *Optics*.

Until recently the most perfect vacuum that could be produced was the *Torricellian vacuum*, or the space above the mercury in the barometric tube. But in this sense vacuum merely signifies the exclusion of atmospheric air; for this space in the barometer may be filled with the vapour of mercury, or with some other medium infinitely more rare than air, and inappreciable to our senses. It is obvious, from the nature of the pneumatic machine, that the vacuum produced by an air-pump, or the *Boylean vacuum*, as it has been called, can never be perfect, as some air must always remain in the receiver, however long the exhausting process may be continued, but if the receiver be first filled with pure carbonic acid, a stick of caustic potash introduced, and then the receiver be exhausted as perfectly as possible, the stick of potash will gradually absorb the small residuum of carbonic acid, and a vacuum far exceeding the Torricellian will be produced after the lapse of a few hours. This is by far the most perfect vacuum that has yet been obtained; but the electric discharge sent through it still proclaims it to be imperfect.

The question of the abstract existence of a vacuum is not worth discussing; but there is another question of great interest with reference to physical astronomy connected with the subject—viz. whether the spaces in which the planets move are so far void of matter as to offer no resistance to their motions, or are occupied by a medium of sufficient density to impede their motions in the long run in a sensible degree. Recent observations appear to give some countenance to the supposition that this is actually the case. It has been observed that after the most careful allowance has been made for the attractions of the planets, and all other known causes of disturbance, on Encke's comet, the successive returns of that body to its perihelion are accomplished in periods which are constantly diminishing. [Comet.] Now, this is precisely the effect that would be produced if the body moved in a medium which offered

a small resistance to its motion; and as this is the only obvious mode of explaining the phenomenon, it has been generally adopted. Nevertheless, it is extremely difficult to reconcile the supposition of an existing medium with the astronomical fact, that, during the last 2,000 years of observation, it has produced on the motions of the large planets no effect which can be appreciated by the most delicate instruments. This fact, however, though it proves the extreme feebleness of the resistance, does not furnish an absolute proof that such a medium may not exist, and that its effects may not ultimately become sensible even on the densest planets. If it does exist, the consequence seems inevitable that all the planets and satellites, as well as the comets, must be ultimately precipitated into the sun.

Another argument against the existence of a vacuum is furnished by the undulatory theory of light. If this hypothesis be true, and it is rendered probable by numerous phenomena, a medium of great elasticity must pervade all the parts of space through which light penetrates. There could in this case be no vacuum; unless, indeed, the term be understood to denote merely the absence of ponderable matter. [LIGHT.]

Vade Mecum (Lat. *go with me*). A phrase commonly used to denote a portable book or manual, which anyone carries on his person.

Vade in Pace (Lat. *go in peace*). In monastic communities offences were sometimes punished by the dreadful infliction of starving the culprit to death in prison; and bones have occasionally been found among the ruins of convents of victims who appear to have perished in this manner. The punishment acquired this name from the words in which the sentence was pronounced. The use which Walter Scott has made of this custom in his poem of *Marmion* is well known. By Fleury (*Hist. Eccles.* vol. xx. p. 102) the *vade in pace* is described as perpetual solitary imprisonment.

Vagantes (Lat. part. of vagor, *I wander*). The name of a tribe of spiders (*Araneidæ*), comprehending those which watch their prey concealed in a web, but also frequently run with agility, and chase and seize their victims.

Vagina (Lat. *a sheath*). This term is applied by botanists to the leafstalk of those plants in which this part becomes thin and rolls round the stem, to which it then forms a sheath, as in grasses.

Vaginates (Lat. vagina). Sheathed Polypes. The name of an order of Polypes, comprehending those which are constantly surrounded by and attached to a calcareous or horny polypary.

Vagrancy (Lat. vagor, *I wander*). In English Law, a very miscellaneous class of offences against public police and order is comprehended under this title. Vagrants, under the present Act of Parliament in force on the subject (5 Geo. IV. c. 83, amended by 1 & 2 Vict. c. 38), are of three descriptions: 1. *Idle and disorderly persons*: including persons neglecting to maintain their families; paupers returning without certificate to parishes whence they have been legally removed; beggars, common prostitutes, pedlars without license, &c.; all of whom may be summarily convicted and committed to gaol for a month by any single justice, subject to an appeal to the sessions. 2. *Rogues and vagabonds*: including persons guilty of the former offences, who have been once already convicted of being idle and disorderly; fortune-tellers and other impostors; persons guilty of indecent exhibitions, procurers of charitable contributions under false pretences, playing at games of chance in public places, having in their possession housebreakers' implements, or offensive weapons, with intent to use them; reputed thieves frequenting public places to commit felony, and others; all of whom may be committed for three months. 3. *Incorrigible rogues*: viz. persons guilty of the last class of offences having been already convicted; persons breaking out of legal confinement, &c., who may be committed to the next sessions, and there sentenced to a year's imprisonment. Under these Acts, justices possess very extensive powers, such as to issue warrants to bring before them persons suspected of vagrancy, to search lodging houses reasonably suspected of harbouring vagrants, &c.

Vahea. A genus of *Apocynaceæ* yielding Caoutchouc. Much of the Indian-rubber consumed by our manufacturers is obtained from *Siphonia brasiliensis* and *Ficus elastica*; but the same substance is found in the milky juice of numerous plants belonging to the natural order *Apocynaceæ*: e. g. *Urceola*, *Cameraria*, *Collophora*, *Willughbeia*, and the present genus, although, with the exception of *Urceola*, it is not collected from them for commercial purposes. Two species of *Vahea*, viz. *V. madagascariensis*, the Voua-Héré of the natives, and *V. gummifera*—both large climbing shrubs or trees of Madagascar, are known to afford an abundance of caoutchouc, which will probably at no distant date form an article of export from that magnificent island.

Vair (perhaps from the Lat. varius, *diverse*). In Heraldry, one of the furs employed in blazonry. It is supposed to represent the skin of a small squirrel. It is always white and blue, unless otherwise specified in the blazon: as vair of *or* and azure, vair of ermine and gules, &c. *Vairy* is the pattern of vair with more than two colours. The *glass slipper* of Cinderella in the popular legend was probably a slipper of *vair*, altered by the storyteller into *verre*.

Vaisya. [CASTE.]

Valencianite. A variety of Adularia, found at the Valenciana Mine in Mexico.

Valentia. [ROMULUS.]

Valentine. February 14 is the day sacred to St. Valentine, a presbyter, who, according to the legend, was beheaded at Rome under Clau-

dius. Mr. Brand (*Popular Antiquities*, vol. i. p. 47) says that he cannot find in the life of the saint any circumstances likely to have given origin to the peculiar ceremonies of the day. It appears to have been a very old notion, however (for it is alluded to by Chaucer, as well as by Shakspeare in the *Two Gentlemen of Verona*), that on this day birds begin to couple. And the custom of 'choosing Valentines' is of great antiquity in this country. Lydgate mentions it (1746); Grose explains Valentine to mean 'the first woman seen by a man, or man by a woman,' on that day; but it does not appear where he picked up this explanation. There is also a curious French Valentine, composed by the poet Gower, in Wharton's *History of English Poetry* (Additions to vol. ii. p. 31).

It appears that the Reformers attacked this as well as other legendary customs of their time; and that the Romanists themselves invented devices for turning the day to profitable use. St. Francis de Sales introduced the practice of drawing lots for patron saints on it, by way of substitute. According to others, this latter practice was of much older date, and substituted for a pagan custom by which boys and girls drew each other's names on the 15th February (day of Februata Juno).

Valentinians. In Ecclesiastical History, a sect of the second century; so called from Valentinus, their founder. They were a branch of the GNOSTICS.

Valentinite. Native antimonic oxide, composed (when pure) of 84·3 per cent. antimony and 15·7 oxygen. It is found in tabular crystals at Przibram in Bohemia, and elsewhere, associated with other ores of antimony, of the decomposition of which it is a result. Named in honour of Basilius Valentinus.

Valerian. [VALERIANA.]

Valeriana. A genus of herbaceous plants, widely distributed over tropical and extra-tropical America, India, and Central Europe, and more sparingly in North America; found for the most part in mountainous districts. Many of the species are employed in medicine, on account of their peculiar stimulant and antispasmodic properties. The species now most used is *V. officinalis*, the Officinal Valerian, common in marshy and wet places in this country and Central Europe; the roots have a warm, aromatic, slightly bitter taste, and, when dry, a peculiar fetid odour, which seems to be especially agreeable to cats, who become, as it were, intoxicated with it. It is stated also that rat-catchers avail themselves of this root as a means of attracting their prey. This odour seems to be due to the presence of a peculiar acid called *valerianic acid*. What is known to chemists as *volatile oil of Valerian* seems not to exist naturally in the plant, but to be developed by the agency of water. Valerian is used in medicine as a powerful stimulant to the nervous system in hysteria, and even in epilepsy. On the Continent it has likewise been used as a febrifuge. *V. celtica* is supposed to be the Saliunca of ancient writers. Its perfume is so highly prized by Eastern nations, for the purpose of aromatising their baths, that the roots, collected by the Styrian peasants with no slight difficulty and labour, are exported by way of Trieste to Turkey and Egypt, whence they are distributed to India and Ethiopia.

Valerianaceæ (Valeriana, one of the genera). A natural order of epigynous Exogens consisting of annual or perennial herbs, inhabiting temperate climates. They are distinguished from the Dipsaceous order by their flowers not being in heads, by the want of albumen, and the absence of an involucel. The roots of *Valeriana officinalis* are aromatic and antispasmodic; and the young leaves of the species of *Valerianella* are eaten as salad, under the French name of *mâche*, or the English one of Lamb's Lettuce and Corn Salad.

Valerianic or Valeric Acid. This acid constitutes the leading ingredient of the volatile oil obtained by distilling valerian root with water. It may also be obtained from the root of *Angelica*; and it is contained in the bark of the *Viburnum Opulus*. Lastly, valerianic acid is artificially formed by the action of a mixture of quicklime and caustic potassa on the oil of potato spirit, the *fusel oil* of the Germans, the *hydrated oxide of amyl* of chemists, or by distilling fusel oil with a mixture of dilute sulphuric acid and bichromate of potash. The formula of this acid is $C_{10}H_9O_3 + HO$. It is an oily colourless liquid, boiling at 347° Fahr. (175° C.), smelling intensely of valerian; it has a sour, pungent, and nauseous taste, leaving a sense of sweetness and a white spot upon the tongue. Some of its combinations with bases have been used medicinally as nervine tonics.

Valesians. An ancient sect mentioned by Epiphanius, and supposed to have become known about A.D. 240; they are said to have adopted the practice of eunuchism.

Valet, Varlet. A term used originally to denote the sons of knights, and afterwards those of the nobility before they had attained the age of chivalry. The name is sometimes written *vasletus*, and seems to be derived from the same root with vassal; probably the Celtic gwâs. [VASSAL.] *Valet* in French, and *varlet* in English, degenerated in later times into the signification of *servant*.

Valhalla or **Walhalla.** In the Scandinavian Mythology, the place in which ODIN and the Æsirs dwell with the beautiful VALKYRIES and the heroes slain in battle. [THOR; TYR.]

Valkyries. In Scandinavian Mythology, maidens who dwell with the Æsir in Walhalla, and whose office it is, as corse-choosers, to conduct to the home of the gods the souls of heroes slain in battle. They were also called *Oska-mær*, or wish-maidens. [WISH.] Allowance being made for the influence of climate in the character of mythical systems, the valkyries

exhibit a close resemblance to the houris who are the reward of the faithful in the sensual paradise of Mohammed.

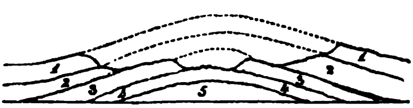
Valley (Lat. vallis). In Architecture, the internal angle formed by two inclined sides of a roof. It is supported by a rafter called the *valley rafter*, or *valley piece*; on which lies a board for the reception of the lead gutter, called the *valley board*.

Valley of Denudation. A valley formed by the direct action of water scooping out a passage for itself by its mere mechanical force. Such valleys are formed very rapidly in districts where the rocks are soft, as the water first eats away a passage for itself to a certain depth, and then widens this passage by undermining the banks which it has itself formed. When a wide gap has been formed, the water in different seasons deepens some particular channels, and afterwards these channels are widened, and so on until the result becomes very large. Sir C. Lyell relates as an example of the force of running water in denudation, that the river Simeto, the largest of the Sicilian streams, having had its course obstructed by lava, which was poured out in 1603, has since then eaten away through the lava a passage from 50 to 100 feet wide, and from 40 to 50 feet deep.

The action of marine currents at the bottom of the sea is also very great, and probably scoops out large hollows, which will be laid bare and become valleys at some future time, when the sea bottom shall have become dry ground.

Valleys of denudation are common in most countries, as the river channel of most streams is far larger than the space now occupied by the water.

Valley of Elevation. A valley formed in consequence of the lifting up of a considerable tract of country by an axis of elevation, followed, or accompanied by, a removal of the broken fragments on the axis by the action of water. The accompanying diagram will illustrate the phenomenon by a sectional view.



The beds 1 to 5 have been originally horizontal, but have undergone elevation, breaking the upper series. The elevation being supposed to be gradual, the removal of the broken rock of the various deposits would proceed continuously, leaving a succession of low ridges, in the direction of the axis; but instead of a hill in the central line of the axis, there would be a comparative depression or valley. It will be evident that a true valley is thus formed, although the lowest part of the valley is above the level occupied by the highest bed of the series before elevation commenced.

An important geological result follows this construction of the valley, as the beds 2 and 4 in the diagram will be seen to have the same position with respect to the sea level at the place where they crop out, although 4 is, geologically, much below.

It is possible that the lowest bed may, by the greater denudation of the upper ones, be nearly level with them.

Valleys (Lat. vallis). The phenomena of valleys possess great interest both to the physical geographer and the geologist. They are generally depressions in mountain districts, but the name is also applied to the channel by which any stream or river is conveyed along a plain country to the sea. In the former case they are not unfrequently characterised by some peculiar features, especially in the upper regions of high mountains, where the ice which partially occupies them often works its way into the plains below before melting. [GLACIERS.] In the latter case, the title *valley* belongs to large and wide plains, including not merely the present water current, but all that tract of alluvial matter which has in former times been deposited by the stream.

Besides the valleys traversed by rivers, and therefore lower at one end than at the other, there are many into which no water runs, while some, which are quite enclosed, allow no water that may enter them to escape, except by evaporation. In such valleys there are often lakes, some being SALT LAKES, the remains of sea water once contained in them.

Valleys have been formed in various ways. Some, called *valleys of erosion*, are due wholly to the rapid production of a channel by water rushing for a time as a torrent through a soft material. [VALLEYS OF DENUDATION; VALLEYS OF ELEVATION.]

Some mountain chains are remarkable for peculiar systems of valleys, and in some the position of the valleys is extremely elevated. This is especially the case in the knots of the ANDES.

A view has been put forth by some German geologists, and accepted by some of their English brethren, to the effect that all lake valleys have been scooped out by ice. This view may perhaps in many cases be extended to the larger river valleys.

There can be little doubt that the principal systems of valleys in mountain districts are due to the causes that have lifted the mountain chain itself, and that if the great valleys away from mountains are due partly to the rivers that still traverse them, they are more directly the result of the circumstances under which they have been elevated from the sea, and acted on during elevation.

Vallisneria (after Antonio Vallisneri, an Italian botanist). A genus of *Hydrocharidaceæ*, remarkable on account of the very curious manner in which the process of fertilisation is effected.

The best-known species, *V. spiralis*, found wild in many parts of Southern Europe, is a perennial herb, bearing a tuft of thin narrow green grass-like leaves. The two sexes are borne on separate plants. The male flowers

are extremely minute and sessile, but when mature they become detached, and rise to the surface of the water. The female flowers, on the other hand, are borne singly at the end of a very long slender spirally-twisted stalk, which uncoils more or less according to the depth of the water, so as to allow the flower to float upon the surface, where it expands and is fertilised by the floating pollen, after which the spiral stalk coils up again and conveys the flower to the bottom of the water.

The leaves of the *Vallisneria* form an exceedingly beautiful object under the microscope, the extreme tenuity and transparency of their cellular tissue allowing the observer to watch the movement of the fluid contents of the cells.

Some botanists have proposed to separate this and one or two allied genera from *Hydrocharidaceæ*, under the name of *Vallisneriaceæ*.

Vallum (Lat.). The name given to the wall or fortifications of a Roman camp. It was made, properly, of *valli* or stakes, and was thus a palisade run along the outer edge of the summit of the *agger* or rampart, raised by the earth excavated in order to form the *fossa* or trench, which ran round the agger. Each Roman soldier carried three or four of the valli, which were used in constructing the palisade.

Valonia. The cup of the acorn of *Quercus Ægilops*, imported from the Levant and the Morea. It is an important tanning material.

Valorem, Ad (Lat.). In Finance, a term employed to denote the market value of commodities imported and liable to a customs rate, whether it be that the duty is levied on articles which, being uniform in quality, vary from year to year in consequence of the demand being generally equal, but the supply uncertain, or which are different in quality though similar in character. Thus, for instance, the Ionian Islands levy an ad valorem duty on currants; the estimate being taken from the market value of the exported article. Such a value must vary with the largeness or smallness of the crop. On the other hand, the English customs acts levy an ad valorem duty on sugar; the import on the finer kinds being more than that on the coarser article, and most on that which is refined. When the article is not open to an obvious or easy test, some police arrangements are necessary, by which, as a rule, the object of the tax may be, in order to obviate fraud, put up to auction, or even sold at the price fixed on it by the importer.

As a rule, ad valorem duties are unsatisfactory on the ground of uncertainty. They have seldom been successful. On primâ facie grounds, it seems desirable, for instance, to tax high-priced wines at larger rates than cheaper goods; but it was felt that any attempt to introduce such a sliding scale of duties would be objectionable, and would be probably evaded. Even the sugar duties are the object of incessant attack. For the principle on which the government interprets average values of imports, see the *Commercial Dictionary*, art. 'Average in Imports.'

Value. In Political Economy, the estimate given of any commodity in contrast with all other commodities, and differing from price, which is the estimate given of any commodity by one value only, i.e. the value of the precious metals. There can be a general rise in prices, since the value of the single measure may fall: there cannot be a general rise in values, for values are relative and mutual. There may be, of course, a great rise or fall in the value of any one thing when it is scarce and in demand, or abundant and neglected. There cannot be a universal rise in values, or a universal fall in values, for if such a case could be for a moment conceived, no one would get any more in the first case, or any less in the second.

Economists distinguish value in use from value in exchange, the contrast between the two senses having been instituted by Adam Smith. (*Wealth of Nations*, book i.) By value in use, is understood the necessity of the object; by value in exchange, the demand for the object and its cost of production. Thus, the use of air and water is of the highest kind. But ordinarily there is no value in exchange assignable to these objects, unless indeed they are naturally limited and labour is expended on producing or supplying them. Thus, in a deep mine, or in a diving bell, air may possess a value in exchange, as in a populous city the supply of water always does. But food, however plentiful, is always possessed of value in exchange, because it is in demand, is limited in quantity, and must always be produced by labour.

Adam Smith is, however, not always consistent in his distinction, because he confounds use in the sense of moral utility or physical necessity, with the individual's use, as signified in demand. Thus, he says, a diamond has no value in use, but great value in exchange. It may have no use to wise persons, and if all persons were wise, it might have no value in exchange; but because it is demanded, it has a use, which the individual appreciates, and on the basis of which he admits its value in exchange. It is with value in exchange, or exchange value, only, that economists are concerned.

It will be seen, then, that the value of any given commodity or service is affected by two causes, one of which is temporary, viz. demand, and the other permanent, viz. the cost of production. In the long run, a particular value conforms to the last-named cause, but from time to time it is regulated by demand and supply, and may therefore rise and fall far above or far below the cost of production. From the fact that demand and labour determine values, some economists have insisted that the first of these causes is the true measure of value, while others maintain that value is determined by the second. Both are determining causes, but under different circumstances; and the statements, that labour is the cause of value, and demand is the cause of value, are, though apparently repugnant, two

phases of the same fact. [DEMAND; POLITICAL ECONOMY; PRICE; SUPPLY.]

Valvata (Lat. valvæ, *folding doors*). A genus of fresh-water snails or Gastropods; so called from the valve-like form of the operculum or lid which covers the aperture of the depressed spiral shell. Of this genus several species are British; as *Valvata obtusa*, common in the ditches at Battersea; *Valv. spirorbis*, *Valv. planorbis*, *Valv. minuta*, &c.

Valvate (Lat. valvæ). In Botany, a term applied to parts which are united by the margins only; as the sepals of rhamnads, or the valves of a capsule.

Valve (Lat. valva). A contrivance for opening and closing an orifice, either by spontaneous action or by external interference. Among the many varieties of valves employed in mechanics may be mentioned the *slide* or *sluice valve*, where the orifice is opened by drawing up a plate; the *flap valve*, which opens and shuts like a door; the *pot-lid valve*, where the orifice is closed by shutting down upon it a disc of metal; the *ball valve*, where the orifice is closed by a ball; and the *throttle valve*, where a disc of metal turning on a spindle passing through its edge may be made to stand across a pipe, and so close the opening. [STEAM ENGINE.]

Valves (Lat. valvæ). In Botany, the pieces into which the fruit of a plant naturally separates when it bursts. The name is also applied to similar parts in any other organ, as the anther.

Vambrace (Fr. avant-bras). The defence of plate armour worn on the forearm, in the suits of the fifteenth and sixteenth centuries. The covering of the upper arm was called the *rerebrace*, from the French arrière bras.

Vampire (Ger. vampyr). A blood-sucking spectre, the object of superstitious dread among various nations of Europe. The belief in vampires—i.e. in persons returning to the earth after death and burial, not as ghosts, but in actual corporeal substance, and sucking the blood of living men—appears to have prevailed in very ancient times. The Empusæ, Lamiæ, and Lemures were species of vampires. One of the most detailed stories of vampires is the tale which Goethe has made the foundation of his poem of the *Bride of Corinth*, in which the dead bride of a young man visits him at night, and withers him by her embrace. But in modern Europe, the populations among which vampire superstitions have prevailed appear to be of Slavonic descent. The word *vampire* is said by Adelung to be of Servian origin: and although the modern Greeks have also their vampires, yet the barbaric names by which they call them (Vroucolachas, Vuroulachas, Vardoulachas) seem rather to indicate a Slavonic, or perhaps Albanian source, for both the tradition and the word. In Crete they are called Katakhanàs, and firmly believed in. (Pashley's *Travels*.) About a century ago, there prevailed in several districts of Hungary an epidemic dread of vampires, which lasted some years, and gave birth to many extraordinary stories. It was believed that in several places those among the dead who belonged to the class of vampires arose nightly from their graves and sucked the blood of the living, who fell into consumptions and perished; that those who had died in this manner became infected with vampirism; and that the only way of exterminating the plague was by disinterring all the suspected vampires, and if it were discovered that they exhibited the tokens of their hideous character, burning them to ashes, or driving a stake through their middle. The attestations which these grotesquely fearful tales received are among the most singular instances of human credulity recorded in all the annals of superstition. [RATIONALISM; WITCHCRAFT.] They are, in many instances, related on the authority of the pastors and other most credible persons of villages and towns, who depose to having been themselves witnesses of the scenes beheld on opening the vampires' graves. Some, indeed, had actually seen the spectres themselves on their nightly excursions; but more generally the attestations are by persons present at the inspection of the dead bodies, when, if the subject was a true vampire, he was generally found of a florid and hale complexion; his hair, beard, and nails had grown; his mouth, hands, &c. were stained with fresh blood; his eyes open and brilliant. Sometimes, when the stake was driven through him, he was heard to utter cries like those of a living person. It was believed that the consumption produced by the sucking of the vampire could be cured by eating earth from his grave. The popular name of the vampire-bat (*Vespertilio spectrum*), a small animal of South America which sucks the blood of persons asleep, is derived from these imaginary monsters.

Vamplate (Fr. avant-plat). A large piece of plate armour of the sixteenth century, used in jousting to supply the place of arm and hand defence to the wearer, protecting him more effectually against his opponent's lance. Specimens may be seen in the armoury of the Tower of London, the Rotunda at Woolwich, &c. An excellent drawing and description of one is given in the *Archæological Journal*, vol. xxiii. 1866.

Van (Fr. avant, from Lat. ab, and ante). In Naval language, the foremost division of the line of battle, which is also the weather division when the fleet is on a wind.

Vanadinite. Native vanadiate of lead. A mineral found at the Susannah mine, at Wanlock Head, in Dumfriesshire, &c.; in small hexagonal prisms, but generally in implanted globules, or incrustations of a yellowish or reddish-brown colour. [VANADIUM.]

Vanadium. A metal discovered in 1830 by Professor Seftström of Fahlun, in iron prepared from the iron-ore of Taberg in Sweden. Vanadium has also been found in a lead-ore from Wanlock Head in Scotland, and in a

similar mineral from Zimapan in Mexico. Vanadium is a white brittle metal, very difficult of reduction; not oxidised by air or water; and insoluble in sulphuric, hydrochloric, and hydrofluoric acids, but soluble in nitric and nitro-hydrochloric acids, with which it yields solutions of a fine dark blue colour. It is not acted upon by boiling caustic potash, nor by the carbonated alkalies at a red heat. The peroxide of vanadium is of an orange colour, and very slightly soluble in water; it unites with the salifiable bases; with the alkalies its salts are soluble, with the other bases sparingly soluble. These salts are orange or yellow coloured; in these and other respects there is a close resemblance between vanadium and chromium. Peroxide of vanadium, or vanadic acid (VO_3), is distinguished from chromic acid by the action of deoxidising substances, which give a blue solution with vanadium, but a green one with chromium. When heated with borax in the reducing flame of the blow-pipe, both of the acids yield a green glass; but in the oxidising flame the bead becomes *yellow* if vanadium is present, but the green colour is permanent if produced by chromium. According to the experiments of Berzelius, the equivalent of vanadium is about 68; and the protoxide, the deutoxide, and the vanadic acid are composed respectively of 1 atom of vanadium, and 1, 2, and 3 of oxygen. It forms two chlorides, VCl_2 and VCl_3.

Vane (Dutch vaan). A contrivance for showing the direction of the wind. It consists usually of a thin slip of wood or metal, attached to a perpendicular axis, round which it moves freely; and is so shaped that it presents always the same extremity to the point of the horizon from which the wind blows.

Vanellus. A name applied by Bechstein to a subgenus of the Linnæan *Tringæ*, including the true lapwings, which are distinguished from the *Squatarolæ* of Cuvier by their more distinct, though small, hinder toe, and their partially scutellated tarsi.

Vanessa (or better *Phanessa*, from Phanês, a mystic divinity in the Orphic rites, also known as Eros, Ericapaios, and Protogonos). This term is applied to a genus of butterflies, in which the inferior palpi are contiguous in their whole length, terminating gradually in a point, and are much compressed.

Vang. A rope passing from the extremity or peak of a gaff to each of the ship's sides, for the purpose of steadying the spar.

Vanga. A name used to denote a species of birds which are by some combined with the crows, as part of the conirostral tribe. They are characterised by a large bill, greatly compressed throughout, the point of the upper mandible suddenly curved, and the under mandible bent upwards.

Vanguard (Fr. avant-garde). That part of an army which precedes the main body on the march, as a security against surprise.

Vanilla (Span.). The succulent fruit of *Vanilla planifolia*, and perhaps of other species. These are plants of the Orchidaceous order, climbing over trees in the tropical parts of America after the manner of ivy. The fragrance of the fruit is owing to the presence of benzoic acid, crystals of which form upon the pod if left undisturbed. It is an aromatic, employed in confectionery and the preparation of liqueurs, and in flavouring some kinds of chocolate, &c. This is, perhaps, the most important genus of the whole Orchidaceous family, and the only one which possesses any marked economical value. The best Vanilla is the produce of *V. planifolia*, a native of Mexico, but several other South American species are also used. About five or six cwt. are annually imported into this country.

Vanishing Fractions. [Fractions.]

Vanishing Groups, Method of. In Algebra, a method of reducing an algebraic function to the form of a sum of like powers, grouping the powers two and two together, and making each group vanish. One of the most interesting applications of the method is that by which the general algebraic equation of the n^{th} degree (n being greater than 4) can be deprived of its second, third, and fourth terms, simultaneously, by the solution of auxiliary equations, some of which rise above the third degree, or of its second, third, and fifth terms by the aid of equations, none of which rise above the fourth degree. In this way, the general equation of the fifth degree can, by the aid of equations of inferior degrees, be reduced to a trinomial form. The method, however, admits of other applications, as pointed out by its inventor, Mr. James Cockle. (*Cambridge and Dublin Math. Journal*, vols. ii. iii. vi. 1847–51.)

Vanishing Point. [Perspective.]

Vapour (Lat. vapor, perhaps akin to Gr. *καπνός*). When liquids and certain solids are heated they become converted into elastic fluids or *vapours*, which differ from *gases* in this respect, that they are not under common circumstances permanently elastic, but resume the liquid or solid form when cooled down to ordinary temperatures. The term *vapour* is frequently limited to water in the state in which it exists in our atmosphere and in other humid aëriform bodies, i. e. in a perfectly invisible state.

Different substances yield vapours with very different degrees of facility, or, in other words, are more or less volatile; a circumstance dependent, probably, upon the less or greater cohesion with which their particles adhere. Hence fluids are generally more volatile than solids, and hence solids generally pass into the liquid state before they assume the form of vapour. To both these statements there are, however, many exceptions; thus most of the expressed oils, being soluble only with great difficulty, are hence termed *fixed oils*. Common concentrated sulphuric acid is also a very fixed liquid, requiring a high temperature for its vaporisation; and camphor and some other solids evaporate at common temperatures, and arsenic and sal ammoniac at moderately high

temperatures, without previously assuming the liquid state. The space which vapours occupy always exceeds that of the substances from which they arise. Thus, at the temperature of 212°, and under a pressure of 30 inches of mercury, a cubic foot of water produces 1696 cubic feet of vapour, of alcohol 660, and of ether 443. Hence it is obvious that different vapours differ very considerably in density, and that this property is not directly as that of the liquids which furnish them. Thus, if we assume the density of air as 1000, that of aqueous vapour or steam is only 625; the density of aqueous vapour to that of atmospheric air being as 1000 to 1694. Again, assuming the density of air as = 1000, that of alcohol vapour is 1613, and of ether no less than 2586; though alcohol and ether are both, in the liquid state, lighter than water.

All vapours follow very nearly the same law of expansion, when heated, as gases, i.e. for every degree of Fahrenheit's thermometer they increase by $\frac{1}{491}$ of the volume which they occupied at 32°; but near their condensing points this coefficient becomes somewhat greater.

VAPOUR. In Physics, this term denotes the condition of a body when, its particles having acquired a repulsive force by the accession of heat, it is expanded to the state of an elastic fluid. Every liquid possesses the property of boiling at a certain determinate temperature, under the mean pressure of the atmosphere. Water, for example, boils at the temperature of 212° of Fahrenheit's scale, when the pressure of the atmosphere is equal to a column of mercury 30 inches in height; but under a diminished pressure it boils at a lower temperature; and by increasing the pressure, the temperature of the boiling point is increased. In the course of ebullition an elastic fluid, or vapour, is generated; and it is only when the tension of the vapour becomes equal to the pressure, that the action of boiling begins. But though ebullition and the consequent rapid formation of vapour take place only at a given temperature under a given pressure, vapour will rise from the surfaces of all liquids in free contact with the atmosphere at much lower temperatures. Water, for example, exposed in an open vessel, undergoes a gradual diminution of bulk, and is dissipated at temperatures far below the boiling point; and ice itself soon wastes away in the same insensible manner. This dissipation has been shown by Dalton to be occasioned by the formation of vapour of the same temperature as that of the water from which it proceeds, and having an elastic force equal to that of the vapour of water boiling at that temperature under a diminished pressure. Some liquids, ether for instance, require to be carefully secluded from the atmosphere to prevent their rapid evaporation.

Tension of Vapour at different Temperatures.—Dr. Dalton of Manchester was the first who ascertained by accurate experiments the elastic force of vapours at different temperatures below that of the point of ebullition. (*Manchester Memoirs*, vol. v. 1802.) The method which he employed consisted in introducing a portion of liquid into the vacuum of a barometer, where it floats on the surface of the mercury, and part of it is immediately converted into vapour. The tension of the vapour causes the mercury to descend; and the force of the tension is measured by the space through which the mercury falls, or by the difference of the height of the mercury in the tube in which the experiment is performed and its height in the common barometer. Dr. Dalton employed two barometric tubes plunged in the same cistern of mercury. Into one of these the liquid furnishing the vapour was introduced, the other serving the purpose of comparison; and in order that the experiment might be made at any determinate temperature, the two tubes were surrounded by another wider tube, into which water was poured of the temperature required. When the liquid on which the experiment was made was water, and the water surrounding the two barometric tubes was at the temperature of ebullition, the vapour formed in the tube caused the mercury to descend to the level of that in the cistern; whence it was inferred that at the temperature of ebullition the elastic force of aqueous vapour is precisely equal to the atmospheric pressure. A similar result was obtained when the experiment was performed with other liquids.

If the tube containing the portion of liquid be of considerable length, and the basin in which it is inverted of considerable depth, the pressure on the vapour above the mercury may be varied by raising or lowering the inverted tube. When the pressure is diminished in this way, it is found that so long as any liquid remains, new vapour of the same degree of tension will be generated, and the altitude of the mercury in the tube remain constant. On the other hand, an increase of pressure causes the condensation of a part of the vapour, and the mercury in the tube stands at the same height above that in the cistern. If the quantity of liquid in the barometric tube be so small that the whole is converted into vapour, it will be found that, on raising the tube and increasing the space in which the vapour is contained, the elastic force diminishes in proportion as the space is increased. The law of Boyle, therefore, applies to vapours as well as to the permanent gases [PNEUMATICS]; but with this distinction, that the vapours of all liquids, at a certain determinate temperature, have a maximum of density and tension which cannot be exceeded, and on attaining which they are condensed into the liquid form by any attempt to compress them further. It follows, therefore, that at a given temperature no more than a limited quantity of vapour can exist in a given space. This forms the criterion which distinguishes vapours from the permanent gases.

The results obtained by Dalton, in his experiments on the tension of aqueous vapour, are exhibited in the following table (*Manchester Memoirs*, 1802):—

Table showing the Maximum Tension of Aqueous Vapour at Temperatures below 212°, estimated in the Height of the Column of Mercury which they are capable of supporting.

Temperature	Tension in Inches of Mercury	Temperature	Tension in Inches of Mercury	Temperature	Tension in Inches of Mercury
2°	0·068	77°	0·91	152°	7·81
7	0·082	82	1·07	157	8·81
12	0·096	87	1·24	162	9·91
17	0·116	92	1·44	167	11·25
22	0·139	97	1·68	172	12·72
27	0·168	102	1·98	177	14·22
32	0·200	107	2·32	182	15·86
37	0·237	112	2·68	187	17·80
42	0·283	117	3·08	192	19·86
47	0·339	122	3·50	197	22·13
52	0·401	127	4·00	202	24·61
57	0·474	132	4·60	207	27·20
62	0·560	137	5·29	212	30·00
67	0·655	142	6·05		
72	0·770	147	6·87		

From this table the following formula for the elastic force or tension (which is measured by the pressure p) in terms of the degrees of temperature t, reckoned from 32°, has been deduced, which nearly represents the table, viz.

$$p = \cdot 1718\ (1 + \cdot 006\ t)^7.$$

In order to determine the tension of vapour at a temperature above the boiling point, it is necessary to have recourse to a different method of experimenting. By far the most satisfactory experiments hitherto made on this subject are those of Dulong and Arago in 1830, and of Regnault in 1844. As an account of these experiments, and a table of the results, have already been given in art. STEAM, it is here only necessary to remark, that the relation between the pressure and temperature (at least for all pressures exceeding four atmospheres) was found to be represented very nearly by the following empirical formula, viz.

$$p = (1 + 0\cdot 003974\ t)^5,$$

in which p denotes the tension or elasticity expressed in atmospheres, and t the degrees of temperature of Fahrenheit, counting from 212°.

It is evident from this empirical formula, as well as the numbers in the tables, that the tension of aqueous vapour increases in a much faster ratio than the temperature. This result appears to be general, and applicable to the elastic force of the vapours of all liquids, at least so far as may be judged from the imperfect experiments which have hitherto been made on the vapours of mercury, alcohol, and ether. Dalton thought that he had discovered a law which would establish a very simple relation among the tensions of the vapours of different liquids. It consists in this, that at an equal number of degrees above or below the point of ebullition corresponding to each liquid the elastic force of their vapours is equal. Thus, water boils at 212°, alcohol at 175°, and ether at 100°, the tension of the vapour at the boiling point being in all cases the same, and equal to the pressure of the atmosphere. Now, from the experiments of Dulong it appears that the tension of aqueous vapour is doubled when heated under pressure to 251°; i.e. by an increase of temperature of 39° above the boiling point. Hence, by the law of Dalton, the tension of the vapour of alcohol is equal to two atmospheres when its temperature is 175° + 39° = 214°; and that of ether equal to two atmospheres when the temperature is 100° + 39° = 139°. Dalton himself afterwards discovered that this law fails when the distances from the point of ebullition are considerable.

Density of Vapour.—The density of a vapour may be determined by introducing a known weight of the liquid which yields it into a receiver containing mercury, and inverting the receiver in a vessel also containing mercury, and tall enough to contain, above the mercury, a sufficient depth of water to cover the receiver. The whole apparatus is then heated; and when all the liquid in the inverted receiver has been evaporated, the space which the vapour occupies is measured, whilst at the same time the temperature of the surrounding water is noted. We have then a given bulk of vapour, the weight of which is the same as that of the liquid from which it has been produced, and consequently known. The temperature is also known; and the pressure is given in terms of the column of mercury in the receiver, and the height of the surrounding fluid compared with the indication of the barometer. In this manner the density is found; and when the density of a vapour at a given temperature and under a given pressure has been determined, its density under any other pressure, and at its corresponding temperature, may be calculated in the following manner: Let a = the constant coefficient of dilation = ·00204 (it being found by experiment that vapour out of contact with liquid expands or contracts at the same rate with permanently elastic fluids by variations of temperature, i.e. by $\frac{1}{491}$ of its volume for each degree of Fahrenheit's scale), t = the number of degrees of Fahrenheit's thermometer above 32°, v = the volume, p = the pressure, and d = the density of a vapour at the temperature of 32°; and let v', p', and d' be respectively the volume, pressure, and density at another temperature, 32° + t. We have then $v' = (1 + a\,t)\,v$. Now, when the pressure is constant, the density is inversely as its volume; and, by the law of Boyle, the density of a gas or vapour is directly as the pressure; whence $\frac{d'}{d} = \frac{p'}{p} \times \frac{v}{v'}$, and consequently $\frac{d'}{d} = \frac{p'}{p(1 + a t)}$, or $d' = \frac{d\,p'}{p(1 + a t)}$. If we compare the density of aqueous vapour at any temperature with its density at the boiling point of water, which is 180° above the freezing point, and put d'' = the density, and p'' = the pressure at the boiling point, the formula becomes $d' = \frac{d''\,p'\,(1 + 180\,a)}{p''\,(1 + a\,t)}$. The following table, computed from this formula,

with Dalton's values of the pressures, shows the density and volume of aqueous vapour, at its maximum tension, for every ninth degree of temperature from the freezing to the boiling point. The unit of density is water at the temperature of 32°; and the unit of volume the volume of an equal weight of water also at 32°. As the density is inversely proportional to the volume, the numbers in the last two columns are the reciprocals of each other. They differ slightly from the numbers given by Gay-Lussac.

Temperature	Density	Volume
32°	·0000053	188600
41	·0000073	137000
50	·0000097	103000
59	·0000131	76330
68	·0000173	57800
77	·0000227	44050
86	·0000297	33670

203	·0005074	1971
212	·0005896	1696

By means of this table we may calculate the weight of water that would be contained in the form of vapour of the maximum tension in any given volume—a calculation which is frequently required in meteorological enquiries.

The phenomena of vapour have been studied with reference to two objects; the condition of the atmosphere as to moisture, and the properties of steam as a moving power in machinery. On the subject of vapour in connection with the first of these objects, see Daniell's *Meteorological Essays*; Davy's *Elements of Agricultural Chemistry*. [Dew; Evaporation; Hygrometry.] See also *Greenwich Meteor. Obs.* For experiments on the elasticity and density of aqueous vapour, see, in addition to the Memoirs of Dalton and of Arago and Dulong, already cited, Robinson's *Mechanical Philosophy*; Ure, in the *Philosophical Transactions* for 1818; Pouillet, *Traité de Physique*; Despretz, *Traité de Physique*; Gheler's *Physikalisches Wörterbuch*, art. 'Dampf,' by Prof. Muncke. [Steam.]

Varangians. A name employed by the Greek historians to designate the Teutonic guards of the Byzantine emperors. The name, which passes through the Low Latin forms wargus, wargengus, warengangi, &c., has by some been traced to the old Teutonic *varg*, a wanderer or exile, while others suppose it to be the same with *Franks*. Harald Hardrada, king of Norway, who fell at the battle of Stamford Bridge, had served among the Varangians at Constantinople; and after the Norman conquest of England their ranks were, according to the statement of Ordericus Vitalis, recruited by numbers of Englishmen who found their way into the Byzantine territories. (Thierry, *Conquête de l'Angleterre par les Normands*, livre v.)

Varec. The impure carbonate of soda, made in Brittany: it is also sometimes called *Blanquette*: it corresponds to our *Kelp*.

Variable Quantity. In Analysis, a quantity conceived to be in a state of increase or diminution, or to have different values in the same equation. Thus, the abscissa and ordinates of a curve are variable quantities, because they have different values for every different point in the curve, and in passing from one point to another their values increase or diminish according to the law of the curve. In the equation of the circle $y = \sqrt{(2\,a\,x - x^2)}$, x and y are variables; for x may have any value whatever between 0 and $2\,a$, and there will be a corresponding value of y, which satisfies the equation. The quantity a is a *constant* quantity, and remains the same, whatever be the values of x and y. It represents, in fact, the radius of the circle.

Variance (Lat. variantia). In Law, a difference of statement between two material documents in a cause; as where the plaintiff's declaration differs from a deed on which it is grounded. Accidental slips of this nature were formerly often fatal, but the courts have now power to amend variances, and this power is so liberally exercised that the subject has lost much of its importance.

Variation (Lat. variatio). In Music, a different manner of performing the same air or melody. Airs with variations have always been favourite subjects for composition, and the works of almost all eminent musicians abound in examples of varied airs, showing great musical skill.

Variation of the Compass. The angle which the magnetic needle makes with the plane of the true meridian. It is otherwise called the *declination*. [Declination of the Magnetic Needle.] For tables showing the variation of a great number of places, and its progressive, annual, and diurnal changes, see Brewster's *Treatise on Magnetism*, 1837, reprinted from the *Encyclopædia Britannica*, and *Greenwich Magnet. Obs.*

Variation of Curvature. In Geometry, the change which takes place in the curvature in passing from one point of a curve to another. The circle is the only curve in which the curvature is the same at every point. The curvature of a curved line at any point is the same as that of the osculating circle at that point. But the curvature of a circle is inversely as its radius: hence the curvature of any curve is

inversely proportional to the radius of curvature; and, consequently, the variation of the curvature is proportional directly to the differential of the radius, and inversely to the square of the radius of curvature. In the conic sections, the variation of curvature at any point is proportional to the tangent of the angle included between the diameter and the normal, which pass through that point.

Variation of the Moon. In Astronomy, an inequality of the moon's motion, depending on the angular distance of the moon from the sun. It arises from that part of the sun's disturbing force which is at right angles to the radius vector, and which accelerates the motion of the moon from the quadratures to the syzygies, and retards it from the syzygies to the quadratures. It is proportional to the sine of twice the angular distance between the sun and moon; and its maximum value, or the coefficient of its arguments, is 35′ 41·9″. Hence it is represented by the formula (35′ 41·9′) sin 2 A, A being the angular distance of the moon from the sun. The variation was discovered by Tycho Brahe. It had escaped the observation of Hipparchus and the ancient astronomers, though of sufficient magnitude to have been sensible to them; probably because they chiefly observed the moon in the syzygies and quadratures, and at these points of the orbit its value is nothing.

Variation of Parameters. [PARAMETERS, VARIATION OF.]

Variations. In Algebra, the different *arrangements* of a set of objects into groups of given magnitude, which differ either in the objects which they contain or in the order in which these objects are arranged. The term *permutation* is sometimes used in place of variation, though by permutations are generally understood variations each of which contains all the objects. [PERMUTATIONS.] The number of variations, m in each, of n different objects is the product of the m successive factors $n\ (n-1)\ .\ .\ .\ (n-m+1)$. Thus, there are $3 \times 2=6$ variations of three letters a, b, c, when taken in pairs; they are ab, ba, ac, ca, bc, cb. Combinations differ from permutations inasmuch as the order of the objects in each group is disregarded. [COMBINATIONS.] Hence each permutation of a combination is a variation, and the three are connected by the simple relation C . P = V, where C and V are, respectively, the numbers of combinations and variations that can be formed from n things by taking m together, and P the number of permutations of m things. With a sufficient supply of each of the n different objects n^m different variations, m in each, can be formed, provided objects of the same kind may also enter into a variation.

Variations, Calculus of. An important branch of Modern Mathematics, developed by Lagrange, the principal object of which is to resolve in a general manner certain classes of questions respecting *maxima* and *minima*, the solution of which cannot be obtained by the ordinary processes of the differential calculus. In solving problems of maxima and minima by the differential calculus, it is necessary to find the determinate values of the different variables which enter into a proposed finite function of those variables, in order that the proposed function may have the greatest or least value possible. Many problems of this nature are met with in the writings of the ancient geometers, particularly in the Conics of Apollonius; and the application of algebra to geometry gave rise, about the middle of the seventeenth century, to many others, proposed and solved by Fermat, Slusius, Hudde, and others. As no general method of solving such questions was known before the invention of the differential calculus, their solution was accomplished by particular artifices, and was frequently attained with very considerable difficulty. This difficulty was removed for the class of questions now mentioned by the invention of the calculus; but as the instrument of investigation was improved, new views were opened, and a more difficult class of questions was proposed, to which the known methods seemed inapplicable. It was proposed to find, among all curves subjected to a given law, that which best fulfilled a given condition: for example, to find the curve which, under given conditions, encloses the greatest space; to find the curve along which a heavy body must descend in order to pass from one given point to another given point in the least time possible, &c. In such questions the relations between the variables is not given, as in the ordinary cases of maxima and minima; the object proposed being to find that relation, or to find the equation which must subsist between the variables in order that the condition of maximum or minimum may be fulfilled.

The first problem of this kind which was solved appears to have been that of the solid of least resistance. In the first edition of the *Principia*, published in 1687, Newton gave the equation of the curve by the rotation of which about its axis that solid is formed which, when moved through a fluid in the direction of the axis, is less resisted than any other body of the same specific gravity and bulk; but he did so without demonstration or indication of the views by which he had been guided. About ten years later the famous question of the BRACHISTOCHRONE, or curve of quickest descent, was agitated between the two brothers James and John Bernoulli, in which Leibnitz and some of the other most illustrious mathematicians of the day took a part. The more general problem of *isoperimeters* was solved by James Bernoulli in 1701; and it was in the analysis which he gave on this occasion that the principle on which the solution of similar questions depends was first distinctly unfolded. Euler treated the whole subject in his peculiarly luminous manner in a treatise published in 1744, under the title *Methodus Inveniendi Lineas Curvas Maximi Minimive Proprietate Gaudentes*. And,

lastly, the method was reduced to its utmost simplicity by Lagrange, who supplied the algorithm, and gave to it the form under which it is now exhibited as the Calculus of Variations.

We shall confine ourselves here to the briefest possible statement of the first principles of the calculus, and then refer the reader to the best works on the subject. The differential calculus investigates the changes which a function undergoes when the variables of that function receive infinitesimal increments; the more especial object of the calculus of variations, however, is the investigation of the change which a function suffers when its *form* is altered. The form of a function u being conceived to change continuously, the change in its value, due to an infinitesimal change in form, is denoted by δu, and called its *variation*, just as its change in value due to infinitesimal changes in the values of its variables is denoted by du, and called its *differential*.

One of the principal objects of the calculus is to find the variations of integrals of given expressions, and the forms which the indeterminate functions involved in those integrals must have in order that the latter may possess maximum or minimum values. In solving such problems the following two important principles are frequently applied: The variation of a differential is equal to the differential of a variation, and the variation of an integral (which must vanish for maximum or minimum values) is equal to the integral of a variation. These principles are expressed by the symbolical equations $\delta d = d\delta$ and $\delta\int = \int\delta$.

The complete treatises on the subject are those of Jellet (Dublin 1850); Strauch, *Theorie und Anwendung des sogenannten Variations-calcul's*, Zurich, 1854 (distinguished by its rich collection of worked examples); Stegmann, *Lehrbuch der Variations-rechnung* (Kassel 1854); and the *Calcul des Variations*, now publishing by Moigno and Lindeloef. We have also, in English, two excellent critical histories of the calculus: the first, by Woodhouse, is entitled *A Treatise on Isoperimetrical Problems and the Calculus of Variations* (Cambridge 1810), and gives the history of the calculus from its origin to the close of the last century; the second, by Todhunter (Cambridge 1861), gives a very complete account of the progress made during the present century. These works will furnish the reader with full references to the many important investigations on the subject.

Varicella. [CHICKEN-POX.]

Varicocele (a word coined from the Lat. varix, *a distended vein*, and Gr. κήλη, *a tumour*). A swelling of the veins of the spermatic cord.

Variegated Copper-ore. [ERUBESCITE.]

Variety (Lat. varietas). In Zoology, this term is applied to individuals of the same species, which, from the operation of different causes, as age, climate, food, locality, domestication, &c., present deviations from the specific type in size, colour, form, and relative proportion of parts of the body; but have the capacity of reverting to the original specific form in successive generations, on the cessation of the influences under which the variety originated.

Variola. [SMALLPOX.]

Variolite. A variety of Felspar, generally of a dark green colour speckled with grey; but sometimes exhibiting white, blue, red, and other intermediate tints. The name (from variola, the smallpox) has reference to the remarkable appearance presented by weathered surfaces of the stone, which display projecting black spots or points, each surrounded by a brown (sometimes by a white) ring, and occasionally even by a second whitish circle. Large masses of this stone are obtained from the High Alps, and it is also found in France, Switzerland, Savoy, and in co. Antrim, Ireland. Variolite takes a beautiful polish, and is used in that state for ornamenting cabinets, for caskets, snuff-boxes, &c.

Variolous. In Zoology, when a part is beset with many shallow impressions like marks of the variola or smallpox.

Variorum Editions. In Bibliography, certain editions of the classic authors of antiquity, published chiefly in Holland, in the seventeenth and eighteenth centuries, and containing the notes of numerous commentators. These editions are chiefly valued by collectors.

Variscite (from Variscia, the Latin name for Voigtland). An apple-green mineral forming a reniform incrustation on flinty slate at Messbach in Voigtland.

Varix (Lat.). A dilatation or swelling of a vein.

Varnish (this word may perhaps be another form of *burnish*; but Sir G. C. Lewis gives the following account of the term: Upon the return of Ptolemy Euergetes, king of Egypt, from his Syrian expedition in 243 B.C., his Queen Berenice dedicated a lock of her hair in the temple of Aphrodite at Zephyrium; this lock, having disappeared from the temple, was translated by Conon into the heaven as a constellation, which bears the name of Coma Berenices, and its fame has been perpetuated in the word *vernice*, *vernis*, and *varnish*, which alludes to the amber colour of the queen's beautiful tresses: *Astronomy of the Ancients*, ch. iii. sect. 14). A fluid which when spread thin upon a solid surface becomes dry, and forms a coating impervious to air and moisture. There are two kinds of varnish; viz. *spirit* and *oil varnishes*: methylated spirit is used for the former; and for the latter, fixed and volatile oils, or mixtures of the two. The solid substances which are dissolved in the above menstrua, and constitute the *body* of the varnish, are almost exclusively resinous, and are chiefly the following: 1. *Turpentine*, all the varieties of which are employed by the varnisher: they form an excellent body, and give strength and glossiness at a small expense; but they do not dry without other additions. 2. *Copal*, a peculiar resin, very diffi-

cult to dissolve, but forming a hard and durable ingredient. It is generally melted over a gentle fire previous to use. 3. *Lac*, which gives great toughness and hardness; but is often inadmissible, on account of its reddish brown colour. 4. *Mastic*, which yields a tough, hard, brilliant, and colourless varnish. 5. *Elemi*, a resin of a pale yellow green tint, and a valuable ingredient, on account of its toughness and durability. 6. *Sandarach*, a resin which imparts splendour, but which alone is not durable. 7. *Amber*, a valuable ingredient, on account of its hardness and durability; but difficult of transparent solution, and hence chiefly used in opaque varnishes. 8. *Benzoin*, added on account of its fragrancy. 9. *Anime*, which gives brilliancy and some scent. 10. *Gamboge*, for yellow varnishes. 11. *Dragon's blood*, for red varnish. These, together with turmeric, saffron, and annatto, are used chiefly on account of their colour, and to cover brass and copper under the name of *lacquers*. 12. *Caoutchouc*. This extraordinary vegetable product has of late been much employed in a variety of preparations used as varnishes. It is invaluable where materials are to be rendered air-tight, and where at the same time flexibility, and even elasticity, are required; but its principal application in this way is in the manufacture of various *waterproof* articles. 13. *Asphaltum*, the varieties of which are indispensable in black oil varnishes. In making spirit varnishes, the strongest methylated spirit of commerce should be used (of a specific gravity not exceeding 820), and its solvent power over some of the more intractable resins is sometimes improved by the addition of a little camphor; in order to prevent the agglutination of the resin, it is often necessary to mix it with sand or pounded glass, by which the surface is much increased, and the solvent energy of the spirit facilitated. The proportions in which the several ingredients are used, and the selections for particular purposes, are infinitely various.

Varuna. [URANUS.]

Varvicite. An ore of manganese found in slightly radiating, fibro-lamellar masses, of a steel-grey colour and a sub-metallic lustre, at Hartshill in Warwickshire. It is probably a mixture of Pyrolusite and Psilomelane or Manganite; the former of which it resembles in hardness, and the latter in appearance. 'The name was devised by the late Richard Phillips, to facilitate the pronunciation by foreigners of the word *Warwick* (*Varvic*), the locality after which the mineral was called.' (Bristow's *Glossary of Mineralogy.*)

Vascular System (Lat. vascularius, from vasculum, dim. of vas, vasis, *a vessel*). In Botany, that portion of the tissue of plants which is destined for the conveyance of air. Vascular plants are those in which the vascular system occurs, or forms a principal feature. The air-vessels are the tracheæ or spirals.

Vase (Lat. vas, vasis). In Sculpture, a vessel usually ornamented with sculpture of fruits, flowers, bassi-rilievi, &c.

Vases, Etruscan. In Antiquities, these well-known and beautiful objects of ancient art have been discovered in great numbers, chiefly in the sepulchres of ancient Italian cities. Their material is terra cotta, and they are painted with figures and scenes. The most beautiful, and indeed the most numerous, were formerly obtained from Campania and Magna Græcia; and it was much controverted among antiquarians whether the workmanship was not originally Greek. (Sir W. Gell, *Topography of Rome*, vol. i.) Of late years, the great sources have been the sepulchres of Etruria Proper. Five thousand have been taken in twenty-five years from the ruins of Tarquinii alone; and it seems to be now generally admitted that the manufacture is rightly called Etruscan; that it is of extreme antiquity; that in its progress Greek taste and style were introduced; and that the art had fallen into disuse in the flourishing period of the Roman empire. (Dennis, *Cities and Cemeteries of Etruria*; Mrs. H. Gray, *Sepulchres of Etruria*, p. 45.)

Vase-painting. Terra cotta vases are of two kinds generally—the black and the yellow; so distinguished from their painted decorations. In the black vases, which are the most ancient, the figures are covered with a black varnish, while the ground is left the colour of the clay; in the yellow, the figures, drawn in outline, are left the colour of the clay, while the ground is covered with the black varnish. The former are decorated with skiagrams (or silhouettes), the latter with monograms. Other varieties of vase-paintings exist, but they are exceedingly rare. [PAINTING.]

Vasodentine (Lat. vas, *a vessel*; dens, *a tooth*). In Anatomy, that modification of dentine in which capillary tracts of the primitive vascular pulp remain uncalcified, and carry red blood into the substance of the tissue. They form the so-called vascular or medullary canals, and are usually more or less parallel in their course. A large proportion of the central part of the tooth of the sloth and megatherium consists of vasodentine, and a smaller proportion of the same part of the tusks of the elephant and of the scalpriform incisors of the rodents.

Vassal (Fr.; Ital. vassallo, derived, according to Sir F. Palgrave *On the English Commonwealth*, from the Welsh gwâs, *a young man or page*; gwasâeth, *the state of pagehood*, being rendered in Latin vassaticum). The holder of a fief, by fealty and service, of a feudal superior or lord. [FEUDAL SYSTEM.] From the Celtic origin of this word, it has been inferred that some portion of the feudal usages were derived from those of the tribes which possessed Gaul and Britain before their annexation to the Roman empire. In the ancient documents of the Carolingian kings, the vassal is termed *vassus* or *homo fidelis*; the lord generally *senior*. The term *vassal* was also more generally used, in common language, to signify all who were dependent on a superior lord, from those who

held fiefs of him down to his serfs or villeins. (Guizot, *Civilisation en France*, vol. iv.)

Vastus (Lat.). A term applied by anatomists to two muscles of the thigh, the *external* and *internal vasti*.

Vateria (after Abraham Vater, a German botanical author). A genus of Indian trees of the order *Dipterocarpaceæ*. *V. indica* yields a useful gum-resin known as Indian Copal, Piney Varnish, White Dammer or Gumanine. The resin is procured by cutting a notch in the tree, so that the juice may flow out and become hardened by exposure to the air. It is employed in India as a varnish, and on the Malabar coast is used in the manufacture of candles, which burn with a clear light and an agreeable fragrance, and do not require snuffing. The Portuguese employ the resin instead of incense. Ornaments are fashioned from it under the name of *amber*. Medicinally it is employed in rheumatic and other affections. The timber is in request for building purposes.

Vatican. The palace of the popes, known by this name, stands on the right bank of the Tiber in Rome, and on the hill anciently called by the same name. Some say that it was begun by Pope Symmachus. It was inhabited by Charlemagne in 800; and the present irregular edifice has been raised by the gradual additions of a long series of pontiffs. (Milman's *Latin Christianity*, vol. iv. p. 452.) Its extent is enormous, the number of rooms, at the lowest computation, amounting to 4,422. Its marbles, bronzes, frescoes, statues, gems, and paintings, are unequalled in the world; and its library is the richest in Europe in manuscripts. The length of the museum of statues alone is computed to be a mile. Here are the Sistine Chapel; the Camere of Raphael, painted by himself and his pupils; the museum of Pius VI., peculiarly rich in objects of ancient Italian workmanship; and other deposits of art and antiquity, each of which by itself would suffice to render a city illustrious.

Vauban's Systems. [FORTIFICATION.]

Vaudeville. In French Poetry, a species of light song, frequently of a satirical turn, consisting of several couplets and a refrain or burden, introduced into theatrical pieces. The origin of the word is disputed; some derive it from Vau-de-Vire, a village in Normandy. Short comic pieces interspersed with such songs are also termed *vaudevilles*.

Vaudois. The inhabitants of some valleys of the Alps, lying in Piedmont between the Po and the Dora Riparia, whence they derive their name. They must be distinguished from the Waldenses, or followers of Peter Waldo, who acquired celebrity in the twelfth century, and from whom some writers have deduced both their religious tenets and their appellation also. (Milman, *Latin Christianity*, books viii. ix.) It has been asserted by some theologians that the true spirit of the primitive Christianity was kept alive among the Vaudois throughout the whole period of Romish corruption. This position, however, does not seem susceptible of proof. For three centuries they were viewed with displeasure by the dukes of Savoy and kings of Sardinia, their masters, and repeatedly visited with military execution, or more legal forms of violence. One great persecution, in the seventeenth century, is known to us by Milton's noble sonnet. Not long after it they were altogether expelled, and retreated into Switzerland, whence they returned by a celebrated march, and recovered their valleys by force; an event commemorated in the work of Arnaud, one of their pastors, *La Glorieuse Rentrée des Vaudois dans leurs Vallées*. Since 1848, however, they have been freed from all religious disabilities, and have spread beyond their original seat in the valleys of Luserna and St. Martin with the tributary branches. Vaudois churches have been established in some of the principal Italian cities. The language of the people is French, owing to their long connection with French and Swiss Protestants, which has caused that tongue to be used in their church service.

Vault (Fr. voûte, Ital. volta). In Architecture, an arched roof, so contrived that the stones, bricks, or other materials used in its construction, sustain and keep each other in their places. Vaults are circular and elliptical. When their section rises higher than a semicircle, they are said to be *surmounted*; when less, *surbased*.

Vauquelinite. The native chromate of copper and lead, composed (when pure) of 27·9 per cent. of chromic acid, 10·9 oxide of copper, and 61·2 oxide of lead. It occurs in small (generally macled) crystals, and in mammillated masses forming thin crusts, which are sometimes hollow and approaching to stalactitic. The colour is black (occasionally with a tinge of green or brown), and it is faintly translucent or opaque. It is chiefly found at Beresow in Siberia on Quartz; Pont Gibaud in Auvergne; at Congonhas do Campo in Brazil, and at the Sing-sing lead mine in New York. Named in honour of Vauquelin, the celebrated French chemist.

Vavassor (sometimes written *valvasor*, and *valvasour*, in old books). A word of uncertain derivation, but springing possibly from the same root with VASSAL). The vassals who held immediately of the higher nobility, under the feudal system in France, were frequently comprehended under this general name; the châtelains being such vavassors as possessed castles or fortified houses. (Hallam, *Middle Ages*, vol. i. p. 149.) The word, however, seems to have been of very loose application. Poor gentlemen are termed *vavassors* in old French romances. In England the title was not commonly used, although it is mentioned in Bracton in contradistinction to *baron*, and sometimes appears to have designated persons who held land by military tenure of others than the king. (*Archæologia*, vol. ii.)

Vector (Lat. *one who bears*). A directed line in space of definite length. [QUATERNIONS.] The more frequently occurring expression

radius vector has been already explained. [Co-ordinates; Radius Vector.]

Vectorial Angle. [Co-ordinates.]

Veda. The name given to the collective sacred literature of the Brahmans. The Vedas, more properly so called, are four in number: the Rig-Veda, the Yajur-Veda, the Sama-Veda, and the Atharva-Veda. These four works, each being a *sankita*, or collection, complete in itself, contain the substance or kernel of the Hindu faith, and round these has grown up a vast literature, which is also included under the general term *veda*, or knowledge. These four sanhitas are illustrated and commented upon in the Brahmanas, Suktas, Upanishads, Pratisakhyas, Vedangas, and in scholia of singular minuteness. This literature, which as a whole is now rarely mastered even by the Brahmans, is divided into two great classes, the Sruti, or literature of revelation, and the Smriti, or literature of tradition. This latter class contains the Sutras, or precepts which form the Vedangas or *members* of the Veda, these Vedangas, usually reckoned as six in number, being elaborate treatises on (1) Siksha, *pronunciation*; (2) Chandas, or *metre*; (3) Vyakarana, *grammar*; (5) Jyotisha, *astronomy*; (6) Kalpa, *ceremonial*. The contents of all these works are tabulated in systematic indices or Anukramanis, the most perfect of these still extant being that of the Rig-Veda, attributed to Katyayana; and called the Sarvanukrama, or universal index. The period assigned to this Sutra literature, by Professor Max Müller, extends from the second to the seventh century before the Christian era.

The periods preceding the Sutras comprise the literature of revelation. The first of these periods is that of the Brahmanas, which are subdivided into Karma Kanda, and Jnana Kanda (i.e. *practice* and *speculation*): the former term denoting the prayers, hymns, and formulæ to be recited at the sacrifice; the second, enquiries into the nature of man and of God, and the relations of matter and spirit. But, although the definition of the Brahmanas is too vague and comprehensive to constitute a special characteristic, there is evidence enough to show that they are the work of many persons, all striving to develope a system of Brahmanical Hinduism which is at best only faintly indicated in the earliest Vedic verses. The period assigned to this portion of Vedic literature by Professor Müller is only two centuries: by Prof. H. H. Wilson it is extended to the tenth or eleventh century B.C.

The period next preceding brings us to the Veda proper, the collection of hymns, prayers, formulæ, and ritual injunctions, known by the name of Mantra, and brought together in the Sanhitas or collections of the four Vedas. But of these the fourth is regarded by the Hindus themselves as of doubtful authority, and of the rest the Yajur-Veda and Sama-Veda are to be regarded as long posterior to the Rig-Veda, to which we must look for the most authentic and primitive representation of Hindu faith. This Rig-Veda is a collection of material compositions varying in date and authorship, some of which are to be recited at sacrifices, usually by priests termed *Hotri*, while others make not the slightest reference to any ceremonial or the existence of any sacerdotal order.

To this Mantra period Professor Max Müller adds one still earlier, the Chandas, i.e. the age in which the earliest songs were composed, and to which we must look for the germs of later Hindu theology and philosophy. It is in this period that the chief interest of Vedic literature centres for the western student. The songs of this age exhibit, in Professor Max Müller's words, 'the most ancient chapter in the history of the human intellect,' so that 'if this collection had been written but fifty years ago in some distant part of the world untouched by the general stream of civilisation, we should still call it more ancient than the Homeric poems, because it represents an earlier phase of human thought and feeling.' Hence the paramount value of these songs not only as indicating the belief of the earliest Hindu inhabitants of India on the nature of God, of law, of human duty and human destiny, but as exhibiting the germs out of which grew up the mythical systems of the eastern and western world. Without this literature the science of comparative mythology 'would have remained mere guess-work, without fixed principles and without a safe basis.' With it the refutation seems to be furnished of speculations which find in the mythical system of the Greeks a wilful perversion of doctrines clearly and distinctly revealed. 'Names which in Homer have become petrified and mythological are to be found in the Veda, as it were in a still fluid state. They next appear as appellations, not yet as proper names; they are organic, not yet broken and smoothed down.' The value of this collection is still further enhanced by the fact that even 'these earliest specimens of Vedic poetry belong, as has been said by Bunsen, to the modern history of the human race,' and thus a further light is thrown on the mode in which a knowledge of the conditions of human existence, and of their relation to the Unseen Maker and Preserver of all things, dawned upon the minds of men.

For further details, and for the bibliography of the subject, the reader is referred to Prof. Max Müller's *History of Sanskrit Literature*, and to Prof. H. H. Wilson, *Edin. Rev.* Oct. 1860.

Vedangas. [Veda.]

Vedanta. A sect among the Hindus, whose philosophy is professedly founded on the revelations contained in the Vedas. Their belief exhibits a close resemblance to the Quietism of European thinkers.

Vedette. [Vidette.]

Veer Out. In Naval Language, to give the ship more scope of cable. Also to let anything drop astern by a rope. *To veer* is also the old term for *to wear*.

Vegetable (Lat. vegetabilis, from vegetare, *to enliven*). One of the names of that division

or kingdom of animated nature which consists of plants. Thus the term *vegetable kingdom* is equivalent to *the kingdom of plants*. The properties, qualities, and substance of plants are distinguished from those of animals by the use of the term *vegetable*, as *vegetable juices*, *vegetable products*, &c.

In a more especial and colloquial sense, the term *vegetable* is used to indicate those particular plants which are used as esculents, these forming what is called *vegetable diet*. In this sense it includes the potato, cabbage, cauliflower, pea, bean, spinach, and such like, but does not embrace fruits properly so called, as the apple, pear, grape, &c., although these are included in its more extended sense, as embracing the whole vegetable kingdom. [BOTANY.]

Vegetable Earth. Soil in which decayed vegetable matter is in a much larger proportion than the primitive earths. In Horticulture, vegetable earth is called *mould*; and in Agriculture the term is applied to the surface soil of hollows, which contain alluvial soil beneath, and vegetable matter, generally of a black colour, on the surface.

Vegetable Flannel. A textile material largely manufactured in Germany from the *Pinus sylvestris*. A great number of persons are employed in the various processes of separating the fibre from the oil. The fibre, locally called *wold-wold*, is spun, knitted, and woven into various fabrics. It is said to be highly efficacious in restoring the function of the skin to its normal condition.

Vegetable Gold. An acid extracted from the roots of *Trixis Pipizahuac*.

Vegetable Hair. One of the names of the *Tillandsia usneoides*.

Vegetable Ivory. The albumen of the nut of *Phytelephas macrocarpa*.

Vegetable Marrow. The Succade Gourd, one of the many forms of *Cucurbita Pepo*.

Vegetable Parchment. The same as Papyrin, a substance resembling parchment, produced by immersing bibulous paper in dilute sulphuric acid. [PAPYRIN.]

Vegetable Sheep. A New Zealand name for *Raoulia eximia*, a composite plant growing on the mountain sides, where it forms woolly cushion-like masses resembling sheep.

Vegetable Silk. A cotton-like material obtained from the seed-pods of *Chorisia speciosa*.

Vegetable Tallow. A fatty substance obtained from *Stillingia sebifera*, *Vateria indica*, and other plants.

Vegetable Wax. A kind of wax obtained from the berries of several species of *Myrica*, especially *M. cerifera*. It is sometimes called *Myrtle Wax*, from the name of Candleberry Myrtle applied to *Myrica*.

Vegetal (Lat. vegetus, *lively*). In Physiology, this word is used to denote the class of vital phenomena common to plants and animals; viz. digestion and nutritive assimilation, growth, absorption, secretion, excretion, circulation, respiration, generation, as contradistinguished from a second class of vital phenomena, viz. sensation and volition, peculiar to animals: the first are called the *vegetal functions*, the second *the animal functions*; and the powers or forces on which they depend have been termed respectively the *vegetal life* and the *animal life*.

Vegetation. A general term designating plants as a group of organised beings distinguished from animals. [BOTANY.]

Vegetation, Chemistry of. From the moment when a seed begins to grow, a series of chemical changes are induced, essential to the developement of its germ. A general outline of the process has been given in art. GERMINATION.

Vehmic Courts (Ger. vehm or femgerichte). Criminal courts of justice, established in Germany during the middle ages. These courts are commonly said to have originated in those held by the Missi Dominici, or imperial legates, sent by Charlemagne into the provinces of his empire; but many circumstances point to their descent from the more ancient tribunals of the German tribes, held in the open air in the primitive periods of their history. (See a curious account of the free field courts of the Germans in Sir F. Palgrave's work on the *English Commonwealth*; Wigand's *Femgericht Westphalens*.) But the character under which these institutions became formidable and important, about the beginning of the thirteenth century, arose from the disordered state of Northern Germany, after the dissolution of the duchy of Saxony. The Vehmic, or, as they were called, free courts, were then modelled on a secret system of organisation. The president was usually a prince or count of the empire; his assistants (styled *Freischöffen*) were persons affiliated to the society by secret initiation, to the number, it is said, at one time of 100,000. All these were bound to attend the secret meetings of the courts when summoned, and to execute their decrees, if necessary, by taking the life of persons condemned. Westphalia, styled, in the language of the free courts, the *Red Land*, was the district in which their central authority was seated. These courts exercised a great power, which was occasionally serviceable in repressing the lawless violence of the nobles of that period, but which was also liable to be perverted to the gratification of private malice and tyranny. Thus, a Vehmic sentence decreed the death of Charles the Bold, duke of Burgundy. Various leagues were formed in the fifteenth century, by the nobles of the empire, for the purpose of destroying their influence: this was at last effected, chiefly by the introduction of a better system of public judicature and police in the several states.

Veil (Lat. velum). In Botany, a term used in describing fungi to denote the horizontal membrane connecting the margin of the pileus with the stipes.

Veins (Lat. venae). In Anatomy, elastic tubes which convey the blood from the arteries back to the HEART.

Veins, Mineral. [MINERAL VEINS.]

Velati. [ACCENSI.]

Velella (a word coined from the Lat. vela, *sails*). The name of a genus of Acalephes, characterised by a vertical crest or sail, by means of which they are wafted along the surface of the ocean.

Velites (Lat.). The light-armed infantry attached to a Roman legion were so called. (*Mém. de l'Acad. des Inscr.* vol. xxix.) They were equipped with bows, slings, and javelins, a light wooden buckler covered with leather and a head-piece.

Vellum (Fr. vélin, from Lat. vitulinus). A fine kind of parchment made of calfskin. The skins are limed, shaved, washed, and stretched in proper frames, where they are scraped with the currier's fleshing-tool, and ultimately rubbed down to a proper thickness with pumice-stone.

Veloce (Ital. *swift*). In Music, a term which, prefixed to a movement, indicates that it is to be performed in a rapid manner.

Velocipede (Lat. velox, *swift*, and pes, *a foot*). A vehicle invented at Mannheim in 1817, by M. Drais, consisting of a piece of wood about five feet long, and half a foot wide, resting on two wheels, one behind the other. On this a man sits, as on horseback, his feet touching the ground, and thus propelling the machine. The front wheel may be turned at pleasure, so that the rider may give any direction to the machine. Velocipedes are still sometimes seen: they are now usually made with four wheels, with a seat for the rider, who propels himself by the action of his feet on treddles connected with crank axles on the principle of the common foot lathe.

Velocities, Virtual. [VIRTUAL VELOCITY.]

Velocity (Lat. velocitas, from velox, *swift*). Velocity is measured by the space through which a moving body passes in a given time. The velocity of a body is uniform when it passes through equal spaces in equal times; and variable when the spaces passed through in equal times are unequal. It is accelerated when the force by which a body is put into a state of motion continues to act after the motion has commenced; and retarded when the moving body encounters obstacles which tend to destroy its motion. Velocity is merely a relative term; for there is nothing, as Biot remarks (*Traité de Physique*, l. iii. p. 148), which in itself is either swift or slow, any more than great or small. The velocity of an express train appears very great, yet it is slow in comparison with the motion of a point on the earth's equator carried round by the diurnal motion; and this, in its turn, is far inferior to the velocity of the earth in its orbit, which again is greatly exceeded by the velocity of light. For the velocity of falling bodies, see ACCELERATION; for the velocity of a body moving in a curve about a centre of force, see CENTRAL FORCES. [FINAL VELOCITY; GUNNERY; INITIAL VELOCITY; TERMINAL VELOCITY; VIRTUAL VELOCITY.]

Velocity, Angular. In Kinematics, angular velocity, in uniform motion around an axis, is measured by the ratio of the arc, described in every unit of time by any particle of the rotating body, to the distance of that particle from the axis of rotation. [ANGULAR MOTION.]

Velutinous (Ital. velluto, *velvet*). In Botany, a term applied to velvety surfaces, i.e. those having a hairy surface, which in texture resembles velvet, as in *Rochea coccinea*.

Velvet (Ital. velluto). A rich kind of stuff, used for dresses and for many other purposes. Of velvet there are properly only two kinds, that with a plain, and that with a tweeled, or, as it is also called, a Genoa ground or back. When the material is silk, it is called *velvet*; when cotton, *velveteen*. The latter is a species of *fustian*, which, under a variety of names, is largely used for men's wearing apparel.

Vena Cava. [HEART.]

Vena Portæ (Lat.). In Anatomy, the great trunk formed by the union of the veins from the abdominal organs of digestion, which trunk ramifies, after the manner of an artery, in the substance of the liver, and transmits its blood by capillaries to the hepatic veins.

Venation (Lat. vena, *a vein*). In Botany, the arrangement of veins or ribs in a leaf or other organ.

Veneer (Ger. furniren). In Architecture, a thin piece of material of a more valuable kind laid on another of a more common sort, by which the whole substance appears to be of the more valuable sort. Veneering is more usually applied to furniture than to strictly architectural purposes.

Venesection (Lat. vena, *a vein*, and seco, *I cut*). The opening of a vein with the lancet, as a means of withdrawing blood immediately from the general circulation.

Venetian School. In Painting. The distinguishing character of this school is colouring, and a consummate knowledge of chiaro-scuro. But it is not to be inferred that it is altogether wanting in still higher accomplishments: for the head of it was Titian; and in its ranks are to be found Tintoretto, Paul Veronese, Giorgione, the elder Palma, Lorenzo Lotto, and many other illustrious masters. The Venetian painters both of the *Quattrocento* period and of the *Cinquecento* were equally distinguished for their brilliant colouring, but a better understanding of chiaroscuro and the harmony of colouring has given a great superiority of effect to the works by the later masters. Of the Quattrocento painters may be mentioned especially John Bellini, Basaiti, and Cima da Conegliano. The higher effect of the later masters was accomplished in a great degree by skilful glazing—*velatura*, the veiling of one colour with another. [PAINTING.]

Venetian Talc. A kind of Talc or Steatite used for making the coloured crayons called *pastels*; and also the cosmetic called *fard*.

Veni, Sancte Spiritus (Lat. *Come, Holy Ghost*). The name given in the Roman

Church to a sequence in the office of the mass for Whit Sunday.

Venial Sin (Lat. venia, *forgiveness*). In Theology, venial sin is defined, by Roman Catholic theologians, to be a sin which weakens sanctifying grace, but does not take it away: it is not necessary, although commendable, to mention such sin in confession. Sins which take away sanctifying grace are termed *mortal*.

Venice White. A pigment consisting of carbonate of lead mixed with sulphate of baryta. *Dutch White* and *Hamburgh White* are similar mixtures.

Venire Facias (Lat. *cause to come*). In Law, a writ directing the sheriff to cause a jury to come and try a cause; now superseded by other forms of process. *Venire facias* is also the name given to the first process in an outlawry, in case of non-appearance to an indictment for misdemeanour.

Venose (Lat. venosus, *full of veins*). In Botany, a term applied to bodies having many branched veins, as in reticulated leaves.

Vent (Fr. vente). In Artillery, the hollow channel in a piece of ordnance through which the flame is communicated to the charge of powder for its ignition. All vents in the British service are two-ninths of an inch in diameter. [TUBE.]

Ventayle or Aventayle (Fr. ventail). The visor of a helmet. [HELMET.]

Venter (Lat.). In Entomology, the lower part of the abdomen.

Ventilation (Lat. ventilatio, from ventus, *wind*). This word signifies literally, *fanning* or *blowing*. In Domestic Economy, it is the art of conveying currents of fresh air through close apartments or confined places, so as to maintain the atmosphere in a state of purity.

Atmospheric air consists of three principal ingredients, nitrogen, oxygen, and carbonic acid, mixed together in the proportion by volume of four parts of nitrogen, one part of oxygen, and $\frac{1}{500}$ of carbonic acid. When the proportion of carbonic acid is increased to one per cent. air becomes unfit for respiration; and when the oxygen is withdrawn or consumed, it is rendered altogether incapable of supporting animal life or combustion. But there are operations both of nature and art continually going forward in which the oxygen of the atmosphere is consumed, and gaseous products evolved which are destructive of life. Thus, in the act of respiration, a certain portion of the oxygen contained in the air inhaled into the lungs is converted into carbonic acid, a substance which acts as a narcotic poison; and hence, in a confined apartment, air is soon rendered, by breathing alone, not merely incapable of maintaining life, but highly destructive of it, in consequence of the evolution of a deleterious gas. In like manner, oxygen is consumed, and carbonic acid evolved, in the process of combustion; and the burning of a pan of charcoal in a close room is a certain means of extinguishing life.

Although a decomposition and deterioration of air is thus continually going forward, nature has by various means provided so effectually for the restoration of the two constituent gases, that in whatever part of the world, and at whatever height in the atmosphere, air is taken, it is found when chemically examined to contain the three ingredients above mentioned, in almost exactly the same proportions. [AIR.]

Sources of Aërial Movement.—One of the most efficient means of ventilation is afforded by the action of heat. At ordinary temperatures, air suffers an expansion of about $\frac{1}{490}$ for each degree of Fahrenheit's thermometer, by which the temperature is raised; and being rendered specifically lighter in the same proportion, the pressure of the surrounding atmosphere predominates, and the heated air is forced upwards. This principle is exemplified in the action of the ordinary chimney, which may be regarded as a tube open at both ends, and placed in any position except the horizontal. The air in the lower end of the tube, being heated by the fire, rises and passes out at the upper end, while its place is supplied by the pressure of the fluid surrounding the lower opening; and the circumstances of motion are the same as if another tube, filled with air of the original temperature, were adapted to the lower end of the chimney, which is filled with heated air, so that the current is established in the same manner as in an inverted siphon, in which two columns of air of different densities, but equal altitudes, press against each other. At the lower opening of the chimney, the draught or velocity of the current is expressed by this formula,

$$v = \sqrt{[2gha(t'-t)]},$$

where v denotes the velocity in feet per second, g the accelerating force of gravity ($=32\cdot2$ feet per second), a the rate of expansion for one degree of increased temperature, t' the temperature of the heated air as it enters the chimney, and t that of the external air. It appears from this that the velocity of draught is as the square root of the height of the chimney, and the square root of the excess of temperature at the lower opening. But as the same quantity of air must be supposed to pass through every different section of the chimney in the same time, it follows that the velocity at every part must be inversely as the density, and therefore decreases from the bottom to the summit.

Warming the Air used for Ventilation.—In inhabited buildings of all kinds ventilation is necessary; but in some seasons warming is not necessary, and in tropical climates, instead of warming the entering air, expedients are sometimes employed to cool it. Nevertheless, the processes of warming and ventilating are so intimately associated that it will be expedient to consider them together.

Mr. Hood has found by his experiments that the water contained in an iron pipe 4 inches in internal diameter and $\frac{1}{4}$ inch thick, loses $\cdot321$ of a degree of heat per minute when its tempera-

ture is 125° in excess of that of the surrounding air; and as one cubic foot of water in losing 1° in temperature will heat 2,990 cubic feet of air 1° in temperature, a foot of 4-inch pipe will heat 222 cubic feet of air 1° per minute when the difference between the temperature of the air and of the pipe is 125°. One square foot of glass in a window will cool 1·279 cubic feet of air per minute as many degrees as the internal temperature of the room exceeds the external temperature. In conservatories, therefore, the quantity of air to be warmed per minute from the temperature of the external air to the temperature desired to be maintained is in round numbers 1¼ cubic foot, which gives a measure of the extent of heating surface required. The exact length of 4-inch piping necessary to heat such a structure may be determined by the following rule: Multiply 125 by the difference between the external and intended internal temperatures, and divide this product by the difference between the temperature of the pipes and the intended temperature of the apartment; finally, multiply this quotient by the number of cubic feet of air to be warmed per minute, and divide this product by 222, which will give the feet in length of 4-inch pipe necessary to produce the desired result. Thus, in a hothouse in which it is required to maintain a temperature of 75°, the external air being sometimes as low as 10°, if the cooling surface of glass be 800 square feet, then the refrigeration will be such as would cool 1,000 cubic feet of air per minute from 75° to 10°, and this refrigeration will require 292 feet of 4-inch pipe to counteract it. About 4 square feet of heating surface in a boiler exposed to the direct action of a pretty strong fire will evaporate a cubic foot of water in the hour, and will supply the heat required by 232 feet of 4-inch pipe which is required to be kept at a temperature of 140° above that of the surrounding air.

In warming apartments by steam of 212° the temperature of the pipes does not exceed 200°. But the most usual method of warming is by hot water, sometimes carried in cast-iron pipes with faucet joints, and sometimes in wrought-iron pipes, like gas pipes, with screwed joints. Cast-iron pipes, while they are being heated from 32° to 212°, expand $\frac{1}{900}$ of their length. For heating mills by steam, a pipe is usually led into every floor with a siphon pipe at the end for conducting away the condensed steam, and these pipes are set with a small declivity to cause the water to run towards the siphon at the end. This siphon is sometimes replaced by a valve so constructed as to allow of the escape of the condensed water, but to prevent that of the steam. In heating by hot water, the rapidity of the circulation will depend upon the height to which the circulating pipes rise above the boiler, and the difference in the temperature of the ascending and descending columns. Thus, if the average temperature of the pipes be 170°, the difference in the temperatures of the ascending and descending columns be 8°, and the height of the columns be 10 feet, then with the columns nearly filled the hotter will stand ·331 inch higher than the cooler, in order that the two may balance from the diminished specific gravity of the hot column; and this difference of height will give a circulating velocity of 79 feet per minute. If the height of the columns be reduced to 5 feet, the circulating velocity will become 55 feet per minute. The boiler by which the water is heated may either be an open or a close one; and the pipes may either be a closed circuit with a coil immersed in the boiler for acquiring heat, and a coil exposed to the air for imparting heat, or the refrigerating coil may project the returning pipe to the bottom of the boiler, and the transmitting pipe may rise from a point a little below the water level. A moderately sized house may thus be very effectually heated by the aid of a common washhouse boiler open at the top, or fitted only with a wooden lid. The boiler being nearly filled with water, a pipe is to be led from a point a few inches below the water surface, and coiled either at some point near the foot of the stairs, or in some other convenient situation where the air will gain ready access to it, and after being heated may ascend through the house. The descending end of the coil is then to be carried to the bottom of the boiler, and a small pump is to be applied at the highest part of the coil, to pump the coil full of water. The fire then being lighted, and the water level in the boiler, maintained by adding more water to the boiler to supply the place of that which is sucked into the pipes, the circulation will begin and will continue so long as the boiler is kept hot. But every morning when the fire is lighted, it will usually be necessary to pump out of the coil the air liberated from the water, which, however, it will only take a minute or two to do.

In discussing the proper means of ventilating houses and public buildings, there are three main points which present themselves for consideration: (1) the quantity of air necessary to be introduced; (2) the proper mode of its introduction; and (3) the arrangement by which the ventilating current may best be maintained. Peclet is of opinion that 5 cubic feet of air per minute should be introduced into a house or building for each occupant of it, whereas Reid maintains 10 cubic feet per minute to be the right quantity, and Arnot 20 cubic feet. Roscoe concludes from his examination of the air of soldiers' barracks that 20 cubic feet of air per minute are required for ventilation; and Morin found that in the theatre of the Conservatoire at Paris the amount needed was about 18 cubic feet of air per head per minute, which is also about the allowance in most of the Parisian theatres. In hospitals about twice this quantity is necessary. In good dwelling-houses, however, with lofty rooms and few occupants, 3½ cubic feet of air per minute for each person will be sufficient. A common window will allow about 8 cubic feet of air per minute to pass, and if an apartment be heated

with pipes maintained at a temperature of 200°, then, with a temperature of 10° below freezing outside, to maintain a temperature of 60° within there must be 1 square foot of pipe surface for every 6 square feet of window surface, or 120 square feet of wall, or 6 cubic feet of air per minute escaping as ventilation. A double window only lets through one-fourth of the heat that is let through by a single one; and in cold weather it will be useful to keep the blinds down, as the transmission of the heat will thus be diminished.

With regard to the proper mode of introducing air into apartments for ventilation, Morin is of opinion that in summer it should be introduced in thin sheets or threads near the ceiling, whence it would subside, and, dragging the impure air with it by friction, should be discharged through outlets nearer the floor. In common houses this may be done by opening the window a little at the top. But in barracks and other crowded buildings it is best done by means of perforations or air bricks in the walls, communicating with a triangular box or cornice running along the wall near the ceiling, with the upper inclined side covered with perforated zinc for permitting the air to flow obliquely upward against the ceiling, while the lower inclined side is formed of board without perforations. A foul-air shaft is usually carried up in the form of a chimney or funnel, proceeding from the ceiling to a height of a few feet, and terminating in inverted louvres to prevent down draughts in gusty weather. About one square inch of inlet for every 60 cubic feet of capacity of the room is the usual proportion in barracks, and one square inch of outlet in the foul-air shaft for every 60 cubic feet of space in the lower floors, or for every 55 cubic feet in the floor next above, or for every 50 cubic feet in the top floor. Besides an open fireplace to heat the rooms in winter, an inlet is provided for the admission of air behind the grate, where it is heated and escapes through an air-flue, which conducts it to an orifice near the ceiling where it is delivered into the room. In large rooms, whether barracks or hospitals, it is advisable to have many foul-air flues, or openings into a horizontal foul-air flue running through the length of the apartment, so as to collect the foul air at the spot where it is generated, and not to permit it to be all swept to one end of the room, but so to govern the eduction that all parts of the room will be pure alike. The entering air should be conducted through a small bent flue, which springs from the lower surface of the arch which covers the window and conducts to the perforated cornice already described. A considerable portion of the heat lost by transmission through the window in cold weather will thus be recovered by being communicated to the entering air. All private houses ought to have perforations in the walls which will admit air to the space behind the grate, which air, after being heated by contact with the hot iron, should be permitted to enter the room either through perforations in the upper part of the front plate of the grate, or through a hot-air flue provided for the purpose. Wherever mixing chambers can be provided for diffusing the hot among the cold air, before entering the room, such mixing will be advisable. But in other cases it will suffice to deliver both streams of air near the ceiling, where they will mix before descending to the lower part of the room. The foul-air shaft should proceed from that part of the room which is farthest removed from the inlet orifices, and its debouch should in all cases be so far removed from the points at which the air enters, as to give proper assurance that no part of the foul air will come into the room again.

The most pleasant, convenient, and economical mode of warming a dwelling-house consists in providing for the admission of the external air into the hall, where a close stove (not an open fireplace) raises its temperature to about 55° Fahr. Very moderate fires in the separate apartments will then secure sufficient warmth and thorough ventilation, if such apartments be made to derive their supply of air from the hall by means of ventilating grids near the ceiling.

One of the most necessary and neglected applications of ventilation is to the case of ships and steam vessels in tropical climates. In steam vessels the neglect of such ventilation is specially inexcusable, as it could be so easily accomplished by the aid of the furnaces. In ordinary furnaces about 300 cubic feet of air pass through the fire for every pound of coal burnt; in a steamer, therefore, of 500 nominal horse-power, working to five times the nominal or 2,500 actual horse-power, if we take the consumption of coal to be 2½ lbs. per actual horse-power there will be 6,250 lbs. of coal burnt every hour, or 104 lbs. every minute, which will require 31,200 cubic feet of air per minute. This exhausting power, by causing the furnaces to draw their air from the cabins, will afford ventilation for 624 persons at 50 cubic feet of air per head per minute—an allowance which would not be too great, considering that it is not ventilation alone, but refrigeration also, that is wanted in such a case.

Ventilator. Any machine or contrivance for promoting or regulating ventilation. The common ventilators placed in windows or in external walls serve only to retard in some degree the entrance of the current, to disperse it in different directions, and to prevent any sudden increase in the intensity of the draught. They have no power of acting so as to create a current, or keep up its intensity when it has been established, and are, as a rule, of little use.

Ventral (Lat. ventralis, from venter, *the belly*). In Anatomy, the parts or the aspect of the region of the belly: the plates of the vertebral or serous layer of the embryo that are extended towards that region are called the *ventral laminæ*.

VENTRAL. In Botany, a term used to signify that the part to which it is applied belongs to the anterior surface. Thus, a ventral suture is

the line running down the front of a carpel on the side next the axis.

Ventricle (Lat. ventriculus, dim. of venter). A term in Anatomy, applied to cavities of the brain and of the heart.

Ventricose. In Botany, a term applied to those organs which swell unequally on one side, as the corolla of many labiate and personate plants.

VENTRICOSE. In Zoology, a part is so termed when it bellies out as if filled with air.

Ventriloquist (Lat. venter, and loquor, *I speak*). One whose voice appears to come from his belly. Ventriloquists are generally supposed to have the power of making the voice appear to come from distant objects or quarters; but this is a deception, arising out of the manner in which the ventriloquist manages his voice. The art appears to consist in filling the lungs with air, and employing, during expiration, such organs of voice as can be used without the aid of the lips, or at least with as little movement of the lips, mouth, or cheeks, as is compatible with the pronunciation of certain words.

Venue (Nor. Fr. visne; Lat. vicinia, *neighbourhood*). In Law. By the original institution of trial by jury, jurors were summoned from the immediate neighbourhood where a fact happened, to try it by their own knowledge. Hence, long after the institution had been altered in character, jurors were still summoned in point of form from the parish, village, &c., until, by 4 Anne c. 16, they became summonable, as they still are, from the body of the county. The venue, therefore, was the neighbourhood named in the VENIRE FACIAS, or writ summoning the jury. In civil actions the venue is the county in which the action is to be tried, which is specified in all material allegations in the pleadings; it need not be the county in which the fact took place, except in what are called *local actions*. [PLEADING.] It can be *changed*, i.e. the trial may be directed to take place in another county, either by consent of parties, or by special order of the court or a judge, on the ground of material evidence, apprehended unfairness of trial, and the like. In criminal proceedings, the general rule is that the offence must on the face of the indictment appear to have been committed within the jurisdiction of the court before whom the prisoner is tried, but many modifications of this rule have been introduced by various statutes. (See particularly 14 & 15 Vict. c. 100.)

Venus (Lat.). In Astronomy, one of the principal planets, the second in order of distance from the sun, and the most brilliant of all the planetary bodies. From her alternate appearance in the morning and evening, Venus was called by the Greeks *Hesperus* and *Phosphorus*, the *evening* and *morning star*; sometimes also she is called the *shepherd's star*.

The mean distance of Venus from the sun is ·7233316, that of the earth being unity; her true distance is found by multiplying the old and new values of the earth's distance from the sun, viz. 95,274,000 and 91,678,000 miles, by this number. Her sidereal revolution is performed in 224·7007869 mean solar days; and her synodical period, or the interval between her successive conjunctions with the sun, is 583·920 mean solar days. The inclination of the orbit to the ecliptic was 3° 23′ 28·6″ at the commencement of the present century, and is subject to a decrease of about 0·0455″ in a year. The eccentricity of the orbit is ·00685900, half the major axis being unity; and the longitude of the ascending node at the commencement of the present century was 74° 54′ 12·9″, having a motion westward, when referred to the fixed stars, amounting to 17·6″ in a year.

The mean apparent diameter of Venus, or her apparent diameter when at her mean distance, is 16·9″; but it is subject to great variations, being only 9·5″ at the time of her superior conjunction, and at the time of the inferior conjunction sometimes so much as 62·0″. Comparing this with her mean distance, her true diameter is ·975, that of the earth being unity; and is consequently about 7,800 English miles. Her volume is therefore ·996 that of the earth. Her mass is $\frac{1}{401911}$ that of the sun.

Venus, being an inferior planet, is never seen in opposition to the sun. Her greatest elongation, or angular distance from the sun, varies from 45° to 47° 12′. According to her various positions relatively to the sun and earth, she changes her phases like the moon, appearing when she first emerges from the sun's rays and becomes visible in the morning as a fine luminous crescent, the horns of which are turned away from the sun. As the planet recedes from the sun, the breadth of the crescent increases: at the greatest elongation it becomes a semicircle; after this the breadth of the disc goes on increasing till the planet arrives at its superior conjunction, where it appears as a full orb, the illuminated side being turned towards the earth. These appearances, on account of irradiation, are not appreciable by the naked eye, but they become visible in an ordinary telescope.

Venus is supposed to revolve about an axis; and the time of rotation is stated, from observations made by Schroeter, to be 23 h. 21 m. 7·2 s., the axis of rotation being inclined to the ecliptic in an angle of about 75°. There is, however, considerable doubt as to the accuracy of these conclusions. On this subject Sir John Herschel remarks, that Venus, 'although it attains occasionally the considerable apparent diameter of 61″, which is larger than that of any other planet, is yet the most difficult of them all to define with telescopes. The intense lustre of its illuminated part dazzles the sight, and exaggerates every imperfection of the telescope; yet we see clearly that its surface is not mottled over with permanent spots like the moon: we perceive in it neither mountains nor shadows, but a uniform brightness, in which we may, indeed, fancy obscurer portions, but can seldom or

never rest fully satisfied of the fact. It is from some observations of this kind that both Venus and Mercury have been concluded to revolve on their axes in about the same time as the earth. The most natural conclusion, from the very rare appearance and want of permanence in the spots, is, that we do not see, as in the moon, the real surface of these planets, but only their atmospheres, much loaded with clouds, and which may serve to mitigate the otherwise intense glare of their sunshine.' (*Outlines of Astronomy*, p. 311.)

Venus is sometimes seen to pass over the disc of the sun, presenting a phenomenon analogous to that of a solar eclipse by the moon. This phenomenon, which is called a *transit of Venus*, can only happen when the planet is at its inferior conjunction, and, at the same time, very near one of its nodes. It is therefore a rare occurrence, but a very important one, inasmuch as it affords the best means astronomers possess of determining the sun's parallax, and consequently the dimensions of the planetary system. [PLANET.] Delambre has given a list of all the transits occurring in a period of 2,000 years. The following contains all that have happened since 1631, and that will happen before the end of the twenty-first century:—

1631, Dec. 6.	1874, Dec. 8.
1639, Dec. 4.	1882, Dec. 6.
1761, June 5.	2004, June 7.
1769, June 3.	2012, June 5.

The first transit ever seen was that of 1639, which was observed in this country by Horrox and Crabtree. The importance of the phenomenon for determining the sun's parallax was first pointed out by James Gregory in his *Optica Promota*, 1663.

VENUS. In Mythology. The name of this Latin deity is, perhaps not without reason, connected with the Sanscrit root *van*, to desire, love, or favour. Thus, in the Rig-Veda, girvanas means *loving invocations*, and yajnavanas *loving sacrifices*, and the common Sanscrit preserves *vanita* in the sense of a beloved woman. To the same root belong apparently the Anglo-Saxon *wynn*, pleasure, the German *wonne*, and the English *winsome*. The word Venus, therefore, denotes either love or favour; to the former signification belongs the Latin venustas, to the latter the verb veneror, to venerate, i.e. to seek the favour of anyone, *venia* being strictly favour or permission. Venus was probably not the oldest, and certainly not the only name, for the goddess of love in Italy, as the Oscan deity was named Herentas; but Venus herself remained little more than a name, until she was identified with the Greek APHRODITE. She is not mentioned in any of the traditions relating to the regal or early republican periods, and the festival of the Vinalia had nothing to do with her name. But when the Roman MARS was confused with the Greek Ares, the myth of the loves of Ares and Aphrodite was imported into the notion of Venus, while fresh additions were made on the strength of the Homeric hymn which described Æneas (the ancestor of Romulus, the founder of the Roman state), as a son of Anchises and Aphrodite. Her worship being once introduced, it was rapidly multiplied under that profusion of epithets which characterises the religious system of the Romans generally. Thus we find a Venus Murtea or Murcia, a name of doubtful origin; Venus Cloacina, from cluere, Gr. κλύζειν, *to wash or purify*; Venus militaris, barbata, equestris, as well as other epithets.

The introduction of Venus into the story of PSYCHE by Appuleius is a subject of greater interest for the student of comparative mythology. It has been commonly supposed that in this tale Appuleius, deriving the materials simply from his own imagination, intended to set forth allegorically the trials and sufferings of the human soul in its search after happiness and wisdom, the moral of the story agreeing with that of the well-known apologue of Prodicus, entitled the *Choice of Heracles*. An analysis of the tale will, however, show that Appuleius found all his materials made ready to his hand, and that he has rather weakened than strengthened the beauty of the myth by adapting it to the taste of a thoroughly artificial age. The story is, in short, one of the few which point to the existence of popular fairy tales during the so-called classical periods; and the incidents in the tale of Psyche are precisely those of that large class of legends of which the popular story of *Beauty and the Beast* may be taken as a typical example.

These tales are found scattered through almost the whole of the Aryan family of nations; many of them have only recently been set down in writing, and others perhaps exist still only in oral tradition. They vary, of course, in local colouring, as well as in the names employed; but the sequence of incidents is for the most part the same, and the leading ideas, as well as the turning points in the tale, are the same in all, without exception. In each case the youngest and most beautiful of three daughters is married or given up to some unsightly being or monster, or to some one whom she is led to suppose hideous and repulsive. In some instances the enchantment is ended when the human maiden feels and confesses her love for the disguised being in his unsightly shape: in the more common version, which Appuleius followed, the maiden has a lover who is marvellously beautiful, but whose beauty she has never seen. In all cases, however, there are jealous sisters or a jealous mother who insist that the lover is hideous, and incite her to look upon him while he is asleep. Following their advice, she disregards the warnings in each case given that such curiosity cannot be indulged without causing grievous disaster and distress. In each case the sleeping lover is awakened by a drop of oil or tallow from the torch or candle

in the maiden's hand, and is instantly transformed, generally into a bird who tells her that she must wander in search of him through many weary years, and do the bidding of some harsh mistress into whose power her fatal curiosity has brought her. In some versions, as in that of Appuleius, this mistress is the mother of the lost lover. Then follow the years of wandering and toil, which can be brought to an end only by the achievement of tasks, generally three in number, and all utterly beyond human powers. In these tasks the maiden is aided by brute creatures whom she has befriended in their moment of need, and who perform for her that which she could not possibly accomplish herself. The completion of the ordeal is followed by the happy union of the maiden with her lost lover.

No hypothesis of conscious or unconscious borrowing can account for the diffusion of this myth in Italy, Egypt, India, Norway, and Germany, among classes who have never possessed a written literature, and in countries between which there was in earlier times no intercommunication. The uselessness of any such hypothesis has been shown by Mr. Dasent in the Introduction to the *Popular Tales from the Norse*; but the internal evidence of the stories will probably render all other arguments superfluous for those who will take the trouble to compare them. The extent to which the myth, retaining still the essential idea, may become modified, is seen in the tale of 'The Soaring Lark' in Grimm's *Household Stories* (*Kinder- und Haus-Mährchen*). In this story the maiden knows that the being who is during the day a lion is at night a man, but no ray of light must fall upon him while he is in his human shape. At her entreaty, however, he goes to the bridal feast of her elder sister, where a single ray of light streams in upon him through a chink in a door made of unseasoned wood, and the maiden entering the room finds a dove, who says that for seven years he must fly about in the world, but that at every seventh mile he will let fall a drop of blood and a feather to guide her in her quest of him. At last this guidance fails her, and she asks the sun and moon to tell her whither the dove has gone. As in the tale of Demeter and PERSEPHONE, they are unable to tell her, but they give her a casket and an egg which one day may be of use. She then asks aid of the north wind, who bears her over the world until she rescues her lover (who has resumed his lion's shape) from a caterpillar who is an enchanted princess. But the latter, when disenchanted, seizes on the maiden's lover and bears him away. The maiden follows to the place where she hears that the wedding is to be celebrated, and then opening the casket finds a dress which glistens like the sun, and which the princess seeks to buy. But it can be given only for flesh and blood, and the maiden demands access to the bridal chamber as her recompense. During the first night her lover sleeps by force of a potion, but her voice sounds in his ears like the murmuring of the wind through the fir-trees. On the next day, learning the trick, he refuses the draught; and the maiden, availing herself of the gift bestowed by the moon, is reunited to him at last.

A closer parallel to the story of Psyche is furnished by the beautiful tale, entitled 'East o' the Sun and West o' the Moon,' in the *Popular Tales from the Norse*; and with these may be compared the tales of the 'Two Brothers,' the 'White Snake,' the 'Wood-cutter's Daughter,' the 'Water of Life,' and others, in Grimm's collection of *Household Stories*, and more especially the story of Tulisa, a tale obtained from a washerwoman at Benares, and published in the *Asiatic Journal*. This tale is, in Professor Benfey's opinion, very ancient. See also the tales in the *Pentameron* of Basil, 15, 19, 44, and Hahn's *Greek and Albanian Tales*. For a more complete analysis of the fable of Appuleius, the reader is referred to Friedläuter's *Sittengeschichte Roms*.

VENUS. In Zoology, a name applied by Linnæus to a genus of *Vermes Testacea*, including those which have a bivalve shell with the frontal margin flattened, with incumbent lips; the hinge with three teeth, all of them approximate, and the lateral ones divergent at the top.

The Bivalves thus characterised enter into the Cardiacean family of the Testaceous Acephala of Cuvier, and are subdivided into the genera *Venus* proper, Lam.; *Astarte*, Sowerby; *Cytherea*, Lam.; *Capsa*, Brug.; *Petricola*, Lam.

Venus' Bath. In Botany, *Dipsacus sylvestris*: so named from water collecting in the connate bases of the opposite leaves.

Venus' Hair-stone. A name given to the clear rock crystal, containing hair-like filaments or long acicular crystals of titanium, which is found in Madagascar, Brazil, &c.

Venus' or Cupid's Pencils. Violet Quartz enclosing small golden-brown fibres of oxide of iron, found at Bristol and other localities.

Venus Urania. A Latin adaptation of the Greek Aphrodite Urania, who was thus distinguished from Aphrodite Pandemos. For the history of the name Urania, see URANUS.

Verandah. A term of Eastern origin, applied to a light gallery external to a house, supported on pillars, and frequently enclosed in front with lattice-work.

Veratria or **Veratrine.** An alkaline principle found in the root of the *Veratrum album*, or white hellebore, and in the seeds of the *Asagræa officinalis*. It is acrid and poisonous; not easily soluble in water, readily soluble in alcohol, and less so in ether. It excites violent sneezing. It is used externally in the form of ointment, to allay the pain of neuralgia. It is represented, according to Merck, by the formula $C_{64}H_{52}N_2O_{16}$. [COLCHICUM.]

Veratric Acid. An acid contained in the seeds of *Asagræa officinalis*, formerly known

as *Veratrum Sabadilla*, hence also called *sabadillic acid*. Its formula is $C_{18}H_{10}O_8$.

Veratrum (Lat.). A genus of *Melanthaceæ*, consisting of perennial herbs, natives of the mountainous regions of Europe and North America, and having erect stalks, ovate pointed leaves, and panicles of polygamous flowers. These plants are remarkable for their acrid properties. The rootstocks of *V. album*, called White Hellebore, are collected in the Alps and Pyrenees for medicinal purposes. They are so extremely acrid that the drug is rarely employed in this country. Its effects seem to be due to the presence of *veratria*, an acrid alkaline substance found also in *Asagræa*. Gardeners make use of *V. album*, in the form of powder, to destroy caterpillars. *V. viride*, a North American species, is used for similar purposes, but seems rather less powerful. Although containing so powerful a poison, slugs and snails are particularly fond of the leaves of these plants.

Verb (Lat. verbum, *a word*). In Grammar, a part of speech which consists of an affirmation and a property or attribute affirmed. Verbs are distinguished into *transitive*, *intransitive*, and *passive*. Besides these, there is the *verb substantive*, which expresses simple affirmation abstracted from any particular property affirmed. [GRAMMAR.]

Verbascum. The Mullein genus is distinguished from its congeners in the order *Scrophulariaceæ*. It is widely dispersed over Europe, Western and Central Asia, and Northern Africa, and an immense number of species have been described, many of them probably mere varieties or hybrids. They are tall erect strong-growing mostly biennial herbs. The thick woolly leaves of *V. Thapsus*, the Great Mullein, have a mucilaginous bitterish taste, and a decoction of them is employed in domestic practice in catarrhs and diarrhœa. They are also used as emollient applications to hard tumours, and in pulmonary complaints in cattle—hence one of its popular names is Bullock's Lungwort. The ancient Greeks are said to have used the leaves as lamp-wicks, while the Romans, who called the plant *candelaria*, dipped its stalks in suet to burn at funerals. The English name, Hig-taper or High-taper, appears to allude to a similar use. This was a famous plant with the witches of old, whence it has been sometimes called *Hag-taper*.

Verbenaceæ (Verbena, one of the genera). A natural order of perigynous Exogens, consisting of trees, shrubs, or herbs, closely resembling *Labiatæ* in their tubular or campanulate calyx, in their corolla which is usually irregularly five-lobed, and in their two or four ovules enclosed in as many cells, but differing in the ovary not being lobed, and having a terminal style. They also rarely have the aromatic properties of *Labiatæ*. The species are numerous, the greater number tropical or from the temperate regions of the southern hemisphere, very few being found in Europe, Northern Asia, or North America. The typical genus, *Verbena*, furnishes one of the most beautiful and popular of our garden flowers. The remarkable virtues which the common Vervain, *Verbena officinalis*, was reputed to possess, are apparently imaginary, though Vervain has ever been held to be 'an herb of grace,' and so highly was it esteemed that people are said to have worn it about the person. Before it was gathered for this purpose, the herb was first crossed and then blessed in the words—

> 'Hallowed be thou, Vervein,
> As thou growest on the ground,' &c.

The *Aloysia citriodora* is the Lemon-scented Verbena of the gardens. The Verbena of the perfumers, so much prized for its lemon-like scent, is the lemon-grass, *Andropogon Schœnanthus*, from which the *oil of verbena* is extracted.

Verbesina (altered from Verbena). A rather extensive American genus of *Compositæ*. The Ramtil-oil plant of India was formerly referred to this genus, and is frequently found mentioned under the name *V. sativa* in modern books, though long ago separated under the name of *Guizotia oleifera*. The Mexicans use a decoction of the Capitaneja (*V. Capitaneja*) as a vulnerary, applying it to the sores caused by the saddle on the backs of horses and mules.

Verbium. A very rare metal occurring with yttrium and erbium in the minerals orthite and gadolinite.

Verdict (Lat. verum dictum). In Law, the answer of a jury given to the court concerning the matter of fact in any cause committed to their trial. A *special verdict* is a verdict not delivered generally in favour of either plaintiff or defendant, but finding and stating the facts, and referring the law arising upon them to the judgment of the court. [JURY.]

Verdigris (from Fr. verd, and gris). A blue-green pigment, originally prepared in the South of France by covering copper plates with the refuse of the grape after the expression of the juice for wine. It appears to be a mixture of the subacetates of copper, and is now largely manufactured in this country by alternating copper plates and pieces of coarse woollen cloth previously soaked in crude pyroligneous acid.

Verditer. A blue pigment, generally prepared by decomposing solution of nitrate of copper by the addition of chalk. It is a hydrated carbonate of copper.

Verdurer or **Verderor.** An officer in the royal forests, whose peculiar charge was the care of the *vert*, i.e. in forest language, the trees and underwood of the forest, all vegetation sufficient to cover a deer being included in the term, which was divided in old language into *over vert* and *nether vert*. The office of verdurer still subsists in some of the royal forests. By stat. 10 Geo. IV. c. 50 s. 100, the verdurers were to enquire into enclosures and encroachments, and impose fines on the of-

fenders; but their jurisdiction is now practically obsolete.

Verge of the Court. The compass of the queen's court, within which is bounded the jurisdiction of the lord steward of the household. It is said to be so called from the verge, or rod of office, borne by the marshal. [STEWARD.]

Vergers (Fr. verge; Lat. virga, *a rod*). Officers attached to cathedrals and collegiate churches, whose duty it is to preserve order, &c.; their name is derived from their carrying a small mace or rod tipped with silver before the clergy.

Vergette (Fr.). In Heraldry, a pallet, or small pale. A shield divided by pallets is termed *vergette*.

Verjuice (Fr. verjus). The expressed juice of unripe or green grapes. The term is applied also to a kind of vinegar made from the juice of unripe apples.

Vermeil or **Vermeille.** A jeweller's name for crimson Garnet, with a slight orange tinge. [PYROPE.]

Vermicelli (Ital.). A paste of wheat flour in the form of wormlike cylinders of various diameters; the smallest or thread-like being termed *vermicelli*, and the larger *macaroni*. It is also cut into ribands and other forms, and is then called *Italian paste*. It is made by forcing the paste through small apertures in an iron plate, which is done by a powerful screw press. The most glutinous varieties of wheat are those which yield the fittest flour for this manufacture.

Vermiculite (Lat. vermes, *a worm*). A fine scaly variety of Pyrosclerite, resembling Talc in appearance, and composed of micaceous plates cemented together by a whitish matter; it is a hydrated bisilicate of magnesia, protoxide of iron, and alumina. When heated to redness it divides, with a vermicular motion, into threads, as if it were a mass of small worms: hence the name. It is found in North America, in Vermont, and at Milbury, Massachusetts.

Vermiform (Lat. vermis, and forma, *shape*). In Anatomy, certain parts that are convoluted and shaped like a worm are so called, as e.g. a hollow process or prolongation of the intestinum cæcum; a part along the middle of the upper and under surfaces of the cerebellum.

Vermifuges (Lat. vermis, *a worm*, and fugo, *I put to flight*). Medicines used in effecting the expulsion of intestinal worms. [ANTHELMINTICS.]

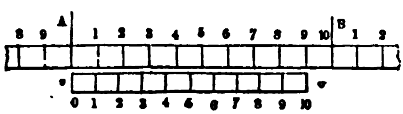
Vermilion (Fr. vermeil, Ital. vermiglione). Red sulphide of mercury. [CINNABAR; MERCURY.]

Vermin (from Lat. vermis). Quadrupeds, reptiles, worms, or insects, which are injurious to the cultivator. The number of these is great in every country, and calls into continual requisition the skill and vigilance of man to subdue them. In British agriculture the sheep and poultry are attacked by foxes, weasels, and other quadrupeds; the corn and other seeds and roots by rats and mice; and all plants, as well as seeds, by the weevil, the gnat, the turnip-fly, the Hessian-fly, the cockchafer, the wire-worm, and other insects. In gardening, almost all plants are liable to the attacks of insects, seeds to those of rats and mice, and fruits to be eaten by birds. In general, the most efficient mode to subdue insects which attack plants is to invigorate their growth as much as possible by culture, because it is found that insects thrive best on plants which are in a state of incipient disease; and the next best mode to this, is the encouragement of such natural enemies to vermin as are not themselves more injurious than the creatures they prey upon. There are some insects, such as the turnip-fly, the wheat or Hessian fly, and the aphis or green fly, which multiply very rapidly owing to the extensive propagation of the plants on which they feed; and these are the insects which are most injurious to the cultivator, because he cannot multiply their natural enemies in the same proportion as he multiplies the insects by cultivating on a large scale the plants on which they grow. The aphis he may destroy by the application of tobacco-water and other means; but he has little or no control over the turnip-fly or the wheat-fly. Happily for man, the seasons are not always alike propitious to these and other enemies to vegetation.

Vermontite. [MISPICKEL.]

Vernation (Lat. vernus, *belonging to the spring*). In Botany, the manner in which leaves are arranged within the leaf-bud.

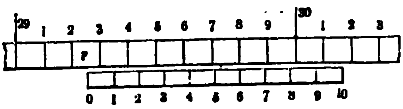
Vernier. A contrivance for measuring intervals between the divisions of graduated scales or circular instruments. The name is given from that of the inventor, Peter Vernier, who published an account of the contrivance in a work printed at Brussels in 1631. It consists of a small movable scale, sliding along the graduated scale or arc; the divisions on the one scale being to those on the other in the proportion of two numbers which differ from each other by unity. The theory of the instrument, and the manner in which it is used, may be explained as follows: Let AB $=a$ be



a distance on the scale containing n of its divisions. Let $v\,v$ be another scale equal in length to $n-1$ of the divisions on A B; and let $v\,v$ be divided into n equal parts. Since the distance AB $=a$, and contains n equal parts, each division on the scale $=\frac{a}{n}$. Hence the length of the vernier $vv=a-\frac{a}{n}$; and, as it is also divided into n equal parts, each division on the vernier $=\frac{1}{n}\left(a-\frac{a}{n}\right)=\frac{a}{n}-\frac{a}{n^2}$; and therefore the

difference between a division on the scale and one on the vernier $=\frac{a}{n^2}$. Suppose the zero of the vernier to coincide with the division marked A on the scale; then the first division on the vernier will not coincide with the first after A on the scale, but fall behind it by a quantity equal to their difference, or equal to $\frac{a}{n^2}$. In like manner, the next line on the vernier will fall behind the next on the scale by a quantity equal to twice the difference of the divisions, or equal to $\frac{2a}{n^2}$. The third on the vernier will fall behind the third on the scale by $\frac{3a}{n^2}$; and so on to the n^{th} division on the vernier, which will fall behind the n^{th} on the scale by $\frac{na}{n^2}=\frac{a}{n}$, i.e. by a whole division; and therefore the n^{th} division on the vernier coincides with the $(n-1)^{\text{th}}$ on the scale. Conceive the scale to be a scale of inches, and suppose it divided into tenths; then $a=1$ inch, $n=10$, $\frac{a}{n}=\frac{1}{10}$ of an inch, and $\frac{a}{n^2}$ (the difference between a division on the scale and on the vernier) $=\frac{1}{100}$ of an inch; so that the $\frac{1}{100}$ of an inch is exhibited on the scale, though its divisions are only to tenths.

The vernier is connected with the scale in such a way that it can be moved along it by means of a rack and pinion, a tangent screw, or some similar contrivance, and its zero be brought to coincide with any point on the scale. If, when the vernier is thus adjusted, its zero coincides exactly with a division on the scale,



the measure is read off at once; but if (as must generally happen) the zero falls between two of the divisions on the scale, then some one of the lines on the vernier will coincide, or very nearly coincide, with one of the divisions on the scale, and the distance of the zero beyond the last division on the scale behind it is expressed in hundredths by the number of the division on the vernier which is coincident with a division on the scale. Suppose, for example, the position of the vernier with respect to the scale to be as represented in the annexed figure, where the zero of the vernier is brought to coincide with a certain point p on the scale. The point p is read on the scale 29 inches, $\frac{2}{10}$, and a fraction which is to be measured by the vernier. Here the division 6 on the vernier coincides with that which is marked 8 on the scale; therefore the distance of the zero of the vernier from the last division 2 behind it on the scale is $\frac{6}{100}$ of an inch; for as 6 on the vernier coincides with 8 on the scale, the distance of 5 from 7 is $\frac{1}{100}$; of 4 from 6, $\frac{2}{100}$; of 3 from 5, $\frac{3}{100}$; of 2 from 4, $\frac{4}{100}$; of 1 from 3, $\frac{5}{100}$; and of 0 from 2, $\frac{6}{100}$. In like manner, if the vernier were pushed along till the division 8 coincided with 30 inches on the scale, then the reading of the zero point would be 29 inches $\frac{2}{10}$ and $\frac{8}{100}$. If, when the zero is brought to coincide with p, none of the divisions on the vernier coincide exactly with a division on the scale—for example, if the 5 on the vernier should be a little past the 7 on the scale, and the 6 not up to the 8—the reading would be between $\frac{5}{100}$ and $\frac{6}{100}$; but its precise amount could only be stated by estimation. If the line 5 appeared nearer 7 than 6 to 8, the distance measured would be greater than $\frac{5}{100}$, or $\frac{10}{200}$, but less than $\frac{11}{200}$; and if the line 6 appeared nearer to 8 than 5 to 7, the distance would be greater than $\frac{11}{200}$, but less than $\frac{12}{200}$ or $\frac{6}{100}$. Thus in any case the limits of the uncertainty must be confined within a distance $=\frac{1}{200}$ of an inch. In order that the coincidences may be observed with greater certainty, the divisions are usually read with a lens.

The vernier is equally applicable to circular scales, such as astronomical circles; it is then circular also, and must move concentric with the limb of the circle. Suppose the limb divided into intervals of $10'$; and let $n=10$. We have then 10 divisions on the limb $=100'$ $=a$; and the length of the vernier

$$=a-\frac{a}{n}=100'-10'=90';$$

which, divided into 10 equal parts, gives $9'$ for the length of a division on the vernier, and consequently the difference of the length of a division on the scale and on the vernier $=1'$. The arc, therefore, can be read to minutes. But the reading may be carried to much more minute quantities by increasing the length and the number of divisions on the vernier. Instead of embracing 9 intervals of $10'$ on the scale, let the vernier embrace 59 such intervals, and be divided into 60 equal parts. We have then $a=10'\times 60=600'$, $n=60$, $n^2=3{,}600$; therefore $\frac{a}{n^2}=\frac{600'}{3{,}600}=\frac{1'}{6}=10''$; i.e. the arc may be read to $10''$.

In barometers, where a considerable degree of accuracy is required, the inch is divided into 20 equal parts; the vernier is made equal in length to 24 of these, and divided into 25 equal parts. In this case we have $a=\frac{25}{20}=1{\cdot}25$ inch, $n=25$; therefore $\frac{a}{n^2}=\frac{1{\cdot}25}{625}=0{\cdot}002$; so that the vernier gives the reading to $\frac{1}{500}$ of an inch.

Instead of making the vernier equal to $n-1$ divisions of the scale, it is sometimes made equal to $n+1$ divisions, and the object will still be accomplished in precisely the same manner. For in this case the length of a division on the scale being as before, $\frac{a}{n}$, and that of a division on the vernier $\frac{1}{n}\left(a+\frac{a}{n}\right)=\frac{a}{n}+\frac{a}{n^2}$, the

difference is still $\frac{a}{n^2}$. The principle is the same in both cases.

The vernier is often called a *nonius*, but improperly, the contrivance invented by Nonius or Nunnez being on a quite different principle. [NONIUS.]

Veronica (a word made up from the Lat. vera, *true*, and icon, Gr. εἰκών, *an image* or *likeness*). A creation of Christian legend, which asserted that as Christ was led to crucifixion Veronica put a handkerchief to His face, and so obtained a true likeness. This relic is still exhibited at Rome. Alban Butler, who accepts the relic as genuine, thinks that there is not sufficient warrant for asserting that the saint who obtained it was named Veronica.

VERONICA (said to be from Arab. viroo nikoo, *beautiful remembrance*). A large genus of Scrophulariaceous plants, consisting of herbs or undershrubs, many of which are cultivated to adorn our flower borders and greenhouses. Their flowers are generally produced in close elongated spikes, and the blue colour predominates.

Verrucæ (Lat. *warts*). In Botany, the name applied to warts or sessile elevations of a glandular nature such as occur gregariously on the surface of different organs.

Verrucose (Lat. verrucosus, from verruca, *a wart*). In Botany and Zoology, when a surface presents several wart-like prominences.

Versatile (Lat. versatilis). In Botany, a term applied to bodies so placed that they swing freely, as the oscillating anthers of grasses. It is chiefly applied to anthers.

Verschaffeltia (after Ambroise Verschaffelt, a Belgian nurseryman). A genus of *Palmæ*, comprising a very handsome species, recently introduced into Europe from the island of Seychelles, and at first distinguished by the temporary name of *Regelia majestica*. The fruit is globose, drupaceous, with the scar of the stigma basilar; and the albumen is ruminated so as to form a kind of network. The species, called *V. splendida*, has a simple erect stem, clothed with spreading black needle-shaped spines; and the fronds are broad and entire, with the apex parted in two widely separate points, and the edges serrated.

Verse (Lat. versus, from verto, *I turn*). This word designates in its popular sense a line of a metrical composition, in opposition to *prose*. The division of the books of the Old and New Testaments into verses was applied in the earliest MSS. to those parts of the text in which the language of poetry is employed. The steps through which a similar division came gradually to be used throughout the whole of the biblical volumes are curious, and have been traced with great labour and particularity by Mr. W. Wright (*Cyclopædia of Biblical Literature*). Henry Stephens (Etienne Stephanus), the great French printer, has the credit of having finally established the present system, in the middle of the sixteenth century. The first English Bible in which it was adopted was the Geneva (1562), whence it passed into the Bishops' (1568), and Authorised Version (1611).

VERSE. [POETRY; RHYME; RHYTHM.]

Versed Sine of an Angle. In Trigonometry, the difference between unity and the cosine of the angle.

Version (Lat. versio, *a turning*). The use of this word in literary language is chiefly confined to the various translations of the books of the Old and New Testaments from the originals into later or modern languages. The ancient versions of the Old or New Testament, or both, known to scholars, are: the Æthiopic, Arabic, Armenian, Chaldee (Targum), Egyptian, Greek (Septuagint), Latin (Vulgate), Samaritan (Pentateuch), Syriac. The *authorised version* of the Scriptures in English was commenced in 1606, under the auspices of James I., by fifty-four scholars selected by him, and first published in 1611. (See the essays of Mr. Deutz and Mr. Plumptre, under these heads, in Smith's *Dictionary of the Bible*.)

Versor. [QUATERNIONS.]

Verst. A Russian measure of length containing 3,500 feet; about two-thirds of an English mile.

Vert (Fr.; Lat. viridis, *green*). In Heraldry, one of the colours or tinctures employed in blazonry. It is equivalent to emerald among precious stones, to Venus among planets. In engraving, it is represented by diagonal lines from the dexter to the sinister sides of the escutcheon.

VERT. [VERDURER.]

Vertebra (Lat.). This term, restricted in Anthropotomy to certain movable portions of the segments of the skeleton of the trunk, is now applied in Anatomy to the entire segment; which consists, in its typical state, of a *centrum*, *two neurapophyses*, and a *neural spine*, two *hæmapophyses* and a *hæmal spine*, and two *pleurapophyses*. The principal processes of a vertebra, which are usually exogenous, are, the *parapophyses*, the *metapophyses*, the *hypapophyses*, the *diapophyses*, the *anapophyses*, and the *zygapophyses*. The endoskeleton of the vertebrate animals consists of a series of such segments or vertebræ, some of which may support a pair of *diverging appendages*, and two pairs of such are usually developed into limbs.

Vertebræ (Lat.). In Human Anatomy, the bones of the spine. They are divided into *true* and *false*; the former constituting the upper, and the latter the lower portion of the spinal column. The true vertebræ are further divided into those of the neck, back, and loins; or the *cervical*, *dorsal*, and *lumbar* vertebræ. There are seven cervical vertebræ: the first of which supports the head, and is called the *atlas*; the second is the *dentata*: it has a tooth-like process, forming a kind of pivot upon which the head rotates. The dorsal vertebræ are twelve in number, and the lumbar vertebræ five. In the neck the spine projects forwards; it is then curved backwards in the thorax, and in the loins again projects for-

wards. There is an elastic substance between the vertebræ, admitting of a certain degree of motion; small between the individual bones, but considerable as affects the whole column. The vertebræ, and their projections or processes, afford attachments for a number of muscles and ligaments; and the spinal marrow is lodged in the bony canal formed by their several perforations.

Vertebrates (Lat. vertebratus, *having joints*). The name of a primary division of the animal kingdom, including those which have a cerebro-spinal nervous axis, protected by a bony cylinder composed of a succession of vertebræ, which are expanded into a cranium, where they enclose the enlarged anterior or upper portion of the nervous axis, called the *brain*. [Zoology.]

Vertex (Lat. literally *anything that turns*). In Astronomy, the point of the sphere directly overhead, more frequently called the *zenith*. The vertex of an angle or a cone is the point in which the sides of the angle or of the cone intersect. A vertex of a curve is any point in which a diameter meets the curve.

Vertical. Relating to vertex. *Vertical angles*, in Geometry, are the opposite angles formed by two straight lines which intersect each other. Euclid demonstrates that vertical or opposite angles are equal.

Vertical Circle. In Astronomy, a great circle of the sphere passing through the zenith and nadir. The meridian, and all azimuth circles, are vertical circles. The *prime vertical* is that particular vertical or azimuthal circle which is perpendicular to the meridian, or which passes through the eastern and western points of the horizon.

The term *vertical* is especially applied to the direction of a plumb line at any point of the earth's surface, or of the line which points to the zenith and is, therefore, perpendicular to the horizontal plane at the point.

Vertical Fire. [Fire of Artillery.]

Verticil (Lat. verticillus, *a whorl*). In Botany, a ring of organs of any kind placed round a stem upon the same plane. If the arrangement is not precisely thus, and cannot be described by a line drawn horizontally round a stem, but consists of parts either above the line or below it, the verticil is said to be broken. The verticil is commonly called a *whorl*.

Verticillate (Lat. verticillus). In Botany, a term used when several bodies form a ring round a common axis, as leaves round a stem, or the sepals, petals, and stamens round an ovary.

Vertigo (Lat.). Giddiness. This affection is a common symptom of disordered circulation in the brain, and of nervous and general debility.

Vertigo. In Zoology, a genus of marsh or land snails; so named from the abrupt twist of the volutions of the shell. Several species of this genus are British; as *Vertigo secale*, *Turtoni*, &c.

Vertumnus (Lat.). In Mythology, one of the Latin deities. From the connection of the name with the word *verto*, he was worshipped as being concerned with everything relating to change, in the seasons, merchandise, &c.

Vervain. [Verbena.]

Vesicants (Lat. vesica, *a bladder*). Substances which raise blisters upon the skin.

Vesicatorin. *Cantharidin*. The blistering principle of *Cantharides*, *Lytta*, *Mylabris*, and other blistering beetles. [Cantharides.]

Vesicle. A small blister or bladder-like tumour formed by an elevation of the cuticle, and containing a serous fluid.

Vesiculosans (Lat. vesiculosus, *full of bladders*). The name of a tribe of Tanystome Dipterous insects comprehending those which have the abdomen in the form of a bladder.

Vesper (Gr. ἕσπερος). The Latin name for the evening star, called by Hesiod a son of Astræus and Eos, and supposed to be the same as the morning star. Diodorus speaks of Hesperus as a son of Atlas, while Hyginus calls him a son of Eos and Kephalos. [Procris.] The evening star gave his name to western lands, as to Italy, which was Hesperia to the Greeks, and the name Greece has probably the same meaning. It is certain that the Hellenes did not call themselves Greeks, nor is such a people mentioned by any writer earlier than Aristotle, who speaks of the Græci as having inhabited a tract bordering on the Acheloüs, a district which would be Hesperian to those who dwell in the Eastern parts of the Hellenic land. Among the Bœotian towns mentioned in the catalogue of the second book of the *Iliad* is Graia, a name indicating possibly a western settlement during the earliest occupation of the country. The antithesis to Hesperia, or the land of the Graiæ, the kinsfolk of the Gorgons [Phorcos], is furnished by the Æthiopians, or dwellers in the glistering land, where the sun rises. But as the evening and morning star were supposed to be the same, so the Homeric Æthiopians live both in the far east and in the remotest west, where the sun goes down. (*Odyssey* i. 23.)

Vespers. One of the seven canonical hours, following nones and preceding compline [Hours], observed in modern times at two or three in the afternoon (but in Lent in the forenoon). The massacre known in history as the Sicilian Vespers was so called as having had for its signal the vesper bell of Easter Monday (March 30, 1282) at Palermo.

Vespertilionidæ (Lat. vespertilio, *a bat*). The name of a family of Cheiropterous Mammals, of which the genus *Vespertilio* is the type. It includes the insectivorous and blood-sucking species of the order.

Vespidæ (Lat. vespa, *a wasp*). A family of aculeated hymenopterous insects characterised by their geniculate antennæ, composed in the males of thirteen joints, and sometimes in this sex hooked at the extremity. Mandibles strong and dentated; clypeus large; ligula plumose or bilobed. The sting of the females and

neuters are long, powerful, and highly venomous. The larvæ of the wasp tribe are vermiform and without feet: those of the solitary species are enclosed separately in a cell, in which the mother deposits, at the same time with the egg, the bodies of insects, killed for the purpose, upon which the larva feeds.

Vesta (Lat.). One of the planetoids which circulate between the orbits of Mars and Jupiter. Vesta was discovered by Dr. Olbers of Bremen, on March 29, 1807. Its mean distance from the sun is 2·36108; the mean distance of the sun from the earth being unity; and its sidereal revolution is performed in 1325·7147 mean solar days. The orbit is inclined to the ecliptic in an angle of 7° 8′ 29″, and the eccentricity of its orbit is 0·08957. Vesta is supposed to be one of the smallest of all the celestial bodies with which we are acquainted, its volume being estimated to be only about $\frac{1}{15000}$ of that of the earth, and its surface not to exceed that of the kingdom of Spain. On account of its smallness it is, however, difficult to determine its apparent diameter with any degree of certainty.

VESTA. In Latin Mythology, a deity, identical both in name and in character with the Greek HESTIA, a word denoting *the hearth* on which the sacred fire was kept burning. She was thus inseparably connected with the PENATES, every dwelling-house being in a certain sense a temple of Vesta. Her temple in the Forum, like that at Tivoli, was round, and the lack of an image of the goddess was supplied by the perpetual fire kept up by the vestal virgins.

Vestal Virgins. This name was given to the six virgin priestesses of the goddess Vesta who had charge of her temple at Rome, and watched over the sacred fire, which was never to be suffered to go out. They had several privileges granted them; but the loss of their virginity was punished by burying the offender alive. Their institution is ascribed to Numa.

Vestibule (Lat. vestibulum). In Architecture, an area before the entrance of a house; said by some to have been so called because an altar to Vesta was placed therein.

Vestibule of the Ear. A small bony cavity of the internal ear, the opening of which into the cavity of the tympanum is closed by the small bone called the *stapes*: it is also connected with the cochlea and semicircular canals.

Vestments or Vestures, Ecclesiastical. Articles of dress or ornament worn by ministers in the celebration of divine service. The following were and are the principal known to the Western church, and many of them to the Eastern also: 1. The *vestment* properly so called, or *chasuble*, called in the Western churches *casula, planeta, pænula, amphibolum*, &c. and in the Eastern *φαινόλιον, phenolium*, was in its primitive form a perfectly round garment with an aperture in the centre for the head. When the offices were performed, it was lifted up at the sides, while the front and back remained pendent. The Greeks retain this primitive form; in the Western church it has been made to take the shape of a vesica piscis. It admitted of various materials and colours. It is of very great antiquity, being mentioned by Gregory of Tours, and appearing in a mosaic of A. D. 540. 2. The *cope* (*cappa, pallium, pluviale*, &c.) is in shape an exact semicircle with a border or orphrey on the straight side, and is fastened across the chest by a clasp called a *morse*. A hood for use was anciently attached to it; but only the form of one is now retained on it, to serve as an enrichment with embroidered work. It is also of great antiquity in the Western church. 3. The *tunicle* or *dalmatica* (called in the East *sticharion*, used by deacons), received the addition of wide sleeves as early as the fourth century. 4. The *alb* (*camisia, alba, linea*; in the East *poderis*, from reaching to the feet), a garment made of white linen, with tight sleeves, and secured round the waist by a girdle. 5. The *stole*, spoken of by the name of *orarium* as early as the council of Laodicea, A.D. 360. It is a narrow band, widened at the end to admit of an embroidered cross, and ending with a fringe. 6. The *pall* [PALLIUM], generally worn by Western metropolitans, is a circle of plain white lamb's wool with a pendant before and behind, reaching down to the feet. 7. The *rochet*, a linen garment much resembling the surplice; it is made either with or without sleeves. 8. The *chimere, simarra, cimar*, is properly a kind of cope with apertures for the arms to pass through. 9. The *pastoral staff* (*baculus pastoralis*) was spoken of in the fourth council of Toledo, in the seventh century, as used by bishops. The form of the shepherd's crook is rather later. 10. The *surplice* is a loose flowing garment of linen with expanding sleeves, worn by ecclesiastics of all ranks.

Most of these vestments are noticed in the Act of Uniformity, passed in the 2nd year of Edward VI., which regulates the habits of the English church.

For further details, see the *Directorium Anglicanum*, p. 13 &c.; Pugin, *Glossary of Ecclesiastical Ornament and Costume*.

The discussions which have been recently raised within the church of England on the question whether certain vestments are, or are not, lawfully used by ministers, have turned chiefly on the enactment of the Act of Uniformity, 1 Eliz. c. 2 s. 25, that 'such ornaments of the church and of the ministers thereof shall be retained and be in use, as were in this church of England by authority of parliament in the second year of the reign of King Edward VI. until other order shall be therein taken by the authority of the queen's majesty with the advice of her ecclesiastical commissioners or of the metropolitan.' The reference seems to be to the 'Book of the Common Prayer and Administration of the Sacraments,' ordered to be used in King Edward's Act of Uniformity, 2 & 3 Edw. VI. c. 1. But inasmuch as no certain know-

ledge can be arrived at as to the vestments really intended, and as Queen Elizabeth did not literally take any such 'order therein' as her Act of Uniformity seems to contemplate, that party in the church which is anxious to approximate as far as may be to the ceremonial of the church of Rome contends that vestments, at any time in use, and not expressly prohibited, are permissible. The question has now become complicated by ingenious and contradictory legal opinions, nor can it be solved, if its solution is deemed important, except by legislation.

Vestry (Lat. vestiarium, *a wardrobe*). The robing room attached to a church; and hence applied to designate a meeting of parishioners for parochial purposes, the bishop and priests having in former times used these rooms when they met to consult together on similar affairs.

A *general vestry* is one to which every parishioner or outdweller assessed to or paying the church rates, or scot and lot, is admissible of common right. The minister, when rector, vicar, or perpetual curate, is generally considered as entitled to be chairman of the meeting. The powers of the vestry extend to investigate and restrain the expenditure of parish funds; to determine on repairs, enlargements, ornaments, &c., of the church; and to elect certain parish officers. Several Acts of Parliament have been passed for the regulation of general vestries. (Stat. 58 Geo. III. c. 69; 59 Geo. III. c. 85; 16 & 17 Vict. c. 65, which do not apply to the metropolis. See, too, stat. 1 & 2 Wm. IV. c. 60, as to parishes in towns.)

Select vestries existed by custom in many large and populous parishes, especially in and round the metropolis. Originally these consisted of a number of householders annually elected by the ratepayers. But, by usage of long standing, these bodies were in many instances self-elected; i.e. the members of the vestry filled up by their own choice any vacancy occasioned by death or resignation.

Power has been given to parishes in which select vestries did not exist by custom to appoint such vestries, by stat. 59 Geo. III. c. 12; and in many parishes the election of vestrymen, &c. has been regulated by local Acts.

The functions of select vestries, as regards the relief of the poor, are now regulated by the Poor Law Acts.

Vesuvian. *Volcanic Garnet.* The name given by Werner to the IDOCRASE of Haüy, after the locality, Vesuvius, where it was first noticed in ejected blocks, associated with Mica, Hornblende, &c. It is of a hair-brown or olive-green colour.

Vesuvian Garnet. A name for LEUCITE, originating in the trapezohedral form of the crystals, which are similar to those of Garnet.

Vetch (Lat. vicia, Ital. veccia). The name given to a family of leguminous plants with herbaceous stems, which often support themselves on surrounding objects by means of the tendrils with which their leaves are terminated. The common Vetch or Tare is extensively cultivated in Europe, and furnishes an excellent fodder for milch cows and working stock, &c.

Veteran (Lat. veteranus, from vetus, *old*). Among the Romans, a soldier who had passed the legal age of military service was termed *veteranus*.

Vetiver. [VITTIE VAYR.]

Veto (Lat. *I forbid*). In Politics, the power enjoyed by a branch of the legislature, which cannot of itself originate or modify a law, to reject the propositions of the other branch or branches. In the Polish diet, every noble who was an independent member could prevent any resolution from passing by his simple dissent (expressed in the words, 'Nie pozwalam,' *I do not permit*). This privilege, termed the *liberum veto*, was the fertile source of disorders and anarchy in that country. In most constitutional monarchies the king has an absolute veto; in some it is only suspensive. Thus, in Norway, if three successive storthings (assemblies) repeat the same resolution, it becomes law against the will of the king. The president of the United States may return a bill, with his reasons for dissenting from it, to the house in which it originated; but if both houses pass it afterwards by a majority of two-thirds in each, it is not in his power again to reject it.

VETO. An Act passed by the General Assembly of the Church of Scotland, known by the name of the Veto Act. Lay-patronage has never been cordially recognised on the part of the people of Scotland. On the final establishment of Presbytery as the national church, in 1690, patronage was vested in the elders and heritors (landowners) of a parish. In 1711 (10 Anne c. 12. s. 4) that law was annulled, and patronage was transferred as a civil right to individuals as an accessory of land, or as a separate estate; and those patronages which had of old belonged to the pope, or to monasteries, or to archbishops, bishops, and chapters, were vested in the crown. The Act of Queen Anne was never universally acceptable in Scotland. Two dissenting denominations (the United Associate Synod, and the Relief) owed their origin to the indiscreet exercise of lay-patronage; and though patrons were generally disposed, particularly within the last twenty years, to show due deference to the feelings of the people, yet hostility to this mode of nominating clergymen having gained greater force, the General Assembly, in 1834, passed the Veto Act, whereby, if a majority of the male heads of families, in full communion with the church, appear before the presbytery and dissent, or lodge dissents at the meeting for *moderating in a call*, the presentee was to be rejected. Those entitled to dissent are ascertained from a roll annually made up. The Veto Act was first passed as an interim Act; but having received the sanction of the majority of presbyteries, it was enacted into a standing law of the church by the General Assembly of 1835. (Hill's *Practice of the Judicatories of the Church*, p. 83.)

Against the provisions of this Act, the minority of the Assembly recorded, both in 1834 and 1835, their solemn protest, on the ground that these provisions were not merely wrong in themselves, but that they were likely, on the first occasion on which a patron or presentee should determine to enforce his rights, to lead to a collision between the ecclesiastical and civil courts. The issue was raised in 1835 in an action brought against the presbytery of Auchterarder for rejecting Mr. Young, who had been presented to the living by the earl of Kinnoull. In giving judgment in this action, the court of session (March 8, 1838) held that the presbytery had acted illegally, and to the hurt and prejudice of the pursuers, and in particular contrary to the provisions of the statute of 10 Anne.

This decision of the court of session was appealed from by the defenders to the House of Lords, which affirmed the judgment in question (May 3, 1839) without the alteration of a single word.

Meanwhile the dominant party of the church, resolving not to obey the judgment of the court of session, though confirmed by the higher court to which they themselves had appealed, refused to induct Mr. Young as minister of Auchterarder. They regarded the parish as still vacant, and nominated a clergyman of their own sentiments to the parochial charge, quoad spiritualia, leaving the temporalities untouched.

This conflict was followed by others of a like kind in the presbyteries of Strathbogie and Garioch. In the latter, a majority inducted the presentee (Mr. Middleton) to the parish of Culsalmond, although he been served with a veto. The ecclesiastical courts promptly interfered; but interdicts against their authority were obtained: and the case having been carried to the House of Lords, a decision was given in favour of the presentee, thus declaring that the General Assembly had no power to pass the *veto act*, and that all proceedings under it were null and void. Indignant at this judgment, the leaders of the dominant party in the Assembly determined to secede from the church, and on the first day (May 18, 1843) of the meeting of the General Assembly, the members of that body who were in favour of the *veto*, having given in a written protest, constituted themselves a body to be denominated the FREE CHURCH OF SCOTLAND.

Vexillarii (Lat.). Veteran troops in the Roman army, who, having served out their time, were retained in service, and fought under a standard of their own (vexillum).

Vexillary (Lat. vexillarius). In Botany, that form of æstivation in which one piece is much larger than the others, and is folded over them, as in papilionaceous flowers.

Vexillum (Lat. *a standard*). In Botany, the standard or fifth petal placed at the back of a papilionaceous corolla.

Via Lactea. [MILKY WAY.]

Viaduct (Lat. via, *a way*, and duco, *I lead*). A bridge for carrying a road or railway across a valley at such a height as to maintain the general level of the line. As a stream of water runs in the bottom of most valleys, most viaducts have also to cross a stream of greater or less breadth; hence the definitions of a *bridge* and a *viaduct* are not very different. [BRIDGE; TUBULAR BRIDGE.]

Viaducts, like bridges, are formed of stone, brick, timber, cast iron and wrought iron. For important bridges, and viaducts of every kind, iron is now the material commonly preferred.

Iron bridges, of rude construction, but great antiquity, are to be found in Thibet and China. But the first iron bridge constructed in England is that of one arch, over the Severn, near Colebrook Dale, which was designed by Mr. Pritchard, about 1773, and completed in 1779. In this bridge five arched ribs of cast iron support perpendicular spandril pieces, which carry the roadway, and these ribs, which are nearly semicircular, have a span of 100 feet. Sunderland bridge, over the Wear, also of one arch, was the next iron bridge constructed, and was designed by Mr. Rowland Burdon in 1792. This bridge consists of 6 segmental ribs of 200 feet span, and 30 feet rise. Each rib is 5 feet deep, and consists of 105 separate pieces. Buildas bridge, over the Severn, also of one arch, by Telford, followed in 1816. It has a span of 130 feet with a rise of 27 feet. Boston bridge, by Rennie, has a span of 100 feet with a rise of 4 feet; and Southwark bridge, by Rennie, in 1818, has three arches, the centre one of 240 feet span and the side ones of 210 feet span. Telford's design for crossing the Thames by a single cast-iron arch was not carried out.

The rise and progress of the railway system led to the construction of railway bridges of many different kinds. In the earlier iron bridges the material was used in compression alone, as if it were a superior kind of stone. But the girder principle, which had been successfully introduced by Boulton and Watt for supporting great weights in mills and manufactories, was adopted in many railway bridges, sometimes in the form of simple cast-iron girders and sometimes trussed with wrought iron.

The failure, however, of one of these trussed girders in the case of a bridge upon this principle carried across the Dee, near Chester, discredited the system, and girders of wrought iron then began to be introduced. Such girders when applied to large spans naturally expanded into two systems; one the tubular system, as exemplified in the Menai bridge, and the other the lattice system, which last is now very generally employed in the case of deep girders suited for large spans. One very creditable example of this species of bridge is that which carries the London, Chatham, and Dover Railway across the Thames at Blackfriars, and in

which the girders rest on clustered columns of cast iron set upon strong cylindrical bases of stone.

The Crumlin viaduct on the Newport, Abergavenny, and Hereford Railway, in Wales, is formed of cast and wrought iron. The total height from the bed of the stream to the rails is 200 feet; distance from centre to centre of piers, 150 feet; total length of viaduct, 1,200 feet. The piers are formed of clusters of cast-iron columns, placed in stages. Each column is 17 feet long, by 1 foot diameter, and from 1 inch to $\frac{7}{8}$ of an inch thick. The number of columns in each stage is 14, and they are arranged in four rows of three each, with one at each side of each pier, which gives it a salient angular outline. The width between the columns at the base of each pier measures 13 feet 6 inches in every direction, except between the centre rows, where it measures 6 feet throughout the height. At the top of the piers the width between the columns is reduced to 9 feet. Measuring from the centres of the columns, the dimensions of the pier at the base are 60 feet by 27 feet, and at the top 30 feet by 18 feet, making a diminution of 30 feet in one direction and 9 feet in the other; to effect which all the columns except the central ones are made to lean correspondingly. The columns are trussed sideways to one another, and are fitted endways to one another with socket joints, a projection of half an inch being left on the top of each, which fits into a corresponding recess in the base of the one above it; and the surfaces, which are truly turned, are held together by four bolts at each joining passing through lugs. The foundations, which are of strong masonry, are generally carried down to the rock. The girders are made on Warren's principle, and consist of a stout beam above, a tie below and diagonal filling. The girders are 150 feet long and 14 feet 6 inches deep. The dimensions of the top tubular beam or girder are $14\frac{1}{2}$ inches by 9 inches, the sides being of inch plates, and the top and bottom of $\frac{1}{2}$-inch plates. The ties at the bottom of the girder consist of four wrought-iron bars of 6 inches by $\frac{5}{8}$ of an inch. There are 18 diagonals to each girder, and towards the centre they are strengthened by plates. This viaduct, which was opened in 1857, contains 1,300 tons of wrought iron, and 1,250 tons of cast. The high-level bridge at Newcastle is constructed of cast iron, and is formed with two platforms, of which the upper carries the railway, and the lower the common road. It consists of 6 spans of the average width of 125 feet, and the height is $108\frac{1}{2}$ feet. The piers measure 50 feet by 16 feet, and are lightened by arches.

The Chepstow and Saltash bridges are, in a certain sense, suspension bridges, in which a platform, carrying the roadway, is supported by ties and chains. But the towers, instead of being tied back by chains, are strutted asunder from one another by great wrought-iron tubes. The Boyne bridge on the Dublin and Belfast Railway is formed on the lattice-girder principle, the main span being 264 feet, and the two side ones 137 feet.

Suspension bridges have not usually been deemed suitable for railway purposes, inasmuch as the existence of a load at any one spot was supposed to be likely to throw the bridge out of shape, by sinking it at that place, and raising it at some other. This derangement, however, it is obvious, would be prevented by a properly stiffened roadway, which would also prevent the roadway from being put into waves in high winds; and Mr. Roebling, in 1848, threw a suspension railway bridge over the St. Lawrence just below the falls of Niagara, the breadth of the chasm being 800 feet, and the height of the bridge above the water 245 feet. This bridge consists of wire cables supporting a rectangular tube 20 feet deep by 26 feet wide, or rather two floors 18 feet apart, the upper carrying the railway, the lower a roadway for ordinary traffic. By bracketing out from the rocks, the free length of the tube is reduced to 700 feet, and it is then suspended from towers 82 feet apart from centre to centre by 4 wire cables of 10-inch section, and each containing 3,640 separate wires. When a train weighing 300 tons passes over the bridge, the deflection is said to be only 10 inches. If the published accounts are to be believed, this suspension bridge, or viaduct, cost only 100*l*. per foot forward. The total span is 822 feet.

The following are some examples of ordinary viaducts of various kinds:—

The Victoria bridge across the St. Lawrence at Montreal, constructed on the same principle as the Menai tube [Tubular Bridge], is made with a single tube 6,592 feet long in 25 spans, the central one of 330 feet, and the other 24 of 242 feet each. The masonry of the piers cost 114*l*. per foot of the bridge, and the ironwork 57*l*. The cost of the masonry of the piers has been greatly increased by the necessity of making them of great strength, and with sharp underlying spurs pointing against the stream at each pier, to resist and break up the masses of ice which are brought down the river in the spring when a thaw begins.

The Soane bridge on the line of the East Indian Railway connecting Calcutta with Benares, is of a length not much inferior to that of the Victoria bridge across the St. Lawrence. During a part of the year the Soane is a small river, but in the rains it rises forty or fifty feet, and spreads over a wide bed. The bridge consists of lattice girders resting on piers, and the piers rest on wells, which are built up with solid masonry, and constitute a great pile or pillar of brickwork, capable of sustaining a very heavy load. Bridges similar to that over the Soane have been built over the Jumna at Allahabad and Delhi.

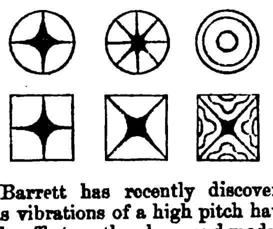
Mr. Fowler's viaduct across the Severn, at Oldbury Sands, is 4,131 yards long, and the principal opening for the navigation is of 600 feet span, and 95 feet high.

Viaticum (Lat. *supplies for a journey*). In the Church of Rome, the Eucharist when administered to dying persons is so called. It is given with extreme unction, but only to those who are in full possession of their faculties.

Vibration (Lat. vibratio, from vibrare, *to shake*). In Mechanics, the reciprocating motion of a body, as of a pendulum, a musical chord, or elastic plate. The term *oscillation* is, however, more frequently used to denote a slow reciprocating motion, as that of the pendulum, which is produced by the action of gravity on the whole mass of the body; while *vibration* is generally confined to a motion with quick reciprocations, as that of a sonorous body, and which proceeds from the reciprocal action of the molecules of the body on each other when their state of equilibrium has been disturbed.

VIBRATION. In Music, that regular reciprocal motion of a body, which, suspended or stretched between two fixed points, swings or shakes to and fro. The vibrations of chords are the source of the different tones emitted. [SOUND.]

Vibrations of Elastic Plates. When thrown into vibration transverse to their length, elastic plates divide themselves into an even number of vibrating segments, each segment moving in a direction *opposite* to that of the adjacent part. It follows that the points of separation between two parts participate neither in the motion of the one nor of the other, and consequently remain at rest. In the case of thin elastic plates, the continuity of these points forms lines of repose, or *nodal lines*, the forms and positions of which are detected by placing the vibrating plate in a horizontal position, and strewing a small quantity of fine sand over its upper surface. This method of investigating the vibration of plates was discovered by Chladni, who, by the arrangement of the sand, obtained a great variety of figures which bear his name. A few of the simpler figures observed when a square and round plate are thrown into vibration, by means of a violin-bow, are here shown.



Mr. Barrett has recently discovered that sonorous vibrations of a high pitch have a remarkable effect on the shape and mode of combustion of a tall and voluminous flame of coal-gas. By means of a properly shaped burner, a smoky flame about eighteen inches long is obtained, which at the sound of a whistle shrinks down to half its height, spreads out laterally into a fish-tail appearance, and yields a largely increased amount of light, so long as the sound is sustained. By adjusting the shape of the burner or increasing the pressure of the gas, the flame may be rendered wonderfully sensitive to certain sounds, so that at the lowest whisper or the slightest noise the flame can be made to shrink. The term *sensitive flames* has been applied to jets of gas in this state. The cause of their susceptibility to the influence of sound appears to be this: the sonorous pulses throw the pipe which conveys the gas to the burner into vibration, and the flow of gas, being thereby urged to the centre of the tube and confined within narrower limits, issues from the burner with an increased velocity so long as the sound continues. Now a sensitive flame is one which on the slightest mechanical increase in the velocity, or (what comes to the same thing) the pressure, of the gas, will shrink and take precisely the appearance which it has when influenced by sound. In the same way a fish-tail flame can be made to flare either by increasing the pressure on the gas or by a musical note, the latter having been discovered in America by Dr. Leconte some time ago. Since their discovery in 1866, the subject of sensitive flames has been examined by Dr. Tyndall (*Phil. Mag.* February 1867), and a résumé of the whole matter is given in an article in the *Popular Science Review* for April 1867.

Vibrations of Musical Chords. [SOUND.]

Vibrionidæ. The name of a tribe of Animalcules, commonly known as microscopic eels, of which the genus *Vibrio* is the type. One of the species of this genus of Animalcules is parasitic upon wheat: they form a cottony mass in the interior of the grain, which, when the latter is ground, will not pass through the cloth, but remains behind in the bran. When full-grown, the *Vibrio tritici*, as this species is termed, attains a quarter of an inch in length; but the young are of such microscopic minuteness, that Mr. Bauer, the naturalist, has calculated that 50,000 of them might be contained in one grain of wheat. The disease thus occasioned is commonly termed *ear-cockles*. Scalding water has been mentioned as the most obvious remedy.

Vibrissæ (Lat.). In Mammalogy, the stiff long-pointed bristles which grow from the upper lip and other parts of the head. In Ornithology, the term is also applied to hairs which stand forward like feelers; or which in some birds, as the fly-catcher, point both upwards and downwards from the upper and under sides of the mouth; or which spread out on each side like a comb from the upper sides of the mouth only, as in the goatsucker, when they are termed *vibrissæ pectinatæ*.

Viburnum (Lat.: the ancients made use of the word *viburna* to signify any pliant branched plant, that could be used for tying or binding). An extensive genus of *Caprifoliaceæ*, consisting of shrubs natives of Europe, Asia, and North America, but not found in tropical regions. *V. Lantana*, commonly known

by the name of the Wayfaring-tree, is a large shrub generally found in hedges or woods. Its leaves and berries are astringent; the latter are used in Switzerland in the manufacture of ink, while the former yield with alum a yellow dye. The wood is white and hard, and useful for turnery purposes. The rind of the root is used to make birdlime. *V. Opulus*, the Gueldres Rose, furnishes in one of its varieties, having the inflorescence sterile, the well-known ornamental shrub called the Snowball tree. *V. Tinus*, the Common Laurustinus, a native of the South of Europe, which in Corsica forms large woods, is a valuable shrub, from its dense evergreen foliage, and its cheerful flowers, produced very early in the year.

Vicar (Lat. vicarius). A clergyman who has the care of a parish as incumbent, in the place of (vice) a lay or collegiate rector. [Tithes.]

A vicar in the church of England is the principal ecclesiastical person (*parson*) of his parish; the word *rector*, where there is a vicar, denoting only the owner of the rectorial tithes, and not the acting clergyman. The corresponding term in French (*vicaire*) denotes an assistant minister, whom we designate a *curate*, the French *curé* being the principal clergyman of a parish (in which sense the word *curate* is used in the English Liturgy), so that the terms *vicar* or *vicaire*, and *curate* or *curé*, have exactly changed places in the two languages.

Vicar Apostolic. In the Ecclesiastical language of the court of Rome, a person in episcopal orders, holding from the pope authority to exercise his office in certain defined countries and districts wherein there is no organised Roman Catholic establishment. Thus England was under vicars apostolic until of late years, and Scotland is so still. Very frequently the vicar has the titular dignity of bishop of some see formerly Christian and now suppressed, technically called *in partibus infidelium*. The *vicars apostolic* are under the direction of the Congregation de Propagandâ Fide. [Propaganda.]

Vicars of the Empire. In the German constitution, princes who had the right of representing the emperor in case of absence or interregnum. The king of the Romans, whenever there was one, was perpetual vicar. If there were none, the office was divided into two: the elector of Saxony exercised the vicariate in the two Saxon circles; the electors palatine, and of Bavaria, alternately in the remainder of the empire. They administered revenues, presented to benefices, received feudal homage, &c.

Vice-admiral. The grade of *flag-officer* next below an admiral. He ranks with a lieutenant-general in the army.

Vice-chamberlain. An officer of the royal household immediately under the lord chamberlain.

Vice-chancellor. The great increase of the business of the Court of Chancery has from time to time rendered necessary the appointment of assistant judges. One vice-chancellor was accordingly appointed in 1813, and two more were added in 1841 after the abolition of the equitable jurisdiction of the Court of Exchequer. Each vice-chancellor sits in a separate court, and takes a share of the general business of chancery; his decisions are subject to an appeal to the lord chancellor or the lords justices of appeal (who were in like manner appointed in 1851 to assist the lord chancellor). The judge of the local court of chancery of the duchy of Lancaster is also termed a *vice-chancellor*, as being the legal deputy of the chancellor of the duchy, an officer whose functions are political only. The chancellors of the universities also, though nominally the principal functionaries of those corporations, act for the most part only through vice-chancellors.

Vicegerent (Lat. vicem gerens, *holding the place of any one*). Any officer acting as deputy or lieutenant of another.

Viceroy or **Vice-king.** A title often applied in common usage to any officer representing the supreme authority in a dependency; e.g. the lord-lieutenant of Ireland. But it has seldom been officially given, except to the governors of certain dependencies of the old Spanish monarchy; such as Naples, Peru, and Mexico, each of whom bore the pompous title of *alter ego* of the sovereign.

Vicia (Lat. *a vetch*). A large genus of papilionaceous *Leguminosæ*, whose species are distributed throughout the temperate regions of the globe. They are weak plants, generally climbing, with pinnate leaves, which terminate in tendrils. *V. sativa* is the Tare or Vetch of our farmers, and is extensively grown as fodder for cattle. It is distinguished from most of the species growing in this country, either wild or cultivated, by its sessile solitary rarely twin flowers, and by its smooth seeds. The common Bean is sometimes included in this genus under the name of *Vicia Faba*. [Faba.]

Victim. [Sacrifice.]

Victoria (after Queen Victoria). This truly royal genus of *Nymphæaceæ* consists of an aquatic species of the highest interest from its beauty and curious conformation. It has thick fleshy rootstocks, sending up numerous long cylindrical leafstalks, traversed by air canals, and armed with stout conical prickles. The blade of the leaf is peltate, circular in outline, and when fully developed is from six to twelve feet in diameter, its margin uniformly turned upwards to the depth of two or three inches, giving the appearance of a large shallow tray, while the lower surface is traversed by very prominent nerves radiating from the centre to the margin of the leaf, and connected one with another by smaller nerves running transversely, so that the whole under surface is divided into a number of irregularly quadrangular compartments or open cells, by which the enormous leaves are well adapted to float on the water. The flowers when fully expanded have the

outer petals bent downwards, while the central rose-coloured ones, with the stamens, remain erect; and thus a noble appearance is presented, as of a central rose-coloured crown supported by a series of pure white and most gracefully curved petals. The fruit when ripe is a sort of globular berry, thickly beset with formidable prickles. These noble plants inhabit the tranquil rivers of South America, and especially the tributaries of the Amazon. The Spaniards call the plant Water Maize, as they collect the seeds and eat them roasted.

Victoria Cross. A British naval and military decoration. It consists of a Maltese cross of bronze, with the royal crest in the centre, and underneath an escroll bearing the inscription, 'For valour;' it is worn with a blue riband for the navy, a red riband for the army. It is ordained that neither rank, nor long service, nor wounds, nor any circumstance or condition whatsoever, save the merit of conspicuous bravery, shall be held to establish a sufficient claim to the honour. The royal warrant instituting the order bears date Jan. 29, 1856.

Victory (Lat. Victoria). In Roman Mythology, a goddess, called by Varro the daughter of Heaven and Earth. Her altar was preserved in the curia or senate house of Rome; and its destruction was the subject of one of the latest contests between Christians and Pagans. (Beugnot, *Destr. du Paganisme en Occident*, i. 410, 430; *Mém. de l'Acad. des Inscr.* vol. xviii. 21.)

Vicuna. [AUCHENIA; MELIDÆ.]

Vidame. In French Feudal Jurisprudence, originally an officer who represented the bishop, as the viscount did the court (vice-dominus). In process of time, these dignitaries erected their offices into fiefs, and became feudal nobles, such as the vidame of Chartres, Rheims, &c.; continuing to take their titles from the seat of the bishop whom they represented, although the lands held by virtue of their fiefs might be situated elsewhere.

Videlicet (Lat. contracted from videre licet, *it may be seen, it is clear*). In Law. In pleading, it is usual to state any allegation which forms part of the facts set out, but which it is not intended to prove with precision, with the words *to wit* preceding it, as where anything is alleged to have taken place heretofore, *to wit* on such a day. This is termed *putting a videlicet* or *scilicet*.

Videttes (Fr.). Sentries placed on outposts and elevated points, so as to be able to observe the approach or movements of an enemy.

Vierzonite. A kind of yellow ochre, found at Vierzon, Dépt. du Cher, in France.

View (Fr. vue). In Law, the inspection by a jury previously to trial of the place, on or with regard to which the matter in controversy has arisen.

Vigil (Lat. vigilia, *a watching*). In Ecclesiastical usage, the evening before a feast day is so termed. Originally celebrated by meeting together at night (as they are still on some occasions in the Eastern churches), the vigils preserve the memory of the nocturnal assemblies of Christians in times of persecution.

Vigna (after Dominic Vigna, a commentator on Theophrastus). A genus of *Leguminosæ*, founded upon plants originally referred to *Phaseolus* and *Dolichos*. *Vigna* is distinguished by its pods being nearly cylindrical, instead of flattened as in *Dolichos*, and by their being constricted between the seeds, which are separated from each other by thin spurious partitions. The species are dispersed over the tropics of both hemispheres, most numerously, however, on the American continent. They are herbs, with twining or prostrate annual stems, trifoliate leaves, and axillary flowers. [PHASEOLUS.]

V. sinensis is very extensively cultivated in the East, particularly in India, where its pulse is called Chowlee, and forms, in conjunction with rice, a considerable part of the food of the Hindus. The Chinese, who call the plant Tow-Cok, cook and eat the green pods as we do kidney beans. When ripe the pods are frequently as much as a yard long, and contain about twenty seeds, of variable colour and variously marked. A variety of it (*Dolichos melanopthalmus* of some authors) is cultivated in Italy and other parts of Southern Europe under the name of Fagiolo del Occhio.

Vignette (Fr.). A small ornamental engraving without complete background or bounding line, used in printing for the illustration or decoration of a page of any work.

Vignite. A mineral found in France, at Vignes, in the Moselle. It is probably a mixture of magnetic iron-ore, with carbonate and phosphate of iron.

Vikings. The Norse name of the piratical leaders, known to us as the Sea-Kings, whose assaults began in the ninth century.

Villa (Lat.). In Roman Antiquities, originally any country dwelling. Many descriptions of ancient villas are found in the pages of classical writers; but the two most complete (besides those contained in the work of Vitruvius) are the accounts given by Pliny the younger of his Laurentine and Tuscan residences (*Epist.* ii. 17, v. 6). To these may be added the pleasing, though over-ornamented poetical delineation of Statius, *Silvæ*, lib. 3, describing a magnificent residence overlooking the bay of Naples. The most important parts of an ordinary villa were the *porticoes*, one or more, along the front or sides of the mansion; the *triclinium* or dining room: the wings forming suites of apartments, commonly called, in the time of Pliny, *diætæ*; the *baths*, with their appurtenances, the *hypocausta* or vaulted heating rooms, *apodyteria* or dressing rooms, rooms for exercise (*sphæristeria*), &c. Adjacent to the main portico was generally the XYSTUS.

Village or **Vill** (Lat. villa, properly a *country house*). In English Legal phraseology,

this word appears formerly to have been nearly synonymous with *town*, denoting an assemblage of houses with or without adjacent land; but it is now applied usually to the principal body of contiguous dwelling-houses in a country parish. In countries where there are peasants attached to the glebe, or possessing distinct rights and obligations from other subjects, a village is properly a place inhabited by peasants only. From the Latin villa was derived the French ville, *city*, originally signifying any residence; and thence a collection of houses which gradually grew around a principal residence. Thus, especially in Normandy, *ville* is a common termination to the names of places, like *ton* or *by* in England; and consequently, also, of family names. The English *town* furnishes a parallel instance of the alteration of the meaning of a word produced by an increase of population, our original *towns* having been single residences or hamlets; and in Scotland at this day, a house with its appurtenances in rural districts is sometimes called *the town*.

Village System. In infant or rude agricultural communities, a peculiar form of communism is frequently recognised. The land is supposed to belong to all alike, and is portioned out in plots or strips for the labour of the several occupiers. The produce is stored in a common barn, and distributed according to the necessities of the inhabitants by the headman, who is also responsible for taxes and rents payable from the village. Relics of such a system are still to be recognised in the *lands* still or till lately found in the common fields throughout some of the midland and southern counties. The clan system of Wales and the Highlands, and the Irish gavelkind, with its attendant custom of tanistry, were modifications of the village system, which was common in Russia up to comparatively late times, and still exists in many parts of India.

Villarsite. A hydrated silicate of magnesia, resembling Serpentine in hardness and translucence, and in texture and colour very like certain kinds of phosphate of lime from Arendal. It occurs in small crystalline veins, and in brilliant translucent rhombic octahedrons; also massive and granular—of a yellowish-green or greyish-yellow colour; at Traversella in Piedmont in veins of magnetic iron-ore. Named after M. Villars.

Villein (Low Lat. villanus). According to the ancient law books, such as Glanville and Bracton, the villein of the early middle ages was absolutely dependent on his lord, was possessed of no chattels which the lord could not seize, and could be sold with his family into slavery at the lord's discretion, the only protection accorded to him being that of a remedy against atrocious personal injuries. It is further stated that villeins were *regardant* and *in gross*: the former being attached to the soil (ascripti glebæ), from which they could not be removed, though their services and chattels could be sold and enforced; the latter attached to the person of the lord, and therefore saleable as slaves. This distinction has been disputed by Mr. Hallam, who inclines to the view that the condition of villeins was exceedingly depressed.

Historical evidence, derived from contemporary documents, presents us, however, with a very different picture. The villein, in the thirteenth century at least, is in possession of land, which he holds permanently at labour or money rents, and which descends to his representatives on payment of a slight fine. A tax called a *heriot*, and generally in the form of his *best chattel*, is leviable from his estate on his decease, instead of all his chattels lying at the discretion of the lord. He is prohibited from quitting the manor, except a yearly rent or a round sum be paid, the rent or the charge for total emancipation being very small. He cannot send his son into the church or to the university without paying a similar fine, for to take even the lesser orders involved emancipation. He cannot marry his daughters without paying a fine, known as *mercheta*, *culage* or *jambage*. But he has his legal remedy in county courts against any one but his lord, being liable to him before the freeholders of the manor only, who were not likely to strengthen his lord's hands. He serves on juries, and has his vote for the knights of the shire up to the famous election statute of Henry VI., by which the franchise was limited to the forty-shilling freeholder.

If the state of the villein described by Glanville (*De Legibus Angliæ*) had ever any literal existence, a great change must have been effected during the long and obscure reign of Henry III. It is certain that the condition of villeins became better and better during the fourteenth and fifteenth centuries, and that they had become copyholders long before the Reformation. The last enfranchisement is found in the reign of Elizabeth, when a fine was paid, not we may be sure for social privileges, or legal equality, but for some larger rights over land. The latest plea of villenage alleged as a defence to an action was made in the reign of James I., but the court unanimously decided that servitude was unknown to the English law, and that the plea was bad.

For further information as to the condition of the peasantry during the thirteenth and fourteenth centuries, see Prof. Rogers' work on *Agriculture and Prices in England*.

Villenage (Low Lat. villenagium). The state of a villein, or of lands and tenements held by a villein.

Villi (Lat. villus, *the long hair of animals*). In Anatomy, the name given to minute vascular processes covering, in the proportion of about twenty-five to every square line, the surface (hence called *villous*) of the mucous membrane of the small intestine, and giving it a velvety or fleecy appearance. They promote the absorption of chyle from the completely digested food. Similar minute vascular processes of

the chorion and other membranes are called *villi*.

Villose (Lat. villosus, from villus). In Botany and Zoology, when a part is covered with soft flexible hairs thickly set.

Vinagrillo. A South American name for *Oxalis Acetosella*, used as a salad plant. The same term is also applied in Chili to dried cakes of pounded oxalis leaves, which are infused in water to make an acid drink.

Vinalia (Lat. from vinum, *wine*). According to Varro and Ovid, a festival in ancient Rome. There were two vinalia: the first in April, sacred to Venus; the second in August, to Jupiter. The latter was considered as the beginning of the vintage season, before which new wine was not permitted to be conveyed into Rome.

Vinatico. A coarse mahogany obtained in Madeira from *Persea indica*. It is one of the shipbuilding woods recognised at Lloyd's.

Vincetoxicum (a word coined from Lat. vinco, *to conquer*, and toxicum, *poison*). A genus of *Asclepiadaceæ*, the species of which were formerly referred to *Asclepias* and *Cynanchum*; most of them are natives of the Old World, and chiefly of Western and Central Asia, though a few are European. The root of *V. officinale*, or Swallow-wort, which is the common North European species, possesses drastic and emetic properties, and was formerly in some repute as a medicine, being employed in scrofula and skin-diseases, and also, particularly in Germany, as an antidote to poisons, whence it has been named Tame-poison. When fresh, it has a disagreeable odour, and an acrid bitter taste.

Vinculum (Lat. *a bond* or *tie*). In Algebra, a mark or character which connects several letters or quantities, and indicates that they are to be treated as a single quantity. Vieta first used the bar or line over the quantities for a vinculum, thus, $a \times \overline{b+c}$; meaning that the quantity a is to be multiplied by the sum of the quantities b and c. This manner of connecting quantities was generally used by the early English writers on algebra; but it is now more common to make use of the parenthesis, which is a much more convenient mode of notation, especially when the expression is somewhat long. Thus, instead of writing $a \times \overline{b+c}$, or $\sqrt{\overline{x^2 - 2xy + y^2}}$, it is more usual to write $a\ (b+c)$, $\sqrt{(x^2+2xy+y^2)}$. The parenthesis, which has generally been used by foreign mathematicians, is said by Hutton to have been first used as a vinculum by Albert Girard.

Vine (Fr. vigne, Lat. vinea). In Horticulture, the name of the Grape Vine, the fruit of which is in universal demand, either fresh, or dried as raisins. Its fermented juice forms Wine. [Vineyard; Vitis.]

The word *vine*, in Botany is often employed in a general sense to designate any stem which trails along the ground without rooting, or entangles itself with other plants, to which it adheres by means of its tendrils or by twining; as the cucumber and the hop.

Vine Mildew. The name applied to a white mould, to which of late years the vine has been very much subject. This mould makes its appearance on the leaves and young bunches of grapes, and produces either complete abortion in the fruit, or dwarf ill-shaped juiceless cracking berries; or where a little pulp has been formed, rapidly reduces the whole into a state of decomposition. The mould was named by Mr. Berkeley *Oidium Tuckeri*. Subsequent observations have confirmed a suspicion, which was before entertained, that the *Oidia* of this group are merely a peculiar condition of different species of *Erysiphe*; and it is generally allowed that such is the case with the vine mildew itself, though it has never been observed to make any further advance than the production of those peculiar cysts, known under the name of *pycnidia*, which accompany the true fruit of *Erysiphe*. The disease has spread in every direction, and many remedies have been proposed, among which the application of sublimed sulphur has been, when properly and perseveringly applied at a sufficiently early stage, almost uniformly efficacious. [Oidium.]

Vinegar (Fr. vinaigre, Lat. vinum acre, *sour wine*). This term is applied to various modifications of the acetic acid. The simplest mode of obtaining vinegar is to excite a second or acetous fermentation in wine: in this case oxygen is absorbed, a variable proportion of carbonic acid is generally evolved, and the alcohol of the wine passes into acetic acid. Very good vinegar is also made from strong beer, or from a wort or infusion of malt prepared for the purpose, or from a decoction of common raisins, or from a mixture of about 1 part of brandy with 8 of water and some sugar and yeast. The acetic fermentation is accomplished either in casks, or by allowing the alcoholic liquid to trickle slowly over shavings or twigs, a current of air passing in the opposite direction.

When vinegar is distilled, various impurities which it contains remain in the still, and the liquid which passes over is the acetic acid, nearly pure, but largely diluted with water. In this state it is usually called *distilled vinegar*, and is used chiefly in pharmacy. But though a considerable quantity of vinegar is made in wine countries by the first-mentioned process, and here and elsewhere by the second, in which malt is employed, yet for all the purposes of the arts and manufactures, as well as for domestic consumption, the market is chiefly supplied from another source, which is the destructive distillation of wood. It has long been known that when certain kinds of dry wood (especially beech and such woods as are not resinous), instead of being burnt in the open air, are converted into charcoal in close vessels, so as, in fact, to be submitted to destructive distillation, the vapours which pass off yield, when condensed, a large quantity of tar, and of very acid water. The latter is, in fact, an impure vinegar, i.e. it owes its acidity to acetic acid, which is formed during the pro-

cess out of the carbon, hydrogen, and oxygen of the wood, which elements are also those of acetic acid, and not in very different proportions. When this impure acetic acid is freed from the tar and empyreumatic oils with which it is mixed, it is called *crude pyroligneous acid.* To convert it into pure acetic acid, i.e. to separate from it the empyreumatic products with which it is intimately combined, is a somewhat circuitous process, of which the following is an outline: It is first distilled, by which *pyroxylic spirit* and *oil of tar* first pass over, and these are followed by a quantity of impure or rough acetic acid. This rough acid, which is used by dyers and calico-printers, and by makers of sugar of lead, is saturated with powdered slaked lime, and being filtered, yields a solution of impure acetate of lime, which is evaporated to dryness, and which, distilled with dilute sulphuric acid, yields a purer acetic acid than the former, but which still has a burnt and disagreeable flavour; it is therefore again saturated by lime, and this liquid acetate of lime is mixed with a solution of sulphate of soda, which, acting by double decomposition, yields a precipitate of sulphate of lime, and acetate of soda remains in solution. The latter salt is procured by evaporation, and purified by torrefaction and crystallisation. The vinegar makers, who purchase it, decompose it in retorts or proper stills, by means of sulphuric acid, by which a very pure and strong acetic acid passes over, sulphate of soda remaining in the retort. The acetic acid thus obtained, which is in its most concentrated state, is extremely acrid, sour, and pungent, and is often called *radical vinegar*, or, when perfumed, *aromatic vinegar*; it is also occasionally termed *glacial* acetic acid, from its property of congealing at a low temperature, and remaining frozen at temperatures below 50°. In this state it is a compound of 1 atom of real acetic acid = 51, and 1 of water = 9; the real or anhydrous acid, as it exists in the dry acetates, being composed of—

	Atoms	Equiv.	Per cent.
Carbon	4	24	47·06
Hydrogen	3	3	5·88
Oxygen	3	24	47·06
		51	100·00

proportions which are equivalent to 4 atoms of carbon and 3 of water. When this strong acetic acid is diluted with water and slightly coloured, it forms a very pure and excellent substitute for common vinegar, and is cheaper than acid of the same strength prepared in any other way.

The combinations of acetic acid with various bases are called *acetates*. The acetates of lead, copper, iron, and alumina, are chiefly employed in dyeing and calico-printing; the acetates of ammonia and of potash, which, as well as acetate of lead, are used in medicine; and the acetates of lime and of soda are employed in the preparation of strong acetic acid. The acetates are recognised by their solubility in water, and by the fumes of acetic acid which they evolve when acted upon by sulphuric acid. The specific gravity of the strongest liquid acetic acid is 10629; that of good malt vinegar is 10200; and that of distilled vinegar about 10023. The strength or value of vinegar, and of acetic acid, can be learnt only by its saturating power.

The manufacture of vinegar is chiefly confined to England, the quantity produced in Scotland and Ireland not amounting on the annual average to more than 100,000 gallons. The quantity of vinegar manufactured in England is over 3,000,000 gallons annually.

Vinegar Plant. A peculiar state of the mycelium of *Penicillium glaucum.* During the process of acetous fermentation of liquids, a coat of greater or less thickness, consisting of many layers separable the one from the other, is formed on the surface. This under the microscope is found to consist of interlaced delicate branched threads, which, if placed in circumstances favourable to their developement, give rise to a crop of *Penicillium glaucum,* a universally distributed mould. If a portion of this coat is placed in a solution of sugar and water, kept in a proper temperature, the whole is converted into vinegar far more rapidly than it would be without the presence of the fungous mass. It is therefore called the Vinegar Plant, and is much used in the manufacture of vinegar. The mode in which the Vinegar Plant operates on the solution is supposed to be similar to the action of the Yeast Plant.

Vineyard. A plantation of Grape Vines cultivated for the purpose of making wine. Vineyards at present are chiefly confined to the warmer parts of the Continent, but they were formerly to be met with in Britain, more particularly in the neighbourhood of religious establishments.

Among the last vineyards of which we have any account, are one at Haffield, near Ledbury, which belonged to the celebrated Jacob Tonson; one at Bury St. Edmunds; one in the Isle of Wight; and another at Pain's Hill, in Surrey. The ground chosen in all these cases was a sloping surface of dry gravelly or chalky soil, with a southern aspect; and the vines were planted in rows at four feet apart every way, and trained to short stakes about four feet high. Every year the shoots were cut down to within a foot of the ground, and not more than three shoots were allowed to be matured by each plant. Each shoot produced two or three bunches of grapes, and the shoots were shortened in the course of the summer so as never to reach higher than the stakes, to which they were tied with rushes previously cut and dried for the purpose, or with twigs of willow. The kinds of grapes grown were chiefly the Burgundy or large Black Cluster, and the small Black Cluster or Miller grape, so called from the white mealy appearance of the leaves. In fine seasons a tolerably good wine was produced.

On the Continent, the vineyards which produce

the best wine are invariably found on dry soils, more or less calcareous; and the most celebrated are on the dry sunny sides of granitic or calcareous hills, with the surface formed into terraces, like the steps of stairs on a large scale; each step or terrace being supported on the lower side by a stone wall, to which the vines planted at the base of the wall are sometimes attached, not by nails, as wall-trees are in Britain, but by hooked sticks driven into the interstices between the stones, such walls being for the most part built without mortar. In France and the South of Germany, vines are seldom allowed to grow higher than four feet; and they are cut down every year, after the crop has been gathered and the leaves dropped, to within one or two feet of the ground. In the neighbourhood of Stuttgard, and between that city and Heidelberg, where the sides of the hills are covered with vineyards, the shoots are not cut down before winter; but those of each stool or plant are bent down to the ground, where they are tied together with a straw band, and retained in that position by laying a stone on the bundle. This is for the purpose of preserving the vines from the extreme cold of winter; the shoots, when so laid prostrate, being soon covered with snow. In spring, the shoots are raised up again, pruned, and tied to stakes. In the north of Italy, and chiefly in the plains of Lombardy, the vineyards are managed much as in France; but in Tuscany, the Papal States, and Naples, the vineyards are interspersed with mulberry-trees, which are kept pollarded; and to these the vines are attached, partly by ties of willow and partly by their tendrils, and they produce bunches of grapes to the height of six or eight feet from the ground. Sometimes the shoots are trained to elms, mulberry-trees, or poplars, in which case they produce grapes to a much greater height.

Vingt-un (Fr.). A popular round game at cards. It depends on the number of pips in the cards dealt to each player; in reckoning which, the ace counts either one or eleven at pleasure, the court cards ten each, and the others according to the number of their pips. The object is to obtain the highest number, not exceeding *twenty-one*, whence the name.

Vinous Fermentation. The change which takes place in saccharine solutions in the presence of yeast. It consists in the splitting up of sugar into two atoms of alcohol and four of carbonic acid. [FERMENTATION.]

Viola (Ital.). A musical instrument of the same form and with the same number of strings as a VIOLIN, and, like it, played with a bow, but larger, and extending a fifth lower in compass. The English call it the *tenor violin*.

Violaceæ (Viola, one of the genera). A natural order of hypogynous Exogens, consisting of herbs or shrubs, of which between two and three hundred species are known, dispersed over nearly all parts of the globe. They have usually alternate and simple leaves furnished with stipules, and axillary flowers, either solitary, or in cymes, racemes, or panicles. They have the one-celled free ovary with parietal placentas (usually three) of *Bixaceæ* and their allies, but are distinguished by their stamens being almost always five in number, with very short filaments and comparatively large anthers, erect and often connate in a ring round the pistil—their connective often very broad, and produced into an appendage at the top, with the cells opening inside the ring. The flowers, when irregular, are often large and showy; and the capsule in the greater number of genera opens in three very elastic valves.

Violan. A mineral of a dark violet-blue colour found at St. Marcel, in Piedmont.

Violet (Lat. viola). The name of a well-known wayside flower, the *Viola odorata* of botanists. The odorous emanations of Violets, like those of some other flowers, are said by Pereira to have occasionally proved dangerous. Taken internally, the syrup acts as a laxative, while the root is emetic, and might even be employed as a substitute for ipecacuanha.

Violin (Lat. fides; Ger. fiedel; Dutch vedele; Old High Ger. fidula; Mod. Lat. vitula; Prov. viula; Ital. viola, and hence the dim. violino: Wedgwood, *English Etymology*, s.v. 'Fiddle'). A musical instrument, commonly called a *fiddle*, mounted with four strings, and played with a bow. It consists of three parts —the *neck*, the *table*, and the *sounding-board*; at the side are two apertures in the shape of *S s*. On it is a bridge, which bears the strings up from the belly, over which they pass from one extremity, called the *tail-piece*, to the other near the head, where they are received by turning pins, which tighten or loosen them at pleasure.

The violin is the most perfect of solo instruments, on account of its fine tone, its great capability of execution, and, still more, of expression, in which latter respect it has no parallel.

The best violins were those made at Cremona, in Italy, more than a century ago, and which still bear a high value.

The violin tribe of instruments constitutes the main element of every concert orchestra; there are four varieties generally used, viz. the *violin*, the *viola*, the *violoncello*, and the *double bass*.

Violine. An emetic principle contained in the root of the *Viola odorata*, or common violet.

Violoncello (Ital.). In Music, a bass violin with four strings.

Violone (Ital.). In Music, a large bass violin, commonly called a *double bass*. The Italian form of the instrument has three strings, the German four.

Viper (Lat. vipera, perhaps a contraction of vivipar; from vivus, *alive*, and pario, *I bring forth*). The common name of a genus of venomous serpents which produce living young, and have a head broader than the neck, and no pits behind the nostrils. The true vipers (*Vipera*) are distinguished by the head being covered with scales, like those on the back, and by the nostrils being very large. The horned viper of

North Africa and the puff adder of South Africa belong to this group. The adders (*Berus*) have the head covered with granular scales, with larger ones intermixed in some species, and have the nostrils of moderate size. The black adder and the common adder (*Berus chersea*), which are the only indigenous venomous reptiles of Great Britain, are examples of this group.

Virgate. [YARD.]

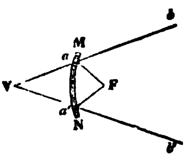
Virgilian Husbandry. [AGRICULTURE.]

Virginal. A musical stringed and keyed instrument of the harpsichord species, used in the sixteenth century. A book of exercises for the virginal, written for Queen Elizabeth, is still extant.

Virgo (Lat. *the virgin*). In Astronomy, one of the twelve zodiacal constellations, or signs, being the sixth in order, beginning with Aries. Virgo is usually represented with an ear of corn in her hand, and is hence called *Signum Cereris*. The sun enters this sign about the 22nd of August. The constellation Virgo contains one bright star of the first magnitude, called *Spica Virginis*.

Virola. Aublet, in his work on the plants of Guiana, established this genus upon one of the American Nutmegs, named by him *V. sebifera*; but modern botanists regard it and its allies as forming one of the sections of the large genus *Myristica*, consisting of large trees confined to tropical South America. *V. sebifera*, which forms a tree sixty feet high, is common in the forests of Guiana and North Brazil, and is found as far north as Panama. A solid oil or fat is obtained by macerating the seeds in hot water, and this is used in Guiana for making candles. An acrid red juice, employed medicinally by the Brazilians, exudes from wounds made in the bark.

Virtual Focus. In Optics, the point from which rays, having been rendered divergent by reflexion or refraction, appear to issue. Thus, let M N be a section of a metallic speculum, F a radiating point, F a, F a' rays falling on the speculum at a and a', and reflected into the directions $a\,b$ and $a'\,b'$; then the point V, in the concourse of the straight lines $a\,b$ and $a'\,b'$, is called the *virtual focus* of the reflected rays. [REFLEXION.]



Virtual Velocity. In Mechanics, the velocity which any point of a body in equilibrium would actually acquire during the first instant of its motion if that equilibrium were disturbed.

The general principles on which the laws of equilibrium in machines are established may be reduced to three; viz. the principle of the *lever*, the principle of the *composition of forces*, and the principle of *virtual velocities*. The last consists in this, that two forces are in equilibrium when they are in the inverse ratio of the virtual velocities of the points to which they are applied, estimated in the direction in which the forces respectively act. The principle is thus enunciated generally by Lagrange (*Mécanique Analytique*, p. 22):—

'If any system of bodies or material points, urged each by any forces whatever, be in equilibrium, and there be given to the system any small motion, by virtue of which each point describes an indefinitely small space, which space will represent the virtual velocity of the point; then the algebraical sum of the forces multiplied each by the space which the point to which it is applied describes in the direction of that force, will always vanish, regarding as positive the small spaces described in the direction of the forces, and as negative those described in the opposite direction.'

Galileo was the first to observe the above properties of virtual velocities in machines; John Bernoulli, however, first recognised the principle in all its breadth, and Varignon and several others verified it in almost all branches of statics. (Varignon, *Nouvelle Mécanique*, Paris 1725.) Lagrange, in his *Mécanique Analytique*, makes it the foundation of all mechanics, and deduces from it a uniform method of forming the equations of equilibrium and of motion for all possible systems of bodies. Fourier has demonstrated the principle from the property of the lever (*Jour. de l'École Polytech.* cahier 5); but Poinsot, in his admirable memoir (appended to his *Eléments de Statique*) on the equilibrium and on the motion of systems of bodies, has given perhaps the most complete analysis and demonstration of the principle.

Virtue. [ETHICS.]

Vis (Lat. *force* or *power*). In Mechanics, this word is synonymous with *force*. The term is used chiefly by the older writers, and is applied by them to divers kinds of forces or powers. Thus, *vis acceleratrix*, accelerating force; *vis inertiæ*, resistance; *vis motrix*, moving force, &c. *Vis mortua* and *vis viva* are terms which were used by Leibnitz and his followers; the former signifying a pressure, and the latter the force of a body in motion estimated by the distance to which the body goes. About the beginning of the last century, a keen dispute arose among mathematicians with respect to the manner in which the forces indicated by those terms ought to be estimated. It began with a prize essay by John Bernoulli on the *Investigation of the Laws of the Communication of Motion*, and was carried on for many years with great asperity. The question was, whether the force of a moving body is proportional to the square of the velocity, or to the velocity simply. No controversy (says Playfair) was ever carried on by more illustrious disputants: Maclaurin, Stirling, Desaguiliers, Jurin, Clarke, Mairan, were all engaged on the one side; and on the opposite were Bernoulli, Herman, Poleni, S'Gravesande, and Muschenbroek. The dispute was taken up as a point of national honour. Germany, Holland, and Italy declared for the *vis viva*; England stood firm for the old doctrine; and France was divided between the two opinions. ('Dissertation on the Progress

of Math. and Phys. Science,' *Ency. Brit.*) The difference in this case, as in most other disputes of a similar kind, arose from the parties not understanding each other. When the effect of a body in motion is measured by the distance to which it goes, before being brought to rest by a constant resistance, the effect is proportional to the square of the velocity; if measured by the time that elapses before the motion is destroyed by a resistance of uniform intensity, it is as the velocity simply. Both measures may be considered as correct, and they are not inconsistent when rightly understood. (Playfair's *Nat. Phil.* vol. i. p. 56.) The *vis viva*, considered as a power residing in a moving body, is now frequently called *kinetic* or *actual energy*. [FORCE; POTENTIAL ENERGY.]

Viscera (Lat.). The contents of the three great cavities of the body: the brain, e.g. is the viscus of the cranium, the heart one of the viscera of the thorax, and the stomach one of the abdominal viscera. The term is usually restricted to the organs of the thorax and abdomen; for the myelon is as much entitled to be called a viscus of the spinal canal, as the encephalon a viscus of the cranium. The hæmal arches of the cranial vertebræ have been called *visceral* in the embryo, and their interspaces the *visceral clefts*.

Viscin (Lat. viscum, *mistletoe*). A glutinous constituent of mistletoe, of certain berries, and of the middle bark of the holly,

Viscount. A title of honour; in its original signification, the delegate of a count (*vice-comes*), and applied to governors of towns and districts under the authority of that officer. In England, the appellation of *vice-comes*, or *viscounte*, in Norman French, was long used to designate the sheriff of a county (the vicegerent of the earl) before it became a title of peerage. It is the most modern of English honours in the latter sense; and was first conferred by letters patent on John Lord Beaumont, and the heirs male of his body, by Henry VI. in 1440. A viscount ranks between earl and baron.

Viscum (Lat.; Gr. ἰξός, *the mistletoe*). A genus of *Loranthaceæ*, of which *V. album*, the Mistletoe, is the only species to which any considerable interest attaches. This is a parasitical shrub, whose root, or what corresponds to a root, is firmly embedded in the substance of the tree on which it grows. The mode of attachment to the nourishing plant has been made the subject of an elaborate paper by Dr. John Harley, in the *Transactions of the Linnæan Society* (xxiv. p. 175). The roots of the mistletoe come in contact especially with the new wood inside the bark, where the descending sap is richest and most abundant, and are prolonged inwards in a direction parallel to that of the medullary rays. The cellular systems of the two plants thus come into contact, but no direct communication takes place between their vessels. As growth goes on, and annual rings of wood are added to the stock, similar rings are formed in the mistletoe, and so the woody layers of the two plants become coincident. The parasite slowly but surely involves the destruction of the branch upon which it grows.

The apple is the tree on which the Mistletoe grows most abundantly, and the orchards in Herefordshire are greatly infested with the parasite, which, however, has a value of its own, for it appears that upwards of one hundred tons of mistletoe are annually forwarded to London and other large towns from that county alone, for Christmas decorations. Next in frequency to the apple the mistletoe prefers the poplars, though it is not found on the Lombardy Poplar. It also infests hawthorns, limes, maples, and the mountain-ash. It has been found on the Cedar of Lebanon and on the larch, but rarely upon the oak. Undoubted instances of the latter have, however, been recently recorded—one at Eastnor Park, near Ledbury, Herefordshire, and another at Frampton-on-Severn, Gloucestershire. The magnificence of the oak on the one hand, and the rarity of the mistletoe on this tree on the other, are probable reasons for the greater reverence which was paid to the parasite when found on this tree.

Some botanists have proposed to separate *Viscum* from the *Loranthaceæ*, and to make it the type of a natural order, *Viscaceæ*.

Vishnu. In the Brahmanic Mythology, the god who with Brahma and Siva forms the Hindu Trimourttee. But this position is the growth of a later age. In the earliest Vedic literature, there are no indications of a Triad, the creative, preserving, and destroying power; 'and Vishnu, although named, has nothing in common with the Vishnu of the Romans; no allusion occurs to his avataras: his manifestation as Krishna, the favourite divinity of the lower classes, for some centuries at least, does not appear.' (Prof. H. H. Wilson in *Edinburgh Review*, Oct. 1860, p. 382.) By later writers he is regarded as a god who in his three strides is manifested in a threefold form, as Agin on earth, as Indra or Vayu in the atmosphere, and as the sun in heaven; but by some these three strides are interpreted as the rising, the culmination, and the setting of the sun. The place of Vishnu in the Vedas is examined at length by Dr. Muir, *Sanskrit Texts*, pt. iv. ch. ii. sec. 2.

Visible (Lat. visibilis, *that can be seen*). Objects are visible when they emit or reflect a sufficient quantity of light to make a sensible impression on the retina of the eye. According to Newton, colour is the proper object of sight; the visibility of an object must therefore depend on its transmitting to the eye rays of a different colour from those which proceed from the surrounding objects.

Vision (Lat. visio). In Optics, the faculty of seeing. Philosophers have disputed much respecting the means of vision, and its seat in the eye. The Platonists and Stoics held vision to be effected by the emission of rays out of the eyes. The Epicureans supposed vision to be performed by the emanation of images or corporeal species from objects

to the eye; and the Peripatetics differed in opinion from the Epicureans by supposing the species received by the eye to be incorporeal. Modern philosophers agree in referring the cause of vision to the impressions of light on the eye. [LIGHT.] In what manner the eye, or the particular part of it affected by the light, conveys to the brain the impression received from the luminous rays, is a question which philosophy has not yet solved.

Seat of Vision.—The retina of the eye, on which an inverted image of external objects is formed, is now generally regarded as the seat of vision. This opinion was long ago brought into doubt by the accidental discovery of Mariotte, that the base of the optic nerve is insensible to the rays of light, and consequently incapable of conveying to the brain the impression of vision. But this fact has since been explained by the discovery that the middle of the base of the optic nerve is occupied by an artery—the *arteria centralis retinæ*. This explanation has been confirmed by the experience of pathologists, who have observed cases in which the choroid coat, which is immediately below the retina, and all the vascular system of the eye, have remained sound, and yet blindness has ensued solely from an affection of the retina. On the other hand, vision, though disturbed, is not extinguished by any affection of the arteries, veins, or their combination with the pigment of the choroid, so long as the optic nerve and retina are sound.

Vision, Beatific. In Theology. The doctors of the church distinguish three manners of seeing or knowing God, which they call: (1) *Abstractive vision*; i. e. through the consideration of His attributes. (2) *Beatific* or *intuitive vision*; that which the faithful enjoy in heaven. (1 Cor. xiii. 12.) (3) The third kind of vision, or *comprehension*, is that which belongs only to God, who alone can know Himself as He is.

Visitation (Lat. visitatio). A festival of the Western Church, in honour of the visit of the Virgin Mary to Elizabeth. It is said to have been first instituted among the Franciscans by Saint Bonaventure, general of that order. It is celebrated on the 2nd of July.

VISITATION. In Ecclesiastical Law, the inspection by the bishop of the several parishes in his diocese; or by an archbishop of the dioceses in his province. By the ancient canon law, visitations were to be held once a year, and by the personal repairing of the ordinary to each parish; but the modern practice, which appears to have come gradually into use, owing to the extent of dioceses, is to summon the clergy from several parts to one convenient place. The times of episcopal visitations are now usually fixed in this country about Easter and Michaelmas. By Can. 60 of the English Church, such visitations for the purpose of confirmation must be triennial at least. The care of the ancient parochial institutions has by degrees devolved on the archdeacons, who hold periodical visitations for that purpose. They are bound to see that the offices of the church are duly administered; to keep account of the ornaments, vestments, &c. appertaining to the churches; to examine into the state of repair of parsonages, churchyards, &c.; and to receive presentments of excesses committed by ecclesiastical persons. Ecclesiastical corporations, such as conventual bodies, had usually their special visitors appointed by the founder; as is the case at present with colleges in our universities, hospitals, &c.

Visitation, Heraldic. These visitations seem to have been first instituted by King Henry V. in England; the purpose being to compel those who assumed coat armour to prove their right to do so before commissioners appointed by the crown. These visitations were usually held by the royal heralds entitled Clarencieux and Norroy (kings-at-arms), in different places within their respective provinces, once in every thirty years or thereabouts. The earliest of which the record remains in the library of the College of Arms is that of certain counties in 1528. The latest was held under a commission issued by James II. in 1686. These records are still referred to as of importance in establishing the claims of families to honours founded on pedigrees.

Vismia (after M. de Visme, of Lisbon). A genus of *Hypericaceæ*, chiefly found in the tropics of America, and consisting of trees or shrubs, with four-sided branches, opposite often glandular dotted entire leaves, and terminal panicles or cymes of yellow or greenish flowers. The yellow resinous juice common to the order exists in greater abundance in the plants belonging to this genus than in any of its congeners, and possesses more powerful purgative properties, resembling in that respect, and likewise in its appearance, the gamboge of the Old World—so much so, indeed, that that collected from *V. guianensis*, a species found in Guiana, Brazil, Surinam and Mexico, is called American Gamboge. Other species, however, such as the *V. sessiliflora* and *V. cayennensis* of Guiana, and the *V. micrantha* and *V. longifolia* of Brazil, also yield a similar resin, to which the name American Gamboge is equally applicable.

Visor or **Vizard** (Fr. visière, from Lat. video). A movable defence for the face, attached to the helmet in the middle ages. It generally turned on side pivots, sometimes on hinges at the forehead. It was worn in battle, unless the helm was put on over the bassinet, in which case the visor was removed.

Visual Angle. In Optics, the angle under which an object is seen, or the angle formed at the eye by the rays of light coming from the extremities of the object. *Visual rays* are the lines of light coming from an object to the eye.

Vitaceæ (Vitis, one of the genera). A natural order of hypogynous Exogens, nearly allied in character to *Celastraceæ* and *Rhamnaceæ*, but at once distinguished from the former by their stamens being opposite the petals, and from the latter by their valvate petals, and from both by their habit. They are mostly

tall climbers remarkable for the anomalous structure of their wood. Besides the great genus *Vitis*, which is now made to include all the species of *Cissus* and *Ampelopsis*, whether natives of the New or of the Old World, the order comprises only the small genus *Pterisanthes*, with a remarkable flat flower-stalk, and the slightly anomalous *Leea*, both confined to the Old World.

Vital Vessels. A name given by Schultz to certain vessels ramifying in all directions in plants, especially near the surface, and conveying latex, which that physiologist calls a vital fluid. The milk-vessels of spurges are vital vessels.

Vitellicle (Lat. vitellus, *yolk*, literally *a small calf*, as dim. of vitulus). The bag which is developed around the food-yolk, or that part of the yolk which has not been converted into the germ-mass and embryo. It is chiefly formed by a developement of the inner layer of the germinal membrane. The constricted part at which it is continued into the wall of the intestinal canal is called the *vitelline duct*. In man and mammalia the vitellicle is called the *umbilical vesicle*.

Vitellin. The albumen of the yolk of eggs.

Vitellus (Lat. *the yolk of an egg*). In Botany, the sac of the amnios in a thickened state, and forming a case, within which lies the embryo.

Vitiligo (Lat. vitulus, *a calf*). A disease of the skin, giving it a white appearance somewhat resembling that of calves.

Vitis (Lat. *a vine*). The genus *Vitis*, composed of a considerable number of species, including the well-known Grape-Vine, which is its most familiar and important representative, has a wide geographical range, but is principally found in the northern hemisphere, the majority of its species being natives of tropical and temperate Asia as far north as Japan, and also of North America. All the species are climbers, furnished with tendrils opposite the leaves, as in the Grape-Vine, the leaves of some being simple, and either undivided or variously lobed, and those of others compound. Their small greenish flowers are disposed in panicles set opposite the leaves, the Eastern species having complete flowers, and the Western usually incomplete ones, the two sexes very frequently on different plants.

The Grape-Vine is a native of the southern shores of the Caspian Sea and of Armenia. Associated with the fig, it follows the coast of the Black Sea, through Pontus, Mingrelia, and Colchis, and it has been found in the Crimea. From Asia, on the authority of Humboldt, the vine passed into Greece, and thence into Sicily. It was early carried into France by the Phocæans, when those Ionian colonists fled from the power of Cyrus, and founded the city of Marseilles, about 540 B.C. From Greece or from Sicily it could be easily introduced into Italy. The Romans planted it on the banks of the Rhine, and even, it is said, in Britain. Domitian restricted the cultivation of the vine, wishing rather to encourage that of grain; but in A.D. 278, permission to plant the vine was given by the emperor Probus. Being free from restriction, its cultivation throughout the provinces, including that of Britain, would of course extend. Vineyards are mentioned in the earliest Saxon charters, and these must have existed previously; for the combating invaders could neither have had the time, nor probably the skill, to make them. The monks in A.D. 1140 planted a vineyard at Edmondsbury in Suffolk, and William of Malmesbury says that vineyards were possessed by barons as well as by monks. [VINEYARD.]

There are various kinds of grapes, which grow wild and bear abundantly in North America, but they are very inferior to the varieties of *V. vinifera*. They belong to *V. Labrusca*, *V. cordifolia*, and others, and are called *fox-grapes* from their foxy perfume; their pulp is slimy and disagreeable.

Vitreous Copper-ore. A name for native sulphide of copper or COPPER GLANCE.

Vitreous Humour. The vitreous humour, so called from its glassy appearance, is the third or interior humour of the eye, filling a large portion of the eyeball, and greatly exceeding in quantity the aqueous and crystalline humours together. According to Sir D. Brewster, the refractive power of the vitreous humour is 1·3394. [OPTICS.]

Vitreous Silver-ore. Native sulphide of silver. [SILVER GLANCE.]

Vitrina (Lat. vitrum, *glass*). A genus of fresh-water Gastropods; so called from the extreme thinness and fragility of the shell, and its watery-green appearance. *Vitrina pellucida* and *Vitrina elongata* are natives of Great Britain.

Vitriol (Lat. vitrum; from the glassy character of its crystals). This term is applied by the old writers to crystallised sulphate of iron, or *green vitriol*; sulphate of copper and sulphate of zinc were afterwards called *blue vitriol* and *white vitriol*. [COPPER; IRON; ZINC.]

Vitriol, Oil of. The old name of sulphuric acid, which was originally obtained by distilling green vitriol. [SULPHUR.]

Vitriolite. A variety of sulphate of iron, in which part of the iron is replaced by copper. It occurs in the form of large stalactites and mammillary masses, in a cave near a mine of Copper Pyrites, in the interior of Turkey.

Vittæ (Lat. *fillets*). In Botany, the designation given to the narrow fistulæ or channels lodged in the coat of the fruit of umbellifers, and containing oil.

Vittie Vayr. The Tamul name under which perfumers sell the fibrous roots of the Khus-khus, Vetiver, or *Andropogon muricatus*, which contain an agreeable odorous oil. The *oil of lemon-grass*, and the *grass oil of Namur*, are obtained from the closely allied *Andropogon citratus* and *A. Calamus aromaticus*.

Vivace (Ital. *lively*). In Music, a term which, affixed to a movement, denotes that it is to be executed by the performer in a lively manner.

Viverridæ (Lat. viverra, *a ferret*). The name of a tribe of Carnivorous Mammals, of which the genus *Viverra* is the type. The characters of the Civet tribe are three premolars above, and four below; two tolerably large tuberculate molars above, one tuberculate and one sectorial molar below; the tongue beset with firm papillæ; claws more or less retracted: a large anal scent-gland and pouch.

Vivianite or **Blue Iron-earth.** A native hydrated phosphate of iron, composed of 28·75 per cent. of phosphoric acid, 42·27 protoxide of iron, and 28·98 water. It occurs in very long oblique prisms, frequently reniform and globular, also earthy and incrusting. The colour, which varies from pale green to indigo-blue, becomes darker on exposure. Named after the English mineralogist, J. G. Vivian.

Viviparous (Lat. vivus, *alive*, and pario, *I bring forth*). Those animals are so called which bring forth their young developed and alive, and commonly extricated from the egg coverings; as all the Mammalia, which were hence called Zootoka by Aristotle; many reptiles, as the viper or *viviper*; some fishes, and numerous invertebrate animals. In its restricted sense, the term signifies that mode of generation in which the chorion, or external tunic of the ovum, contracts a vascular adhesion with the uterus; and hence only the Placental Mammalia are truly viviparous, the rest being termed *ovo-viviparous*.

Vivisection (Lat. vivus, *alive*, and seco, *to cut*). A term used to denote physiological experiments upon living animals. This practice is more frequent in France than in England, and the only ground on which it can be defended is obviously that of the alleged needs of science. With the establishment or refutation of this plea, it must stand or fall. By those who altogether oppose it, the cruelty of such experiments is strongly insisted on. By those who justify it so far as it may appear absolutely necessary, it is answered that the sense of pain is far less intense in the lower animals than in man, and that the charge of gratuitous cruelty comes with a bad grace from any who uphold the custom of fox-hunting or stag-hunting; that even to an animal so highly organised as the horse, hunger is a source of greater uneasiness than that which is caused by a severe bodily injury; that the opening of the cavity of the peritoneum, for instance, is in man attended with serious danger, in dogs and other animals with little or none; and that this comparative insensibility is found in certain portions of the human race, as in Arabs contrasted with Europeans. The idea that vivisection is an indispensable condition for acquiring the highest surgical skill seems to be abandoned by all who have given their attention to this subject in this country; but the ascertainment of the effects of poisons (and this is strictly involved in the theory of vivisection) is, it is urged, often most necessary for purposes of justice, convictions having been obtained on the strength of experiments made on brute animals with the contents of the stomachs of persons alleged to have been murdered by poison. The necessity of the practice anatomically is defended on the authority of Sir Charles Bell, who states that he had recourse to experiments, although with great reluctance, when it seemed impossible to resolve a doubt by any other means. Thus, he says that 'it was necessary to know whether the phenomena exhibited on injuring the separate roots of the spinal nerves corresponded with what was suggested by their anatomy,' and that, after refraining long, he 'at last opened the spinal canal of a rabbit and cut the posterior roots of the nerves of the lower extremities,' &c. If, then, it be proved that vivisection is absolutely necessary for the general purposes of science, the practice, in so far as it is indispensably necessary, must be suffered to continue, and it may be remembered that in many cases the experiment destroys life more rapidly and with less pain than the clumsy strokes of the butcher, while in many others the pain may be mitigated, if not altogether prevented, by the use of chloroform. It may be safely laid down that 'the only fitting use of vivisection is for the purpose of proof and confirmation of a discovery otherwise arrived at, and that it is no more scientifically reasonable than it is morally justifiable to perform a number of experiments upon animals without a sufficient guide derived from previous investigation, and, in fact, without a clear and definite end in view.' Hence it follows 'that vivisections are not justifiable for the mere instruction of ordinary students; that they should be performed only by accomplished physiologists; that, when performed by them, they need be of a painful character only when the nervous system is the subject of investigation, and that even in this last case, in the present position of physiological science, vivisections are but very seldom necessary.' (*Westminster Review*, January 1866; Rowell, *On the Beneficent Distribution of the Sense of Pain*; *Report of the British Association*, 1863.)

Vizir (in Arabic *a porter*; and, by a singular metaphor, the title in various Oriental countries of a minister and councillor of state). The grand khalifs had their vizirs, who attained to the highest rank and consideration in their states, and were often more powerful than their masters; but after the creation of the new dignity of Emir-ul-omrah (commander of commanders), by Khalif Radhi, the older title lost much of its consideration. In Turkey, the councillors of state who sit in the divan, generally eight in number, are styled *vizirs*: and the chief among them *vizir azem*, rendered by us *grand vizir*, is the highest temporal dignitary in the empire.

Voandzeia (Voandzou, its Malagassy name). *V. subterranea* is the only known representative of this genus of *Leguminosæ*. It is a creeping annual, with long-stalked trifoliate leaves. The specific name, *subterranea*, has been given to it because its flower-stalks, like those of the *Arachis hypogæa*, bend down after flowering and increase in length, so that the

young pods are pushed into the earth, beneath which they ripen. It is a native of, and is extensively cultivated in many parts of Africa, from Bambarra and the coast of Guinea to Natal, its esculent pods and seeds forming a common article of food among the inhabitants of those countries. Although not indigenous to the western hemisphere, it is now commonly found in many parts of South America, such as Brazil and Surinam, whither it has been carried by the negro slaves, and has now become naturalised. The pods are sometimes called Bambarra ground-nuts; in Natal the natives call them Igiuhluba; while in Brazil they are known by the name of Mandubi d'Angola, showing their African origin, and in Surinam by that of Gobbe.

Vocative Case. In Grammar, the so-called case of exclamation or invocation. In strictness of speech it is not a case at all, and as having therefore no case ending, it represents simply the root of the word, on which the several cases are formed by means of pronominal suffixes.

Vochyaceæ (Vochysia, one of the genera). A natural order of hypogynous Exogens, consisting of trees or shrubs from tropical America, often of great beauty, and chiefly characterised by irregular flowers, four or five sepals, as many petals and stamens, or more frequently fewer, the stamens especially being often reduced to one, and always perigynous; and by a three-celled ovary, free or more or less inferior, the seeds usually without albumen. Little is known of the properties of these trees, beyond the hardness of the timber which some of them supply.

Voglite. A hydrated carbonate of uranium, lime and copper, which occurs in green scales having a pearly lustre, at the Elias Mine, near Joachimstahl, in Bohemia.

Voice (Lat. vox, vocis; Gr. ἔπος, for Ϝέπος [cf. ὄψ]; Sansc. vachas). The sound produced by the vibration of air emitted from the lungs of animals, which vibration is caused by an organ developed in the windpipe, called the *larynx*. Mammals, birds, and reptiles, are the only animals, which, according to the above definition, possess a voice; but many species of other classes produce peculiar sounds, by which the individuals are attracted to each other, or express their wants and feelings. A true organ of voice includes the lungs, bronchi, trachea, larynx, and mouth. The most essential parts are two vibratile chords bounding a slit-shaped aperture, called the *glottis*, and this may be situated at different parts of the air-tube in different animals; the portion of the tube between the glottis and the oral outlet being the true sonorous instrument. In mammals and reptiles the glottis is situated at the end of the wind-pipe, which communicates with the bronchial tubes, and consequently the whole trachea becomes, in this class, part of the vocal instrument. The organ of voice in reptiles consists of a simple larynx, without an epiglottis, the glottis being merely membranous, and not provided with fibrous vocal chords. Since neither fleshy movable lips nor soft palate exist in this class, the voice cannot undergo any further modification after its formation by the simple larynx. It consequently rarely rises beyond a hiss; and in the frog tribe, where the bones or gristles of the larynx are largest and most complicated, and the vibratile membrane of the glottis is best developed, the voice is only a more or less noisy croak.

In mammals, the air driven by the muscles of expiration from the lungs through the trachea strikes against the two vibratile *vocal chords*, which bound the sides of the glottis; and a voice is produced, varying in different animals, according to the power of regulating the degree of tensions of the chords, and according to the size and shape, and various complications of the laryngeal sacculi of the pharynx, of the tongue, and of the mouth and lips.

The superior organisation and mobility of the tongue and lips enables man to modify his vocal sounds so as to render them articulate, and adapted to express the ideas which it is his peculiar privilege to form. (Max Müller, *Lectures on Language*, second series, iii.) Although some quadrupeds possess the imitative faculty, and can be taught to do certain tricks, it would seem that the physical condition of their vocal organs is an insuperable impediment to their imitation of the human speech.

The sacculi or membranous pouches which communicate with the larynx in the gorilla, chimpanzee, orang, and most other quadrumanous animals, together with their thicker and more confined tongues and less flexible lips, are assumed to constitute the impediments to speech in them; but it may be doubted whether they have the imitative faculty for sounds possessed by the parrot or starling; and the absence of any voluntary application of their vocal organs for the purpose of speech is accounted for by presuming that they have nothing to say.

In birds, which possess the most diversified and complicated organ of voice, combined in some species with a high degree of imitativeness, instances are not uncommon, especially in the parrot and crow tribe, of an acquired power of forming articulate sounds superadded to the ordinary voice.

Voided. In Heraldry, a term applied to any ordinary when it is pierced through, so that the field which it overlies appears, leaving only the outer edge of the ordinary, e.g. a saltier, chevron, &c. voided. Voided per cross, when pierced with an opening in the shape of a cross, through which the field in like manner appears.

Voigtite. A mineral with nearly the same composition as Biotite, which replaces Mica in the granite of the western part of Ehrenberg, near Ilmenau.

Voire Dire (Nor. Fr. *to speak the truth*). In Law, according to ancient practice, an objection to the competency of a witness, in a trial at common law, was properly taken on a

preliminary examination, in which the witness was sworn *to speak the truth*, and then examined touching his interest in the subject-matter; but witnesses are not now incompetent on the ground of interest.

Volatile Alkali. [AMMONIA.]

Volatile Oils. [ESSENTIAL OILS.]

Volborthite. A native vanadiate of copper, which occurs in small tabular crystals of an olive-green or grey colour, at Sissersk and Nijni Tagulisk in the Urals. Named after Dr. Volborth.

Volcanic Garnet. A Mineralogical synonym of Pyroxene (Augite) from its occurrence in volcanic rocks. The name has, also, been given to Vesuvian, or the variety of Idocrase found at Vesuvius. [IDOCRASE; VESUVIAN.]

Volcanic Glass. A name commonly given to Obsidian from its glassy nature.

Volcanite or **Selensulphur.** A compound of selenium and sulphur, which is found on Vulcano, one of the Lipari Islands, and also in Hawaii.

Volcano (Lat. Vulcanus, the god of fire; a name akin to the Sanscrit ulkâ, *a firebrand*). The name given to a part of the earth's surface, whence vapour, mud, ashes, or melted rocks issue from a hollow depression in a conical hill or mountain. Generally the material already erupted, of whatever kind, has formed the hill, or where the point of eruption was already at a high level, has added the conical summit. [EARTHQUAKES.]

The geographical extent of volcanic districts is very considerable. It is true that the points of eruption and the movements of great earthquakes are confined to certain regions in which the volcanic vents are distributed at intervals, and most commonly in a linear direction; but there is evidence that similar powers are at work continuously throughout the intermediate spaces, for the ground is from time to time convulsed, gases and vapours are disengaged, and hot springs issue, the waters of which are very commonly impregnated with the same mineral matters which are discharged by the eruption of the volcano. [SPRING.]

There are also abundant proofs of the existence of volcanic fires under various parts of the bed of the ocean, where their effects, though at present unseen and unknown, are probably destined to become evident at some future but very remote period.

The substances thrown out by volcanoes are chiefly earthy and alkaline bodies in a state of fusion, together with red-hot and melted rock, stones, cinders, ashes, steam, and various gases; and although they differ very materially in the quantity of ejected matter, their products so generally agree in quality that they may doubtless be all referred to the operations of one cause. What that cause is, is a question not yet satisfactorily answered; we must, however, notice the perpetuity, as it may almost be called, of some active volcanoes—volcanoes which have continued to burn and throw out lava and cinders, not only for years, but for successive ages. The lava in the crater of Stromboli has been in a state of ignition for 2,000 years; so that there has here been a constant accession of heat, if not renovation of fuel.

We have ample evidence of the connection of earthquakes with volcanoes; and all great eruptions have commonly been preceded by violent convulsions, which have ceased upon the bursting forth of the volcanic fires, as if the pent-up matters had found a vent. All this shows the cause of the eruption to be deep below the surface. There is, further, a manifest connection between volcanic vents situated at great distances from each other. Such a connection has been traced not only between Vesuvius and Etna, but between these two volcanoes and those of the Greek islands at the distance of a thousand miles. Some of the volcanoes of the Andes appear to alternate in their eruptions, though at great distances from each other.

When lava is examined near the vent whence it issues, it is usually a semifluid mass about the consistence of honey. It soon cools externally, and its surface becomes rough and irregular; but, being a very bad conductor of heat, the interior remains red-hot long after the surface has cooled.

The quantity of matter which has been thrown to the surface by volcanic agencies during the historical period is very enormous, and may serve to give an idea of their influence in modifying the surface of the globe, when such powers are considered in reference to great periods of time. In illustration of this point we may select the volcanoes of Iceland, because our details respecting them are well authenticated; though it must be recollected that they fall into insignificance when compared with what has happened in some of those districts of Asia and South America which are ravaged by subterranean fires.

Iceland itself is little else than a mass of lava; and so intense is the energy of volcanic action in that region, that some eruptions of Hecla have lasted six years without ceasing. In this island, too, the volcanic vents are often in alternate action, one serving, as it were, for a time as a safety-valve to the rest; and when, as is often the case, new cones are thrown up, they generally take a linear direction. In 1783, a new island was thrown up off the coast, consisting of high cliffs; and with such an ejection of pumice, that the ocean was covered to the distance of 150 miles, and ships impeded in their course by the shoals of floating stones. Before a year had elapsed, however, the sea resumed her ancient domain, the volcanic cliffs had disappeared, and nothing was left but a rocky reef from five to thirty fathoms under water. In June, the Skaptar-Jokul, 200 miles distant from the new isles, threw out a torrent of lava, which in the first place flowed down into the river Skaptaa, and completely dried it up; its channel was between high rocks, and was in some places 400 to 600 feet deep and 200 broad. Not only did the lava fill these great defiles up to the brink, but overflowed the adjacent

country and filled up a deep lake. There was then a short intermission in the eruption; but in a few days it was resumed, and the newly ejected lava flowed rapidly over the surface of the first, and, damming up numerous streams, deluged the neighbouring country with water, and destroyed several villages; after flowing for several days, it was precipitated down a tremendous cataract, and filled the cavity which the waterfall had been hollowing out for ages. Afterwards the lava took a new direction, and discharged itself into the bed of another river (the Hyversfliot): the lava accumulated to a great depth, and coming to the plains spread out into broad lakes of fire, some of which were from twelve to fifteen miles wide, and 100 feet deep. When the fiery lake which filled the valley of the Skaptaa had been augmented by new supplies, the lava flowed up the course of the river to the foot of the hills where it rises. This eruption continued two years; and when Mr. Paulson visited it eleven years after (in 1794), the lava was still smoking, and its vents were filled with hot water. Although the population of Iceland did not exceed 50,000, twenty villages were destroyed, exclusive of those inundated by water; and all the cattle of the district, with more than 9,000 human beings, perished.

We have quoted the narrative of this eruption as giving, upon good authority, some notion of the extraordinary volume of melted matter produced. Of the two branches of lava (and they flowed nearly in opposite directions), one was fifty and the other forty miles in length; the extreme breadth of one branch was from twelve to fifteen, and of the other about seven miles. The ordinary height of the currents was about 100 feet; but in deep ravines and defiles they sometimes attained 600 feet.

But there are some phenomena connected with volcanic action which seem to be caused by yet more extraordinary agents than those already noticed, viz. their *great projectile and explosive force*. From the era of the discovery of the New World to the middle of the last century, the great volcanic district of Mexico had remained undisturbed. It is an elevated tract of broken ground, between 2,000 and 3,000 feet above the level of the sea, and bounded by hills of ancient igneous origin. It was occupied by fields of sugar-cane and indigo, and watered by two brooks. In June 1759, alarming sounds and earthquakes preceded the bursting forth of flame from the ground, and fragments of red-hot rocks were thrown to prodigious heights. A great chasm was formed, from which six volcanic cones were thrown up, the least of which was 300 feet high; and Jorullo, the central volcano, was brought by successive accumulations of erupted material to a height of 1,000 feet above the level of the surrounding country. It sent forth streams of basaltic lava, including fragments of granitic rocks, and its eruptions did not cease till 1760. Humboldt, visiting the country forty years afterwards, saw round the base of the cones, and spreading from them over an extent of four square miles, a convex mass of matter, between 500 and 600 feet high, gradually sloping in all directions towards the plains, and still so hot that he lighted a cigar in one of its fissures. It was covered with thousands of little mounds, which emitted steam and sulphuric acid. The two small rivers lost themselves below the east extremity of the plain, and reappeared as hot springs at its western limit. Humboldt attributed the convexity of the plain to inflation from below, supposing the ground for the extent of four square miles to have been puffed up like a bladder to the elevation of 550 feet in the highest part; but of this there seems no good evidence. A subsequent eruption of Jorullo happened in 1819, and it is much to be regretted that no European travellers have since visited the spot. It is known, however, that about the time of this eruption ashes fell in Guanaxuato, 140 miles from Jorullo, in such quantity as to lie six inches deep in the street; and the tower of the cathedral was thrown down by an accompanying earthquake.

Instances of similar volcanic action in the sea are not uncommon. In 1811 a volcano forced its way from beneath the sea off the island of St. Michael, one of the Azores, forming a crater above the water a mile in circumference, and about 300 feet high. In the middle of the seventeenth century an island was thrown up among the Hebrides, which in a month again disappeared. In July 1731, a volcano rose in the sea between the island of Pantellaria and the coast of Sicily, forming a crater 240 feet diameter and twenty feet above water. In 1866, a small group of islands rose out of deep water in the bay of Santorin, during a considerable eruption of lava. Many shoals are, no doubt, of volcanic origin.

The Pacific Ocean, in equatorial latitudes, seems to be one vast theatre of igneous action; and its innumerable archipelagoes, such as the New Hebrides, Friendly Islands, and Georgian Isles, are all volcanic, with active vents here and there interspersed. Of such a formation Owhyhee (Hawaii) is a magnificent example. The island is triangular in shape, the sides measuring respectively 100 miles, 88 miles, and 76 miles. Its whole area (4,000 square miles) is composed of lava. It contains three lofty volcanic summits, Mount (or Mauna) Loa, 13,760 ft., being the principal, and the others being about 14,000 ft. and 10,000 ft. respectively. The land slopes gently from the coast to the foot of the great cones, as in Etna, and thus their altitude is not observed. The area of the base of the great cone is, however, larger than the whole area covered with volcanic products in the neighbourhood of Etna. The crater of this great cone, Kilauea, is by far the largest in the globe, and is not surrounded by a cone of ashes as is elsewhere the case. The traveller rises on the slope of the dome (averaging only 6° 30′) to the edge of a pit, and looks down a depth (which before the last eruption in 1855 was about a thousand feet)

to a plain of bare naked lava more than two miles across—the bottom of a vast amphitheatre nearly eight miles in circuit. Within this amphitheatre is the great pit-crater itself. It is 16,000 ft. in length, and averages 7,500 ft. across. It includes an area of four square miles. When last described, there was in one part of it a throat or gullet full of boiling lava measuring 1,500 ft. by 1,000 ft. The lava is remarkably fluid, and rises occasionally to a great height, filling the whole area of the pit-crater to the height of many hundred feet. It generally finds a vent in the side of the mountain, without rising nearly to the top of the crater. Many great eruptions have taken place from this volcano within the present century. Those of 1823, 1832, 1840, and 1855, were the chief. They were all unaccompanied by earthquakes or ashes. As described many years ago by the Rev. Mr. Ellis, the gullet was even larger than it has been lately.

We may conclude this part of our subject with a brief notice of one other volcano, viz. that of Tomboroo in the island of Sumbawa, described by Sir S. Raffles. It began on April 5, 1815, when a Malay prow, while at sea, on the 11th, was enveloped in utter darkness; and the commander, afterwards passing the Tomboroo mountain, at the distance of five miles, observed that the lower part appeared in flames, while the upper portion was concealed in clouds. Upon landing to procure water, he found the ground three feet deep in ashes, and several large vessels thrown on shore by the concussions of the sea.

At the commencement of the explosion the commander of the E.I.C. cruiser Benares, which was at Macassar, supposed that there was an engagement of pirates somewhere in the neighbourhood, so closely did the reports resemble those of cannon. On the 11th, the ship was again shaken, as it was thought, by the discharge of cannon. At eight A.M. on the 12th, the face of the heavens to the south and west had assumed a dingy aspect, and it became darker than it had been at sunrise. A dusky red appearance gradually spread over the heavens; and by ten it was so dark that a ship could hardly be seen a mile off. By eleven, the whole heaven was obscured, except a small space in the east horizon, whence the wind came. The ashes now fell in showers, and the appearances were most alarming. By noon the light which had lingered in the horizon disappeared. At half-past seven the next morning there was a glimmering of light, and objects could just be perceived on deck. When day returned, the appearance of the ship was most singular; every part being covered with grey dust, which lay in heaps of a foot deep on many parts of the deck. On the 13th, the vessel left Macassar, and made Sumbawa on the 18th. Approaching the coast, she encountered an immense quantity of pumice, with numerous burnt trees and logs; and the anchorage was greatly altered, for the vessel grounded on a bank where there had previously been six fathoms water. The shores were entirely covered with ashes and cinders ejected from Tomboroo, forty miles distant. The explosions were terrific; and there is evidence of their having been heard in Sumatra, upwards of 900 nautical miles from Sumbawa. Lieut. Phillips, who was despatched to afford relief to the perishing inhabitants, learned from the rajah of Saugar that, on April 10, the fire and flame raged with exhaustless fury, till all became dark from the quantity of falling matter. At this time stones fell very thick, from the size of a walnut up to that of two fists; and the sea, rising twelve feet above its usual levels, swept away all within its reach, including some thousands of the inhabitants.

Of the eruptions of Vesuvius, we have many excellent narratives. From the remotest periods of which we have any tradition down to the Christian era, this volcano was in a state of inactivity; nor were there any other indications of its volcanic character than such as were deducible from the resemblance in its structure to other volcanoes, like the extinct volcanoes, as they are called, of the present day. Pliny does not include it in his list of active vents, but Strabo adverts to its volcanic aspect. Its form was then very different from that which it now exhibits, and the sides were covered with fertile fields. At its base were the populous cities of Herculaneum and Pompeii. The first symptom of renewed activity was in A.D. 63, when an earthquake shook the neighbourhood; and in August 79, it erupted lava. The elder Pliny, who commanded the Roman fleet, then stationed at Misenum, in his anxiety to get a near view of the phenomena, was suffocated by the exhalations. His nephew has given a graphic description of the scene, but has inexplicably passed over the destruction of Herculaneum and Pompeii. Indeed, so vague are the narratives long subsequent to that event, that if those buried cities had not been discovered, the accounts of their tragical end would probably have been regarded as fabulous. Tacitus, the friend and contemporary of Pliny, merely says that cities were destroyed; and the first writer who distinctly names them is Dion Cassius, who flourished about a century and a half after Pliny. We have some interesting historical facts, showing that Pompeii and Herculaneum were destroyed by ashes and mud, and not by red-hot lava. When the amphitheatre at Herculaneum was first cleared out, ashes were arranged on the steps just as snow would lie if it had fallen there: the whole superincumbent mass was from 70 to 112 feet deep. The foundation of both cities is ancient lava. Herculaneum, although buried to a much greater depth than Pompeii, was discovered first by the accidental circumstance of a well being sunk in 1713, which came directly down upon the theatre, where the statues of Cleopatra and of Hercules were soon discovered.

There are many instances of rocks of decided volcanic origin, i.e. extinct volcanic vents, in districts where all other trace of activity except

that which is shown by hot and mineral springs has been lost since the earliest historical times. Such are the Vivarais and Auvergne in Central France, and the district of Eifel, near Coblentz, on the Rhine. [BASALT; IGNEOUS ROCKS.]

Volcanoes, Mud. These curious phenomena, common in districts far removed from active volcanoes, but not unknown in their immediate vicinity, are the result of an inferior volcanic activity, which may be due either to an inchoate or to an effete and expiring volcanic energy; but our knowledge of their causes is still very incomplete.

In Europe, the most extensive phenomena of this kind have occurred in the eastern part of the Crimea, between the extremity of the Caucasus and the commencement of the Carpathians; on the southern flanks of the Caucasus, near Teflis; and in the delta of the Kuban, an important stream entering the Black Sea at its junction with the sea of Aral. On the promontory of Kertch, in the Crimea, very large masses of semifluid mud have been erupted, for the most part cold, though sometimes near the boiling point of water, and these have formed hills some hundred feet high and many miles in length. On the slopes of Mount Etna, and near Girgenti in Sicily, as well as on the northern slopes of the Apennines near Modena, similar phenomena have occurred, though on a smaller scale. In Java and in Mexico they are very grand in their developement, and in California on the eastern side of the mountains there are extensive tracts of the same general nature. They abound in Trinidad, and exist in Iceland. In almost every case the phenomena are the same: mud more or less liquid, bitumen in greater or less quantity, sulphurous vapours and eruptions, occasionally of solid mud or lignite.

It is probable that the conditions which, in most districts where hot springs occur, suffice only to bring clear water to the surface, are capable, under certain modifications, of lifting up mud and other products.

Volgerite. A mineral resulting from the alteration of Cervantite, and consisting of 60·3 per cent. of antimony, 18·8 oxygen, and 21 water. It occurs as a white powder or crust, and is named after Volger, by whom it was analysed.

Volition (from Lat. volo, Gr. βούλομαι, *to will*). The power of exercising the will. It is localised in the cerebral hemispheres, and probably to a certain extent in the *myelon*. [WILL, FREEDOM OF THE.]

Völknerite. A hydrated aluminate of magnesia, occurring in white, six-sided prisms with a pearly lustre, at the mines of Schischimskaja Gova, in the Ural. It is named after Völkner, a director of mines.

Volsunga Saga. The saga relating the story of SIGURDR, which is reproduced under different names, and with certain modifications, in the NIBELUNGEN LIED.

Volta-electric Induction. The term *induction*, as applied to frictional electricity, has been explained in art. ELECTRICITY. Not only is induction produced in neighbouring bodies by the presence of static electricity (electrostatic induction), but an induced current is also momentarily developed in adjacent metallic bodies by the action of dynamic electricity (electro-dynamic or volta-electric induction).

This important phenomenon was discovered by Faraday in 1831, and one of his fundamental experiments was made in the following manner: A long copper wire was wound in the form of a spiral round a cylinder of wood; a similar, but perfectly separate spiral, was then wound upon the same rod, the coils of each being interposed and close to each other, but nowhere in contact; the extremes of one of the wires were then connected with a galvanometer, and those of the other with a voltaic battery. At the moment of making contact with the battery, as well as of breaking it, the deflection of the galvanometer indicated a current of induced electricity in the proximate spiral; but in the interval, i.e. whilst the current of electricity was continuing quietly to flow, no deflection took place. The induced current was found to be in a direction opposed to the battery current upon making the contact, and in the contrary direction upon breaking it. The current from the battery is known by the name of the *primary* current, while the current induced in the adjacent wire is termed *secondary*, and the wires are in like manner called *primary* and *secondary coils*.

The first induced currents obtained in the manner described were only just sensible; but of late years the effects have been so exalted, that induction currents now furnish a most powerful source of electricity, and their luminous and physiological effects approach the nature, and, on a small scale, almost rival the grandeur, of a lightning discharge.

By the introduction of a soft iron core into the primary coil, the original effects have been much intensified; for, on the passage of the current, the iron becomes a magnet, and adds its own induction [MAGNETO-ELECTRIC INDUCTION] to that of the electric current. Further increase of power has resulted from carefully insulating the secondary coil, and greatly increasing its length and the number of its convolutions round the primary. Finally, by introducing into the primary current a mechanical means for rapidly making and breaking the circuit, and into the secondary circuit what is termed a *condenser* (consisting of a number of alternate sheets of tinfoil and varnished paper, in principle the same as a Leyden jar), a torrent of sparks, in some instruments as much as fifteen inches long, can be obtained from the terminals of the secondary coil. Some of the greatest improvements in the construction of *induction coils* or *inductoria*, as these instruments are now called, have been made by Ruhmkorff of Paris, and hence these instruments frequently go by the name of *Ruhmkorff's coils*.

Although the induced current lasts but momentarily, yet during its existence it can develope a second induced current in an adjoining wire, whose ends are connected. This second closed circuit can likewise develope a third in-

duced current in another adjacent wire, and thus induced currents of different *orders* and gradually diminishing intensity can be produced. These minor currents were discovered by Henry, and are termed currents of the third, fourth, &c. order, or tertiary and quaternary currents; they move alternately, in opposite directions.

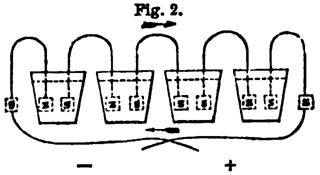
Voltaic Battery. The combination of a number of elements or cells, each of which generates a certain quantity of dynamic or voltaic electricity.

The first electro-motive apparatus was constructed by Volta in 1800, who arranged a series of discs of silver or copper, zinc, and then flannel or pasteboard soaked in salt-water or dilute acid. These discs were alternately laid on each other until a pile of them had been built up, A B, fig. 1. To the metallic ends of this pile, wires, *w w'*, were connected. With a

Fig. 1.

sufficient number of alternations, forty or more, a shock was felt on joining the wires, or the gold leaves of an electroscope could be diverged. The quantity of electricity set in motion by this means is small, but its tension, or power of overcoming resistances, is high; hence in character it is somewhat like frictional electricity, but differing from it in that its origin is directly chemical, and not mechanical action. It was soon conjectured, that if a perfectly dry pile could be constructed, the chemical theory of the battery would be disproved, and Volta's contact theory confirmed. [VOLTAIC ELECTRICITY.] To decide this point, De Luc formed a pile of pieces of zinc, silver, and writing paper, and with some hundreds of these discs succeeded in obtaining, apparently without chemical action, a source of weak electrical power, which by its attraction and repulsion could be made to produce a continuous mechanical motion. But though this combination will remain active for some years, its power gradually sinks from the oxidation of the zinc. Thus chemical action does even here take place, and arises from the moisture present in ordinary paper, for if the paper discs be previously well dried no manifestation of electricity occurs. Zamboni, in 1812, constructed a so-called *dry pile* of discs of paper rubbed over on one side with peroxide of manganese, and coated on the other with thin tin or silver leaf, generally sold attached to the paper. From its simplicity, durability, and comparatively high electrical power, this is one of the best dry piles.

Fig. 2.



But even the best of these piles are but feeble, and the inconvenience of their arrangement soon led Volta to the improved modification represented in the following diagram, fig. 2, which he called the *crown of cups* (couronne des tasses). The flannel or paper in the pile is rejected, and in its place a cup of dilute acid is substituted; in each of these cups is a plate of zinc and one of silver, so connected that each silver and zinc plate is in metallic communication, though in separate vessels: the arrangement being zinc, acid, silver; zinc, acid, silver, &c. The direction of the electric current is the same as in the simple circle, viz. from the zinc through the liquid to the silver [VOLTAIC ELECTRICITY, fig. 2]; but in this form of the apparatus, for the mere convenience of carrying on the series, the conducting wire connected with the first zinc plate has a supernumerary silver one attached to it, while the wire with the last silver plate has a supernumerary zinc plate. Hence much confusion has arisen in regard to the direction of the current in these cases, in consequence of calling what is here the silver extreme the *negative pole*, and the zinc extreme the *positive pole*; whereas it is in fact the reverse, and the circulation of the current goes on through the electrodes precisely as in the simple circle.

The cumbersome form of Volta's couronne des tasses was in a measure removed by Cruickshank, who, acting upon the idea of Volta's pile, soldered together the plates of zinc and copper, and used the metals themselves as the partitions of a long water-tight trough into which they were cemented, so as to leave intervening spaces, as shown in fig. 3. When required for action, dilute acid, or a saline solution, is poured into the cells thus formed. It was with a series of troughs of this kind, some of which are still preserved in the Royal Institution, that Davy made his memorable electro-chemical discoveries. Some inconveniences found in the last form of battery were removed by Dr. Babington, who devised the arrangement shown in the annexed cut, fig. 4. The plates of zinc and copper are here attached, in proper order and connection, to a piece of dry wood, so that they may at once be plunged into the exciting liquid contained in the cells of a porcelain trough over which they are suspended.

Fig. 3.

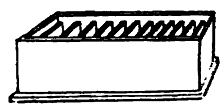


Fig. 4.

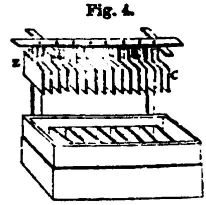

An important modification, as regards the arrangement of the plates of fig. 4, introduced by Dr. Wollaston, is represented in fig. 5; the copper plate C, instead of being single, is doubled over the zinc plate Z, actual contact being prevented by wooden cylinders placed between them. In this way much of the elec-

tricity lost in the preceding arrangements is brought into circulation.

In these arrangements, however, the electrical power is liable to fluctuation; and, after a time, various causes induce such a falling off in its evolution as to render them inconvenient, or even useless, where continuous or regular action is required. One of the reasons of this diminution of power (besides the saturation of the acid by the zinc dissolved during the action of the battery) is a *local action* on the zinc by which it becomes rapidly destroyed, even when the circuit is broken. This is due to the impurity of the metal, and can be prevented by *amalgamating* the zinc, a process best effected by dipping the plate in dilute sulphuric acid, and then rubbing it over with mercury. But, even after amalgamation, particles of the zinc are precipitated upon the copper plate, and, further, the hydrogen liberated at the zinc plate is carried over to the copper, and adheres as a film on the surface of the plate. Both these actions destroy the negative character of the copper, for hydrogen has electrical properties similar to zinc. The latter process, termed *polarisation*, is removed by an arrangement proposed by Smee. In this battery (fig. 6), the negative plate P is of silver, and is coated with a deposit of finely divided platinum: on each side of this plate are fixed two plates of amalgamated zinc Z Z′, and the whole is united to a clamp, and plunged in dilute sulphuric acid, about 1 of acid to 7 of water. The hydrogen, as it reaches the platinised silver, cannot adhere to the rough surface, and is given off with a hissing noise. The simplicity and power of this battery have brought it into frequent and extensive use.

Fig. 5.

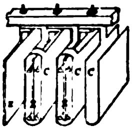

Fig. 6.

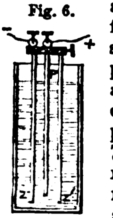
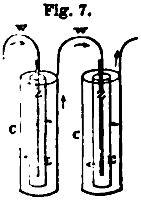


The most valuable improvement in the voltaic battery was suggested by Daniell, whose method obviates, to a great extent, both the inconveniences before mentioned, and by remaining in action for a long period well merits its name of *constant battery*. Fig. 7 shows the construction and arrangement of two Daniell cells. C C are cylindrical vessels of copper closed at the lower end; E E similar smaller cylinders of porous earthenware; Z Z are rods of amalgamated zinc, which are connected by the wires W W with the next copper cylinder, and so on in succession. The porous tubes are filled with dilute sulphuric acid (about 1 part of acid to 8 of water); and the copper cylinders are filled with a strong solution of sulphate of copper. The acid in the generating cells is thus separated from the solution of sulphate of copper; but the porosity of the tubes allows of their becoming so far imbued with the acid liquid as to admit of the passage of electricity, the current being in the direction of the darts. In this manner the sulphate of zinc is prevented from mixing with the sulphate of copper, and thus there can be no precipitation of zinc upon the copper. At the same time the hydrogen evolved in the copper cells or cylinders tends to reduce the oxide of copper, and continuously to throw down a film of metallic copper, with which the cells ultimately become lined. In proportion as the sulphate of copper is decomposed, fresh portions of that salt are added, and for this purpose there is a perforated receptacle or colander in the upper part of the copper cell, which is kept filled with crystals of sulphate of copper, the only change necessary being an occasional renewal of the dilute acid in the porous cells. This battery is superior to any as yet described, and in some respects has not been surpassed. The absence of fumes from it, its constancy and power, cause it to be in many cases invaluable for manufacturing use and scientific research.

Fig. 7.



One of the most powerful batteries yet constructed is that devised by Grove, upon the same principle as Daniell's. A rectangular plate of amalgamated zinc, Z Z′, is bent in the shape shown, in section, in fig. 8. The plate is immersed in dilute sulphuric acid, 1 of acid to 6 of water, contained in a porcelain vessel, A B. Within the bend of the zinc is a porous cell, filled with strong nitric acid, plunged in which is a plate of platinum, P. The hydrogen, before it can reach the platinum in the inner cell, is taken up by the nitric acid, and, decomposing it, liberates irritating red fumes of nitrous acid gas, the greatest objection to this battery. The power of this battery is greater than that of Daniell's, and from its compact arrangement is generally used in England for lecture illustration. On the Continent a modification of Grove's battery, proposed by Bunsen, is more frequently employed. In Bunsen's battery the hard coke obtained from gas retorts replaces the platinum in the porous cell, the other parts remaining the same. But, though the original expense of the battery is thus lowered, yet there are many objections to the substitution of coke, and hence we may consider Grove's battery to be for most purposes the best arrangement yet made.

Fig. 8.

The relative value of the different forms of voltaic battery has been variously estimated. The following tables are taken from Napier's *Manual of Electro-metallurgy*. The *electromotive force* or *strength* was compared by finding the amount of copper deposited from a solution of the sulphate during the same time. Only one pair of plates, exposing in each case the same surface of zinc, constituted the battery; the time in action was one hour.

	grains
Grove's battery deposited .	104
Daniell's " " . .	33
Smee's " " . .	22
Wollaston's " " . .	18

Hence Grove's battery has the highest electromotive force; but comparing the *constancy*, it will be seen in the next table that Daniell's has the advantage. Here the time was prolonged, the quantity of copper deposited being ascertained at the end of each hour.

In action	One Hour	Three Hours	Five Hours	Seven Hours
	grains	grains	grains	grains
Grove's battery .	104	66	54	45
Daniell's " .	33	34	32	31
Smee's " .	22	14	12	10
Wollaston's " .	18	15	11	10

The *time* and *cost* of depositing one pound of copper by these different batteries, found by actual experiment, is given in the next table. A single pair of large flat plates was used in each case.

	Time.	Cost.	
	hours	*s.*	*d.*
Grove's battery	19½	2	8
Daniell's "	49	3	4
Smee's "	147	2	4
Wollaston's "	151	2	3

Voltaic Electricity. This term is used to denote the phenomena resulting from the evolution of a current of electricity by chemical action. About 1790 Galvani noticed that the limb of a frog was convulsed if it happened to be touched by the extremities of two dissimilar metals when in contact at the other end. [GALVANISM.] Both Galvani and Volta thought, and rightly, that the convulsion of the frog was due to electricity; but both were wrong in their theoretical explanation of the source of this electricity. It is not the frog alone, as Galvani thought, nor the contact of dissimilar metals alone, as Volta supposed, that gives rise to the electric current, the physiological effect of which was observed by Galvani. It has now been abundantly proved by Faraday, that the source of voltaic electricity is a difference of chemical action, taking place between the intervening liquid and one or other of the metals.

Whenever substances act chemically upon each other, their normal electrical states are supposed to be disturbed; but the electricity thus evolved is, in ordinary cases, so lost and dissipated, as to escape observation. It may, however, be rendered manifest by the following simple arrangements: When a plate of pure zinc, or common zinc rubbed over or amalgamated with mercury, is dipped into a glass of very dilute sulphuric acid, little or no action is observed; nor does anything happen when a similar plate of silver is placed in the same cup of acid, provided the metals be kept apart from each other. But if, as in the annexed figure, the zinc and silver be brought into contact, at their extremities out of the liquid, the water is decomposed; its oxygen combines with the zinc to form oxide of zinc, which is dissolved by the acid; and its hydrogen passes over to the surface of the silver, where it collects, and ultimately escapes in gaseous globules. These phenomena are further connected with the production of a continuous current of electricity passing *from* the zinc across the water *to* the silver, and again from the silver, by metallic contact, to the zinc, in the direction represented by the darts. It is not necessary that the metals should be connected exactly as represented in the above diagram; but it *is* necessary, in order to establish the continuous electric current, that they should be somewhere in contact, or joined by a conductor such as a metallic wire. By modifying the preceding arrangement, so that the metallic contact between the plates be made at some distance from the vessel, as at the point A, fig. 2, the electric current takes the same direction, travelling through the liquid *from* the zinc or generating plate Z *to* the conducting plate S, and through the wires B and C back again to Z, as shown by the darts. Here again Z is oxidised and dissolved, and hydrogen is liberated upon S; but the moment that the circuit is broken, by parting the wires at A, these actions cease, because the electric current ceases to flow. Such an arrangement as that here represented is termed a voltaic *couple* or element. When the metals are disconnected at A, the circuit is said to be open; when connected, it is termed a *closed circuit*.

Fig. 1.

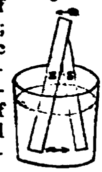


Fig. 2.

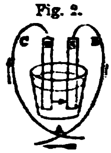


It is evident that if the production of a voltaic current depends upon a difference of chemical action on two substances, many other bodies in which this difference exists, besides zinc and silver, may be employed: for instance, for the zinc, tin or iron may be used; and for the silver, copper, platinum, and a hard kind of coke. Other liquids may also be substituted for the dilute sulphuric acid; the only necessary conditions for the generation of a voltaic current being that one *more* than the other of the two plates in each couple shall be chemically attacked by the interposed liquid, which, as well as the plates themselves, must be able in some degree to conduct electricity. The direction of the current is the same in all cases, viz. *from* the metal most attacked *to* that least attacked through the liquid, and in the opposite direction through the connecting wire.

As in frictional electricity, the part from which the current is supposed to proceed is termed the *positive pole*, and the part to which it flows is called the *negative pole*. Hence in fig. 2, S is the positive and Z the negative pole, *above* the exciting liquid; but beneath, the case

is reversed. The reason of this reversal is clear. The upper parts of the plate S Z, as well as the wires B C, are merely the channels, not the exciters, of the electric current; therefore, whatever may be the electrical disturbance imparted to them, they simply carry it on as conductors, and do not change its nature. To avoid misapprehension, Faraday has given to the terminals of the voltaic couple or battery the name *electrodes*, so that the end of B would be the positive and the end of C the negative electrode. Various substances may be interposed between these electrodes, or they may be plunged into different liquids; and if these are capable of transmitting electricity, the current will still pass, and the phenomena exhibited under a variety of circumstances may be studied. The current, however, was very feeble, and its observed effects very slight, until Volta succeeded in exalting the power of the current by the construction of what is now known as the *voltaic pile*, and still further by his *couronne des tasses*. [VOLTAIC BATTERY.]

Two hypotheses have been propounded to account for the origin of voltaic electricity. According to the so-called *contact theory*, ennunciated by Volta, whenever two dissimilar metals were placed in contact, they always assumed opposite electrical states. This unsatisfactory explanation has now been replaced by what is termed the *chemical theory*. According to this explanation, which has been established by the researches of Faraday, the generation of the voltaic current is referred to the *chemical action* going on in the cell between the zinc and the liquid, which we will assume to be water. It is supposed that the atoms of hydrogen and oxygen, of which water is composed, have inherently opposite electrical states, and are held together by their mutual attraction. It is further supposed that the metal zinc, for example, is electrically different from the state of the oxygen, whilst the electrical condition of the other metal (copper, for instance) is similar to the oxygen, but opposed to the hydrogen. Hence, when these metals are plunged in water and kept separate, their action upon the liquid excites a state of electrical tension between themselves and the particles of the water; a fact which can be ascertained by experiment. The tension is, however, far too feeble for anything like a discharge to take place between their terminals until the ends of the plates are joined, as in figs. 1 or 2. As soon as this is done, the tension is relieved, but is again aroused immediately, so long as the metals and liquid remain the same, only to be as instantaneously discharged; it is these successive discharges, which are linked into and are practically one, that give rise to the voltaic current. The current is, therefore, not created, nor evolved by contact. It is produced by the disappearance of an equivalent of another force; for it has been conclusively shown that the amount of electricity thus developed, or what is termed the *electro-motive force* of the current, is strictly proportioned to the quantity of the positive or oxidisable metal dissolved in a given time; and, further, if the compound which has been formed is or can be rendered liquid by being exposed to another current, precisely that amount of electricity which was generated in its formation will be needed to decompose the substance and restore it to its original condition.

If the wires from a small voltaic battery are terminated with platinum, or some other unoxidisable metal, and these electrodes dipped in acidulated water, bubbles of gas will be seen rising through the water as the electrodes are brought near to each other. These bubbles consist of oxygen and hydrogen gases, and result from the decomposition of the water by the force of the electric current. This fact was first noticed by Nicholson and Carlisle in 1800. The oxygen of the water invariably appears at the positive electrode, i. e. the electrode proceeding from the copper or other inactive plate: the hydrogen always rises from the negative electrode, i. e. the one in connection with the zinc plate. Two test tubes filled with water, and one inverted over each of these electrodes, will collect the rising gas, and show that the volume of the hydrogen liberated is twice that of the oxygen; these are exactly the proportions in which the two gases unite to form water.

A simple nomenclature has been adopted to avoid ambiguity, and to express briefly the facts of electro-chemical decomposition, of which the foregoing is an example. The word *electrode* has already been explained: it here expresses the surfaces where the current enters the liquid and round which the decomposed bodies collect. To the positive electrode, or that connected with the copper or inactive metal, Faraday gave the name of *anode*, and to the negative electrode the name *cathode*: the terms *zincode* and *platinode* have also been used to express the same things, but these words are not in very general use. The decomposition of a body by means of the electric current is termed *electrolysis*, and a substance capable of being *electrolysed*, or electro-chemically decomposed, is called an *electrolyte*. The bodies into which the electrolyte is split by electrolysis Faraday names *ions*; these are divided into two classes, those passing to the positive electrode called *anions* or electro-negative bodies, and those proceeding to the negative electrode called *cathions* or electro-positive bodies.

Besides water many other compounds have, in like manner, been decomposed by the electric current, and substances long regarded as elements were thus discovered to be compounds. By using a very powerful battery, Davy separated potash into the metal potassium and oxygen, soda into sodium and oxygen, and thus revealed these two remarkable metals the existence of which previously was not even conjectured.

It was not long before many other bodies were also found capable of electrolysis, and chemistry as well as physics received a

new impulse by the interesting and startling results thus obtained. Although at first much confusion prevailed from the multitude of new facts, yet it was soon observed that all the effects noticed were subject to regular laws, which in time were investigated and established. The following statements, abridged from Dr. Miller's *Chemical Physics*, comprehend the whole of these laws.

Laws of Electrolysis.—1. *No elementary substance can be an electrolyte.*

2. *Electrolysis occurs only whilst the body is in the liquid state.* This is necessary, in order that the transfer of the particles of the electrolyte which attends the decomposition may take place. Many saline bodies are good conductors and electrolytes when fused, though the thinnest solid film of the substance will arrest the passage of the current.

3. *During electrolysis, the components of the electrolyte are resolved into two groups: one group takes a definite direction towards one of the electrodes; the other group takes a course towards the other electrode.* Oxygen, chlorine, and the acids generally, make their appearance at the anode or positive electrode; whilst hydrogen, alkalies, and the metals are evolved upon the cathode or negative electrode. In the following table some of the elementary bodies have been classified in their electrochemical order; the list must not be taken as absolutely correct, as various experimenters have obtained a slightly different order, according to the purity of the metals used.

Electro-negative

Oxygen	Silver
Sulphur	Copper
Nitrogen	Bismuth
Chlorine	Tin
Iodine	Lead
Phosphorus	Aluminum
Carbon	Iron
Antimony	Zinc
Hydrogen	Magnesium
Gold	Barium
Platinum	Sodium
Mercury	Potassium

Electro-positive

Each substance in this table is electro-negative to the one below it; the greatest differences between any two bodies being found in those which are most widely separated. This table also exhibits what is called an electro-motive series, i.e. if any of the solid bodies in the list are immersed in dilute acid, and one of the bodies below it in the series be immersed likewise, a current will flow through the connecting wire from the one above to the one below in the list. And the greater the distance of the two bodies from each other in the series, the greater will be the electro-motive force of the current generated by their combination. The next law of electrolysis is one of great interest, and of theoretical as well as practical importance. It is as follows:—

4. *The amount as well as the direction of electrolysis is definite, and it is dependent upon the degree of action in the battery, being directly proportional to the quantity of electricity in circulation.* For example, it has been proved that for every 32·7 grains of zinc which are dissolved in any one cell of the battery if local action be prevented, 9 grains of water will be decomposed; or if fused iodide of lead be taken instead of water, 127 grains of iodine and 103·5 grains of lead will be separated for every 32·7 grains of zinc dissolved in the battery. These numbers correspond with the chemical equivalents of the foregoing substances. The discovery of this strict quantitative law led Mr. Faraday to construct an instrument for measuring the strength of the electric current. This instrument, called a *voltameter*, simply denotes the quantity of water, or other electrolyte, which the current has decomposed during a given time.

5. Finally, *those bodies only are electrolytes which are composed of a conductor and a non-conductor*. The conductors accumulate on the cathode or negative pole, and the non-conductors on the anode. A compound substance, consisting of two non-conductors, as bisulphide of carbon, or an alloy formed of two conductors, cannot be electrolysed.

The chemical action of the voltaic battery is not only a valuable agent in research, but is now practically employed on a large scale in some manufactures. It is used chiefly for the purpose of depositing a metal by electrolysis on the conducting surface to be coated. When a solution of sulphate is submitted to electrolysis, metallic copper is precipitated on the negative electrode, sulphuric acid appearing at the positive, where it is again converted into an equivalent of the sulphate if that electrode be of copper. Impressions of coins can thus be taken, and the metallic imprint produced is termed an *electrotype* or Voltatype.

Passing from the chemical action of the voltaic battery, we must notice briefly the phenomena exhibited by the electric current. When the poles of a powerful battery are grasped by the moistened hands, a continuous shock is felt, and the muscles of the body are violently convulsed. The physiological application of the battery, though at first frequently employed, has now been superseded by the use of the induction coil. [Volta-electric Induction.] When a few cells are connected by a wire, a spark is seen at the moment of making and breaking contact; if the number of these cells be increased, the spark becomes more brilliant, and at last glows with steady light, when a sufficient number of cells are employed. With electrodes of coke and a battery of thirty or forty of Grove's cells, a dazzling luminous arc is produced when the poles, having been brought in contact, are separated for a short distance. This is the electric light, and its intense brilliancy and enormous temperature have caused it to be largely employed for lecture illustrations: it has also of late been used for lighthouse illumination with much promise of success.

Not only does the electric current manifest itself when passing between the terminals of the battery, but in a closed circuit, as in fig. 2, the wire which conveys the current possesses extraordinary properties. In the year 1819 a Danish physicist, Oersted, was led to conclude, by the pure effect of reasoning, that the connecting wire of a battery had a magnetic condition. Experiments were made with this end in view; and from these, the same year, Oersted was able to announce, that when the voltaic current flowed through a wire it had the power of deflecting from the meridian a magnetic needle suspended in the neighbourhood of the wire. The direction in which the needle is deflected depends upon its position in relation to the wire, and upon the direction in which the current moves through the wire. If the wire is stretched in the magnetic meridian *above* the needle, and the current flows from *south to north*, the north end of the needle will be deflected towards the west. If one of these two conditions be altered, the effect is reversed; but if both the direction of the current and the position of the needle be inverted, the effect remains the same. By coiling the wire which conveys the current round and round the needle, the feeble action exerted by the single wire is multiplied by the simultaneous and similar action of every coil; hence by this means the effect of a weak current on the needle can be greatly exalted. This is the principle of the GALVANOMETER, which gave rise to the electric telegraph, and is an almost indispensable apparatus in many branches of physical research. Of whatever metal the wire may happen to be which transmits the electric current, it has, during the passage of the current, all the properties which belong to a magnet. Dipped in iron filings, a layer immediately gathers round the wire, and is held there till the circuit is broken. Coiled into a closed helix and suspended, copper wire is made to behave like a compass, turning one end to the north, and having its extremities attracted and repelled by the poles of an ordinary magnet. Steel placed within such a coil becomes a powerful and permanent magnet; and, by winding the wire from a battery round soft iron instead of steel, magnets of enormous power are produced so long as the current flows. These temporary magnets, formed by sending a current of electricity round soft iron, are called *electro-magnets*, and are further described under the word ELECTRO-MAGNETISM.

The *intensity* of the voltaic current at any point in a circuit is found by dividing the electro-motive force of the battery by the resistance—which the current encounters as it traverses the liquid in the cells of the battery and in the wire which joins its poles. The resistance arises from the fact, that electricity passes with greater ease through some bodies than through others. Those substances which transmit the current freely are termed *conductors*, and those which resist its passage *non-conductors*. The metals are of the former class (as also, more or less, are liquids), and gases are of the latter. The metals also differ in conductivity among themselves. This will be seen from the following table, which gives some of the results obtained by Matthiessen on the electric conductivity of commercially pure bodies, the best conductors being represented by 100.

Silver	100	Potassium	20·8
Copper	77·4	Iron	14·4
Gold	55·2	Platinum	10·5
Sodium	37·4	Lead	7·7
Aluminium	33·8	Mercury	1·6
Zinc	27·4	Graphite	0·07

The temperatures of these substances were not all the same; when silver and copper are compared at the same temperature, the difference between them is less than that given. An increase of temperature diminishes the conductivity of solids, but increases that of liquids; these bodies are, however, at all temperatures far inferior to solids as conductors of electricity. If the conductivity of silver be taken as 100,000,000, that of dilute sulphuric acid (1 of acid to 11 of water) would be only 89; and that of a saturated solution of common salt only 31·5, whilst distilled water is represented by the number 0·013, practically a non-conductor. Gases are almost absolute non-conductors of voltaic electricity.

When the electric current traverses bad conductors, the resistance which it experiences causes a part of the current to disappear, but at the same time the resisting medium becomes hot. It has been proved by Joule, that, for currents of equal strength, the heat developed in a wire is directly proportional to the resistance of the wire, i.e. inversely as its conducting power; and, for the same wire, the rise in temperature is proportional to the strength of the current. By using an imperfect conductor, as platinum, many feet of a wire of such a metal may be raised to incandescence, and even fused, merely by the passage of a powerful electric current.

A very copious source of voltaic electricity has recently been obtained from a new application, by Mr. Wilde, of Faraday's discovery of magneto-electricity. In the course of some experiments Mr. Wilde noticed that a small amount of dynamic electricity, when sent round an electro-magnet, produces an indefinitely large amount of magnetism, and by the rotation of a suitable armature in front of such a magnet an indefinitely large amount of electricity is capable of being evolved. No battery at all is necessary; for the current, in the first instance, can be derived by rotating an armature covered with a bobbin of wire in front of a permanent magnet. Starting, then, with a small magneto-electric machine, Mr. Wilde sends the feeble current obtained from it through the coils of an electro-magnet of large dimensions. In front of this magnet another armature revolves, generating a second

and more powerful current. This stronger current is then sent round a second electro-magnet of enormous size. The weight of this magnet is nearly three tons, and its strength, when excited as just described, is enormous. By the revolution of an armature between the poles of this magnet, so great a current of electricity is generated that it can melt pieces of iron rod 15 inches long and ¼ of an inch in diameter, or can heat to redness 21 feet of No. 16 iron wire. The light given between two coke points by this current is so intense, that it is said to cast shadows of the flames of street lamps a quarter of a mile off, and at that distance the rays from the reflector appeared like sunlight. Sensitive paper, when exposed for 20 seconds, at 2 feet from this light, was darkened as much as by one minute's exposure to the direct rays of the midday sun. These brilliant effects are not, however, obtained without the expenditure of force; for it has been found that very considerable steam power is required to revolve the armatures in front of the electro-magnets. Mr. Wilde has thus converted the mechanical motion generated by the expansion of steam by heat into the most powerful source of voltaic electricity with which we are yet acquainted.

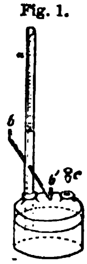
Still more recently (February 1867), Dr. Wheatstone and Mr. Siemens have simultaneously announced their independent discovery of another means of obtaining powerful currents of magneto-electricity by somewhat similar means.

Voltaite. A species of iron-alum, which occurs in dull oil-green to brown or black cubical crystals, and their modifications, at the Solfatara near Naples, and at the Rammelsberg mine, near Goslar in Hanover. Named in honour of the Italian physician, A. Volta.

Voltameter (Ital. volta, and Gr. *μέτρον, a measure*). An instrument contrived by Mr. Faraday for measuring the electro-motive force or strength of a current of voltaic electricity.

The indicating body used in this instrument is generally water acidulated by sulphuric acid. The electrodes are plates of platinum; and the quantity of electricity which has passed is indicated by the quantity of oxygen and hydrogen, resulting from the decomposition of the water, which is evolved, or, in other words, by the weight of water decomposed.

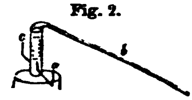
Fig. 1.



When the strength of the current is small, the voltameter represented in the margin is a good form: *a* is a graduated straight tube closed at the upper end, and including two platinum electrodes, connected with the external wires *b b*; through these is sent the current the strength of which is to be determined. The tube is fitted by grinding it into one mouth of the double-necked bottle containing the acidulated water, and is filled by inclining the bottle. When an electric current is passed through the instrument, the gases evolved collect in the upper part of the tube and displace the dilute acid, the stopper *c* being left open. The amount of the gases liberated is read off on the graduated tube, which can be at once refilled by replacing the stopper *c*, and inclining the whole instrument. For every 32·7 grains of zinc dissolved in any one cell of the battery, 9 grains of water are decomposed in the voltameter, and 46·6 cubic inches of hydrogen, or 1 grain, and 23·3 cubic inches of oxygen, or 8 grains, at 60 Fahr. and 30 inches Bar., are evolved upon its plates; at the same time, 46·6 cubic inches of hydrogen are evolved from every platinum plate in the cells of the battery (Miller).

When large quantities of the mixed gases are to be measured, as in cases where the current is left continuous for several hours or days, a voltameter of the accompanying form may be used.

Fig. 2.



The evolved gases pass by the tube *b* into a pneumatic trough, where they are received in a graduated jar and measured: *c c* are the projecting wires by which communication is made with the platinum electrodes, seen as a dotted line inside the glass cylinder, which is nearly filled with acidulated water.

Voltatype or **Electrotype.** The cast of an object obtained by the gradual deposition of a metal from a metallic solution through the agency of a current of electricity. The process can be illustrated as follows: If two pieces of clean platinum are plunged into a solution of sulphate of copper, no change takes place. But if an electric current be now transmitted through the solution, by means of these platinum plates, copper is immediately precipitated upon the platinum, which forms the negative electrode, or cathode, the positive electrode, or anode, remaining clean. If the current be now reversed, the copper will be removed from the platinum plate upon which it had just been deposited, and will be transmitted to the clean plate; and thus, by reversing the direction of the electric current, the copper may be sent backwards and forwards, being always deposited upon the negative pole, or, in popular phraseology, upon that surface by which the electric current leaves the electrolyte, or solution that is undergoing decomposition. By a continuance of the electric current, and keeping up the strength of the solution by the occasional addition of fresh portions of the salt of copper, the metallic film upon the cathode may be obtained of any required thickness, and may afterwards be peeled off the platinum surface. The texture of the deposited copper varies with the battery power employed, and with the temperature and strength of the solution: so that it may be obtained hard, brittle, and crystalline, or malleable and tough, or even pulverulent, according to the management of the operator. A current of low intensity, a moderately strong solution of sulphate of copper acidulated with sulphuric acid, and a temperature not below 60° or 70°, are the cir-

cumstances under which the best deposit of copper is usually obtained for the purposes to which this process is commonly applied.

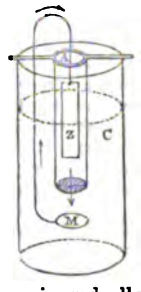
When the negative pole or cathode, instead of being, as above represented, a plane surface of platinum, is irregular (like a medal or coin), an exact impression of the device may be taken off on the precipitated copper. Copies or plates of this kind are known by the name of *voltatypes*, or more frequently are now called *electrotypes*. Gold, silver, and other metals may, by proper management, be substituted for copper; or, if the precipitated metal be left upon the surface on which it is thrown down, gilding, silvering, and coppering may be extensively and beautifully effected. Thus it is that the art of *electro-plating* has also arisen out of these electro-chemical actions.

The merit of first introducing this now well-known and valuable art has been ascribed to several persons. It appears that, in working with his battery, Daniell was the first to notice the deposition of metallic copper by electricity; that, in 1839, Jacobi of St. Petersburg was the first to publish a practical application of this fact, the publication of which evoked announcements from two Englishmen, Spencer and Jordan, each of whom was independently working at the same object, and had attained the same end as Jacobi. Messrs. Elkington almost immediately applied the process to the plating and gilding of goods on a large scale, and their manufactory still holds the first place in this country.

To become an expert at electrotyping, or the *galvano-plastic* art, as it used to be called, requires but little apparatus, and involves but a trifling expense; intelligent care and patience here, as elsewhere, are sure to bring success. Supposing it were wished to take a copy of a medal—it may either be copied directly, and an inverted impression obtained from which a second electrotype can be taken; or a cast of the medal may first be made in wax or plaster. If the latter and most general plan be adopted, the mould, if of plaster, must be first soaked in oil, or immersed in melted spermaceti or tallow so as to render it impermeable to water. The wax or plaster mould must then be made a conductor of the current, and this can be done by thoroughly brushing black-lead over the surface which it is intended to reproduce. When the medal itself is used, in order to prevent the deposition of copper, which would take place upon the edges, and upon the reverse of the medal, those parts should be covered with shell-lac or sealing-wax varnish.

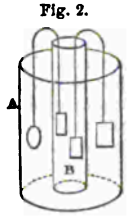
The medal or mould, after being hung in a loop of copper wire, is now ready for the following simple voltaic arrangement: A is a glass cylinder (a common lamp-glass answers the purpose), closed at bottom with a piece of bladder, or with a plug of plaster of Paris, and filled with dilute sulphuric acid (1 of acid to 8 of water by measure); Z is a piece of amalgamated zinc immersed in the acid, and connected by a copper wire with the medal M; C is a jar, or glass tumbler, nearly filled with a strong solution of sulphate of copper, acidulated by the addition of about a tenth part of sulphuric acid. In this arrangement, the acid in the generating cell is prevented from mixing with the solution in the jar by the diaphragm of bladder or plaster; which, however, when thoroughly wetted, suffers the electric current to pass from the zinc to the medal (or negative pole), and so through the wire, in the direction of the darts, back to the zinc. In this way a film of metallic copper is gradually thrown down upon M, which goes on increasing, and when sufficiently thick (perhaps in 24 or 30 hours), the wire with Z and M at its ends is lifted out. By inserting the point of a knife the deposited copper is released, and when pulled off of M presents a faithful and minute impression of the object.

Fig. 1.



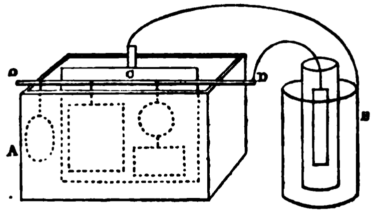
In the case of seals, coins, and other small articles, a number of them may be put in process at once by the following modification of the above described apparatus. A is a jar filled with a saturated and slightly acid solution of sulphate of copper; B is a porous earthenware cylinder, similar to those used in Daniell's constant battery, filled with dilute sulphuric acid. The articles to be coated with copper are prepared as above described, and attached to copper wires having a small piece of zinc at their other end; several of these may then be suspended round the porous tube; and thus the zinc being in the acid, and the coin or seal in the cupreous solution, the process goes on until the electrotype is perfect.

Fig. 2.



When a number of articles of different sizes are to be electrotyped, the following arrangement is generally adopted where the process is employed upon a large scale; as in preparing electro-types from wood-cuts, copper-plates, plaster casts, &c. A is a trough of any required dimensions, made of slate or wood, generally lined with marine glue, and filled with a proper solution of sulphate of copper; C is a copper plate immersed in the trough, and

Fig. 3.



forming the positive electrode of a Daniell's battery B (of which one cell only is here represented, but of which two or more may be employed as required); D D is a copper rod forming the negative electrode, to which the articles to be coated with copper are suspended by copper wires. These several articles, previously prepared as described, are retained in the circuit till adequately coated by copper. In this form of apparatus the sulphate of copper solution is maintained at its original strength; for, as the copper is deposited upon the mould, the sulphuric acid liberated at the positive pole converts an equivalent of the copper of the plate C into the sulphate. Numerous applications have been made of the process of electrotyping; engravings are copied, music is printed, busts and other figures are cast, ferns, seaweed, and flowers moulded in metal, and above all daguerreotypes reproduced, with wonderful faithfulness and detail.

The other application of electro-metallurgy is the covering one metal with a thin crust of another; a process even more generally useful than the reproduction of objects. For coating articles with silver, a bath is made containing 1 part of cyanide of silver to 2 or 3 parts of cyanide of potassium, dissolved in about 150 parts of water. The article to be plated is made the negative pole, and a piece of silver hung in the bath forms the positive electrode. The silver will be deposited with a dead appearance; if lustre is required, a few drops of bisulphide of carbon added to the bath will effect this object. Articles may also be gilded by employing a solution of the double cyanide of gold and potassium. In all cases where silver or gold is to be deposited, so as to give a durable adhesive coating, the articles must be perfectly clean. For this purpose they must be boiled in a weak alkaline solution, then dipped in dilute nitric acid, and afterwards well washed immediately before putting them in the bath. Other metals, besides copper, silver, and gold, can be electrically deposited from their solutions; of these the most successful and useful as yet employed is the coating of iron with zinc, a solution of sulphate of zinc being here employed. Alloys of the metals have also been deposited, but the processes are attended with practical difficulties. [VOLTAIC BATTERY.]

Volti (Ital. *turn*). In Music, a term directing that the leaf is to be turned over.

Voltzine or **Voltzite.** A native oxysulphide of zinc, composed (when pure) of 82·7 per cent. of sulphide of zinc, and 17·3 oxide. It occurs in small hemispherical incrustations of a dirty rose-red colour, which are opaque or only slightly translucent, and have a vitreo-resinous lustre, at Rozières, near Port Gibaud in Auvergne; and at the Elias Mine, near Joachimsthal, Bohemia. Named after Voltz, French engineer of mines.

Volubilis (Lat. *rolling*). In Botany, a term applied to stems or leaf-stalks, and similar bodies which have the property of twisting round some other body.

Volume (Lat. volumen, from volvo, *I roll*). A book. Thus a library is said to consist of so many thousand volumes, and a long work is divided for convenience into several volumes. Every single roll of paper or parchment, in an ancient library, was of course equivalent to a single book in one of our own. The French word *tome* (signifying, properly, a single volume of a work containing more than one) is the Greek *τόμος*, from *τέμνειν*, *to cut* or *divide*.

VOLUME. In Geometry, this term denotes the quantity of space, of three dimensions, enclosed by a surface or surfaces. The volume of a body, or its *solid content*, is the quantity of space which it occupies. For methods of estimating volumes, see CUBATURE.

Volumetric Analysis. A method of quantitative chemical analysis in which the balance and other elaborate apparatus are more or less dispensed with; a few glass vessels, some graduated, being alone necessary. It consists in ascertaining how much of a solution of definite strength and properties must be added to a solution of unknown strength before a given effect, indicative of the termination of a chemical reaction, can be produced. Many solutions of unknown strength can thus have quantitative values rapidly given to them. For illustrations of the process, see ALKALIMETRY.

Volunteers. The most ancient volunteer force in Great Britain is the Honourable Artillery Company of the city of London, which is perhaps the oldest military body in Europe, and received a charter of incorporation from Henry VIII. When Napoleon's design to invade England in 1803 became known, a large force of volunteers was enrolled, the returns for that year showing 463,134 effectives. The numbers soon declined, and shortly after 1815 they ceased almost entirely to exist.

The volunteer organisation as now established arose in 1858, though the Victoria Rifles, and one or two other corps, had been formed previously. In 1859 a large force was formed, and an inspecting staff established. The Act 26 & 27 Vict. c. 65 (1863) now regulates the formation and system of volunteer corps. They are also subject to the provisions of the Order in Council, July 27, 1863, and to all regulations made regarding them by the Secretary of State for War.

In time of peace the adjutants and serjeant instructors are subject to the provisions of the Mutiny Act and Articles of War. The other officers are not subject to military law, but can be deprived of their commissions by authority of her majesty; and the non-commissioned officers and privates are liable to fine and dismissal under certain rules. In case of invasion, actual or apprehended, her majesty may direct the lords-lieutenant of counties to call out any volunteers, who are bound to march anywhere within Great Britain. All officers and men thus called out become subject to the Mutiny Act and Articles of War, and receive pay and allowances corresponding to

those of the similar branches of the regular army.

The volunteer force, including yeomanry, takes precedence immediately after the militia; and the various corps rank as under: light horse artillery; engineers; engineer and railway transport; mounted rifles; rifles. On the formation of a corps, it receives an establishment and a number.

The members of a corps are either *honorary* or *enrolled*. Enrolled members are classed as *efficient* and *non-efficient*. The qualifications for efficient members are defined by an Order in Council of July 27, 1863.

The staff of the volunteer force consists of 1 inspector-general, 1 deputy inspector, 10 assistant inspectors, and 3 honorary inspectors of musketry. The pay and allowances for the volunteer force are as follows: Adjutants and serjeant instructors receive permanent pay and allowances. An annual capitation grant of 30*s*. for each effective volunteer is given to each artillery corps: 20*s*. for other corps, with a special allowance of 10*s*. each for men fulfilling certain conditions. Administrative battalions have, under certain regulations, an extra allowance of 4*s*. for each effective. Arms and ammunition for practice are supplied at the public expense.

The total number of yeomanry and volunteers now (1866–7) borne on the muster rolls is 193,523 of all ranks, which are as follows: Yeomanry cavalry, 14,268. Volunteers—Staff at head quarters, 12; adjutants, 280; Honourable Artillery Company, 901; light horse, 830; artillery, 32,010; engineers, 4,823; mounted rifles, 438; rifles, 139,961. For further information, see *Army of Great Britain*, published annually by authority, at the statistical department of the War Office.

Voluspa Saga. A short saga, in which a theogony is combined with a cosmogony, and in which the fortunes of the world are traced to the twilights of the gods when Odin and the Æsir are all doomed to perish. The age of this saga is doubtful.

The word Voluspa means the *spa* (Scotch *spae*), or prophecy of Vola, the inspired or mad prophetess (whence the English *fool* and *folly*). With the first part of this word may be compared the name of Veleda, the prophetess of the Bructeri, mentioned by Tacitus. (*Hist.* iv. 61.)

Voluta (Lat. *a volute*). A name applied by Linnæus to a genus of the *Vermes Testacea*, including those which have a univalve spiral shell, with an aperture without a beak, and somewhat effuse; and a columella twisted or plaited, generally without lips or perforation. The Mollusca thus characterised form a family in the Buccinoid tribe of the Pectinibranchiate Gastropods of Cuvier's system, and are distributed into the following subgenera: *Oliva*, Brug.; *Volvaria*, Lam.; *Voluta* proper; *Cymbium*, Montf.; *Marginella*, Lam.; *Columbella*, Lam.; *Mitra*, Lam.; *Cancellaria*, Lam.

Volute (Lat. volvo, *I roll*). In Architecture, the spiral scroll appended on each side to the capital of the Ionic order. The Corinthian and Composite capitals are also decorated with volutes; but their character is different, their size smaller, and they are always diagonally placed. In the Corinthian order they are more numerous, and in the Composite they are larger than in the Corinthian.

Volva or **Wrapper.** In Botany, a term used in describing fungi to denote the involucrum-like base of the stipes of *Agaricus*. It was originally the bag enveloping the whole plant, but was left at the foot of the stipes when the plant elongated and burst through it.

Volvulus (Lat. volvere, *to roll up*, because it was supposed to arise from twisting of the intestines). The contractile action of the membranes of the intestines, usually termed *cholic* or *gripes*. [Iliac Passion.]

Vomica (Lat. vomo, *I spit up*). A cavity in the lungs, which is the result of softening of deposited tubercle in phthisical persons. These cavities apparently may also result from degeneration and softening of fibrinous material deposited in the lung.

Vomicina or **Vomicine.** A name given by some pharmaceutical chemists to the alkaloid more usually termed *Brucia*, obtained from the bark and seeds of the *Nux vomica* and from *St. Ignatius' bean*; it is usually associated with *Strychnia*. [Brucia.]

Vomitoria (Lat. vomo). In Architecture, the openings, gates, or doors, in the ancient theatres and amphitheatres, which gave ingress and egress to the public.

Voraulite. A name for the ferro-magnesian phosphate of alumina, met with in a gangue of quartz, at Waldbach, near Vorau, in Styria. It appears to be a species of *Blue Spar* or *Lazulite*.

Vorhauserite. A mineral from the Fleims Valley in the Tyrol, with the same composition as Retinalite, but rendered impure by an admixture of small quantities of theoxides of manganese and iron. Named in honour of Vorhauser, a Tyrolese minister.

Vortex (Lat. another form of vertex). An eddy or whirlpool; a body of water running rapidly round and forming a cavity in the middle, into which floating bodies are drawn. The term is also applied to whirlwind.

In the Cartesian philosophy, vortex signifies a collection of material particles, forming a fluid or ether, endowed with a rapid rotatory motion about an axis. By means of this hypothesis and the received doctrine of centrifugal forces, a plausible explanation may be given of the motion of the planets, which move nearly in the same plane; but the motions of the comets which traverse the heavens in all directions are inexplicable, and in fact are inconsistent with the hypothesis. Descartes, nevertheless, had the merit of attempting to show how the universe might have assumed its present form and be preserved on mechanical principles. For an explanation of the system of vortices, see Maclaurin's *Account of Newton's Philosophical Discoveries*.

Electric and magnetic phenomena have also been explained by the *Theory of Molecular Vortices*. (*Phil. Mag.* 1861.)

Vorticel (Lat. vortex). The generic name of certain pedicellate Wheel Animalcules, provided with vibratile organs at their anterior extremity, whose apparently rotatory actions produce little whirlpools in their vicinity, and thus attract the particles of food.

Vosgite. A kind of Labradorite which has become hydrous through undergoing a partial alteration, and which constitutes the porphyry of Ternuay in the Vosges.

Voussoir. One of the wedge-shaped stones of an arch, by the proper disposition of which, in a semicircle or other curve, the arch is formed. The centre stone of the arch is called the *key stone*. The inferior surface of the arch is called the *intrados* or *soffit*, and the exterior the *extrados* or *back*.

Vow (Lat. votum). Solemn promises to God, and under religious sanction, are spoken of in the Old and New Testaments under this name. The Jews recognised three sorts of vows: of devotion, of abstinence, of destruction or extermination (anathema). In the Church of Rome, vows are divided into *solemn* (taken in the face of the church) and *simple* (or private). Release from a vow must be obtained from a spiritual superior, who has power to grant it. Five vows were said to be reserved for papal dispensation only: that of chastity; the vow to enter into a religious order; vows of pilgrimages to Rome and to Compostella; and the vow of a crusade. Monastic vows are now most commonly understood when vows are spoken of. [Monachism; Orders, Religious.]

Vowel (Fr. voyelle; Lat. vocalis, from vox; Gr. ἔπος). In Grammar, a letter which can be pronounced alone, thus distinguished from consonants, which require to be sounded with the aid of a vowel. They are divided in ancient prosody into *long*, *short*, and *common* (ancipites, i.e. either long or short at pleasure). A diphthong consists of two vowels, of which the sounds run (or are supposed to run) into one another.

Voyol. A rope used on Shipboard to bring the pressure of the capstan to bear on the cable without the necessity of winding the latter round the barrel.

Vritra. In the Vedic Mythology, the cloud-enemy of Indra, who lets loose the imprisoned waters by putting him to death. The idea expressed in the myth is precisely that which is embodied in the legend of the Theban Sphinx. The name Vritra denotes a being who hides or veils, and belongs to the same root with Varuna [Uranus], and reappears in that of the Greek Orthros [Cerberus]. This monster is identical with Ahi, the great serpent or throttler, who reappears in the Greek Echidna, the Latin anguis, from the root *ah*, or anh (as in ango, angina), *to throttle*. Thus in the Vedic hymns Indra is especially known as Vritrahan, or the slayer of Vritra, and thus also Vritra became, in course of time, a mere generic name for an enemy. In the conflict he stands to Indra in precisely the same relation as Geryon or Cacus to Heracles. But, as with other early Vedic beings, the names are not finally fixed, and the attributes are to a certain extent interchangeable. Vritra is called sometimes Ahi, sometimes Vala, Pani [Paris], &c. and he is opposed sometimes by Indra and at other times by Agni, Trita [Tritogeneia], and other gods. Like Cerberus, Vritra has three heads, and he swallows the cows, which Indra rescues from his jaws, as Hercules delivers them from the cave of Cacus. These cows are the clouds which water the earth, and are prevented by malevolent powers from bestowing their gifts on the sons of men. Thus, in Greek myths, dragons are commonly represented as guarding fountains. Cadmus kills the monster who kept the fountain of Ares, near Thebes; a stream of water leaped up from the earth when Apollo slew the Python; and the apples guarded by the dragon in the land of the Hesperides are only the cattle (μῆλα, the same word having both meanings) which in the *Odyssey* are fed by Phaethusa and Lampetie in the pastures of the sun.

In India, this myth retained to the last, in great measure, a merely physical signification. The battle between Indra and Vritra was the battle of the sun-god with the dark thunder-clouds which keep the rain from falling on the earth; the struggle of Œdipus with the Sphinx, of Achilleus with Hector, of Odysseus with Melanthius and his accomplices. But the tendency to invest the myth with a moral or spiritual meaning is manifest in some Vedic passages which contain a prayer beseeching Indra with the Maruts [Thor] to smite Vritra, 'that the wicked one reign not over us;' but the change was not fully accomplished till the myth was transplanted to Iranian soil; and there from it sprang the Zoroastrian Dualism which divided the empire of the Cosmos between the beneficent Ormuzd and the malignant Ahriman. But although the myth, thus spiritualised, assumed a form which has exercised a momentous influence on religious belief down to the present day, the names remained for the most part the same. The Vedic Vritra reappears in the Zend Verethra, and Vritrahan is seen in Verethragna (the modern Behram). Nor is the name Ahi wanting. The throttling serpent is found in Azi or Aji, who received the epithet dahâka, or enemy, and from the union of the two words is formed the modern Zohak, who is slain by Feridoun. [Thraêtana.] It cannot be denied, however, that the Iranian Ahriman is a far more important being than the Brahmanic Vritra. The former has been exalted in a measure corresponding to the dignity of Ormuzd as compared with the Vedic Indra, until from the cloud enemy of the gods (adeva, Gr. ἄθεος) he has become the creator of an evil world peopled by hosts of malignant demons. Thus the myth, as professing to account for the phenomena of the moral world, becomes metaphysical, and is lost in the de-

velopement of Parseeism. This Iranian demonology is seen in the ASMODEUS of the Book of Tobit, and in the dragon whom Christian art represents as crushed beneath the feet, and pierced by the lance of St. George. (Bréal, *Hercule et Cacus*; Muir, *Sanskrit Texts*; Max Müller, *Lectures on Language*, second series.)

Vritrahan. [VRITRA.]

Vulcan. In Latin Mythology, the god of fire. The name is connected by some with the words *fulgere*, to glisten, and *fulgur* and *fulmen*, lightning; by others, with the Sanscrit ulkâ, *a firebrand* or *meteor*. The legends about Vulcan are mere reproductions of the myths which grew up round the name of the Greek god HEPHÆSTUS, with whom the Latin deity was in course of time completely identified.

Vulcanite. Synonymous with EBONITE. A good vulcanite is made by heating to 300° Fahr. for six hours a mixture of two parts of caoutchouc and one part of sulphur. Vulcanite resembles horn in appearance; it is much used for making combs, and being an excellent insulator has been recently proposed as the best material for the covering of telegraph wires.

VULCANITE. A Mineralogical synonym of Pyroxene (Augite) or Volcanic Garnet.

Vulgar Fractions. In Arithmetic, any fraction whose denominator is a power of 10 is termed a *decimal fraction*. [FRACTION.] All others are called *vulgar*.

Vulgate (Lat. vulgata, *for public use*). The name given to the Latin version of the Scriptures in use in the church of Rome; the greater part of which is the composition of St. Jerome. It is decreed by the council of Trent that the Vulgate is to be 'held as authentic,' which, according to the interpretation usually put on the decree by theologians, means not that it is in any way substituted for the originals, but that it contains nothing contrary to true faith and morals. (Milman, *History of Latin Christianity*, book iii. ch. xi.; Hallam, *Literary History*, part i. ch. vi. p. 39.)

Vulpes (Lat.; Ital. volpe, *a fox*, akin to Gr. ἀλώπηξ, Sansc. lôpâça, Eng. *wolf*). This has been made a subgeneric term by those naturalists who so distinguish the foxes from the dogs, jackals, and wolves, to which they consequently restrict the term *Canis*. The grounds for the proposed distinction are chiefly that the form of the pupil of the eye is vertical in the foxes, and circular in the dogs; the lobes of the upper incisor teeth are less distinctly marked than in the dog; the tail of the fox is longer and more bushy; its head broader, and terminated by a narrower and more pointed muzzle; its gait and attitude crouching.

Vulpinite. So called from Vulpino, near Bergamo in Italy, where it is found. An anhydrous sulphate of lime (Anhydrite), containing about 8 per cent. of silica. It is sometimes employed by Italian artists for small statues and other ornamental work, under the name of *marmo bardiglio di Bergamo*.

Vultur (Lat. *a vulture*). The name of a Linnæan genus of diurnal Accipitrine birds, characterised by an elongated beak, curved only at the extremity, and by having a greater or less proportion of the head, and sometimes of the neck, denuded of feathers. To the brief Linnæan phrase descriptive of this genus it may be added, that the power of the claws does not correspond with the bulk of the body. The wings are so long that they are carried in the half-extended state when the vulture walks on the ground. In general, the birds of this group are of a cowardly nature, living on dead carcases and offal; their gullet dilates into a considerable crop, which, when distended with garbage, projects above the furcular bone. When the vulture is gorged with food, a fœtid humour is discharged from the nostrils, and the bird is reduced to a state of stupidity. The vultures of Linnæus are divided into the subgenera *Vultur*, Cuvier; *Cathartes*, Cuvier; *Sarcoramphus*, Cuvier; *Percnopterus*, Cuvier; *Gypaëtus*, Storr.

W

W. A letter found only in the alphabets of modern languages. In form, it resembles two V's, and its English name is derived from the fact of the letter *v* being identical with *u* in the Latin, and in the more early form of the English language. In German, *w* is pronounced like the English *v*; the latter having the sound of *f*. When *w* commences a syllable, it is a consonant; but in all other positions, a vowel.

Wacke. A German Geological term, now rarely used. It originally meant a soft and earthy variety of basalt. [GREYWACKE.] Other metamorphosed rocks of considerable hardness have received the same name.

Wad. A local name, in Derbyshire and the north of England, for Graphite or Plumbago. In Mineralogy, the term is used to denote various mixtures of different oxides of manganese, which cannot be always considered as distinct species or as having a very definite chemical composition. The name has reference to the light forms, resembling *wadding*, assumed by the mineral.

Waders (Ger. waten, Dutch waaden, *to wade*, akin to Lat. vado, and Gr. βαδίζω, *to go*). An order of birds, including those which have long legs naked from above the distal or lower extremity of the tibia downwards. [GRALLATORES.]

Wads (Ger. watte). In Artillery, wads are of four kinds: *junk* [JUNK WADS]; *grummet* [GRUMMET WAD]; *papier-mâché*, being small discs used for closing the fuze holes of

filled common shells and the loading holes of diaphragm shells; and *coal dust*, being serge bags filled with coal dust, and placed inside the 5-lb. cartridges for 8-inch guns, to fill up the chamber.

Wadset. In Scottish Law, a method of mortgaging landed property. It is now obsolete, having been superseded by the *bond and disposition in security*, consisting of a covenant for payment of the debt and a conveyance of the land by way of security, with a power of sale; the practical effect of the whole being much the same as that of an English MORTGAGE, except that the debt constitutes REAL PROPERTY, and not, as in England, PERSONAL PROPERTY of the creditor.

Wafers. Adhesive discs for securing letters or sticking papers together. Common wafers are punched out of a paste made of very fine flour which is pressed between two heated plates of smooth iron. Transparent wafers are made of films of isinglass or gelatine, dried upon plate glass, and punched out of various forms and sizes. Wafers are coloured with various materials, but care should be taken that these are not, as is often the case, of a poisonous nature. The wafer makers are very unwilling to show the process.

Wager (Ger. wagen, *to venture*). In Law, wagers were formerly valid, and might be made subjects of action, unless they were on illegal matters, but now (by stat. 8 & 9 Vict. 109) all contracts by way of gaming or wagering are null and void, nor can a deposit on a wager be recovered from the stakeholder. But this last provision does not apply to subscriptions for prizes at lawful games or pastimes.

Wager of Battle. The usage of deciding a civil suit by battle was common to the jurisprudence of many of the Teutonic tribes which established themselves in the provinces of the Roman empire. It was especially favoured among the Lombards; and there is a celebrated passage in the laws of their king Luitprand, in which, while he recognises the impiety of the custom, he professes his inability to abolish it in consequence of the prejudices of his subjects. In England, battle trial is not mentioned in any Anglo-Saxon laws now extant; and its introduction is therefore attributed to William the Conqueror, although bearing in his laws the Saxon name of *orneste*, probably *earnest.* Sir F. Palgrave (*On the British Commonwealth*, chap. vii.) believes that the Conqueror did no more than confirm a usage already known to the inhabitants of England. He supposes that battle in civil suits was regularly joined in the Anglo-Saxon county courts. Trial by battle, by the English common law, was used in civil cases only, where issue was joined upon a writ of right, in which the tenant pleaded the general issue, viz. that he had more right to hold than the demandant to recover, which he offered to prove by the body of his champion; for in civil actions the combat was not between the parties themselves. The champions were armed with bâtons and targets, and the combat took place before the judges and serjeants of the Court of Common Pleas. The court ought to sit (says Blackstone) by sunrising, and the combatants were bound to fight until the stars appeared in the evening; and if the champion of the tenant could either hold out so long, or obtain the victory, the tenant prevailed in his cause. Victory was obtained either by the death of the champion, or by his pronouncing the horrible word *craven*, which caused to his principal the loss of his land, and legal infamy to himself. The trial by battle was the only mode of deciding a writ of right, until Henry II. introduced the grand appeal or trial by inquest, and gave the tenant his choice between them. The last trial by battle in the Court of Common Pleas was in the 13th Elizabeth, 1571, on which occasion the lists were set up in Tothill-fields (Dyer 301); but in the Court of the County Palatine of Durham there was one in 1638. Trial by battle in criminal cases is explicitly noticed in the laws of the Conqueror. It took place on an *appeal*, when the appellee of felony pleaded not guilty, and declared that he would defend the plea with his body: as in *approvement*, when a party arraigned of treason or felony became an approver by appealing, or accusing his accomplices, the latter might in the same manner demand trial by battle. In this case the combat was between the parties themselves. The last trial by battle awarded in this country was in the case of Lord Reay and Mr. Ramsay, in the 7th of Charles I.; but the king, after having appointed a constable to preside, revoked the commission. In 1818, William Ashford having brought an appeal against Abraham Thornton for the murder of his sister, the appellee waged his battle. Judgment was stayed in consequence of a legal difficulty which arose in the case; and in the following year an Act was passed, by which appeals of treason, felony, and other offences, and trial by battle on writs of right, were abolished. [RATIONALISM.]

Wager of Law. [COMPURGATION.]

Wages (this word may be traced to the same source with the Latin vas, vadis, *surety*, through the Old High German wette, *a pledge*, Gothic vadi, in mediæval Latin wadium or vadium, Ital. gaggio, and Fr. gage). In Political Economy, the payment made for such muscular or nervous labour as possesses a value in exchange. The popular use of the term is somewhat loose. It generally limits the word to mechanical or muscular labour, and to such private revenues as are derived from advances made by capitalists. Such an interpretation, however, is not only vague and unphilosophical, but tends to great errors, which may in the practice of finance become serious wrongs.

All income is derived from wages, profits, rent. Sometimes, however, these three elements are united in the same person, and are not distinguishable except by analysis. In the articles PROFIT and RENT an attempt has been made to show what is the part assignable to each of these elements. It remains to offer some comments on the position occupied by wages.

The rent of land is derived entirely from the natural powers of the soil, or from capital sunk in improvements. The profits of capital are derived either from permanent investments, or from loans made on security which cannot be impugned. If the investment be liable to depreciation, or the security to discredit, a payment is always expected on the ground of risk or hazard. It is plain, however, that such a payment is no part of profit. Capital may be invested in a variety of ways, as in draining land, in constructing railways, in building houses. But capital is equally invested in the education of artizans and of professional persons—of all persons, in short, who live entirely and exclusively on labour; and in so far as the rate of payment made to them is in consideration of the capital invested in such an education, so far is it profit on capital, and not wages. Again, in so far as the payment (after estimating, in a general way, the cost or outlay of capital incurred in physical, mechanical, and intellectual education) is in excess of the rate of profit procurable, on an average, from such an amount of capital invested in a permanent form, so far does the payment tend to replace the capital invested, and to cover the risks involved in such occupations. And if equal capacity for supplying services in demand is attained under less cost, or superior and exceptional capacity is exhibited, the analogy subsisting between natural abilities, whether mental or bodily, and singular fertility in certain soils, is manifest and clear.

The power of obtaining wages invariably therefore implies the outlay of capital in the maintenance and education of the labourer; and the rate of wages will, some risks being estimated, and some machinery for replacing the waste of capital being implied, be therefore relative to the rate of profit. The maintenance of a child in the cheapest and most economical form—that, for instance, in an industrial workhouse school—will represent at the end of ten years, at 5 per cent. compound interest, little less than 100*l.*; and of course, if the age at which the labourer is able to earn his or her living is more protracted, and the cost of maintenance and education larger, the existence of such a person will represent a still larger sum invested as capital, when interpreted from an economical point of view, and liable, because invested in this form, to certain depreciation and numerous risks. Furthermore, the cost of supplying such labour will include not only the particular depreciation and risk to which such an investment is liable, but all losses which premature death and disease induce upon similar employments of capital, distributed over those who survive as efficient labourers. It is not indeed important, for the purpose of analysing the cause of wages, that the charge should be borne by the parents of the child, or that the risks should be incurred by the labourer himself. They may be incurred by third parties, and under the machinery of a poor law they are largely so incurred in the case of common labour. It is only important to observe, that unless this perpetual investment of capital in the supply of labour goes on, the supply would rapidly diminish, rates of wages would rise from deficiency, and rents would fall. It is only because labour is ordinarily in excess of demand, that the true facts as to the economical investment of capital in the maintenance and education of labour are hidden or escape notice. When, as in newly settled countries which possess large tracts of fertile and unoccupied land, population increases rapidly, but not so rapidly as capital, it is seen that the supply of labour is one of the most important forms in which capital may be employed.

A confusion, then, between the income derived from wages—the word being used in the widest sense, to include all labour however rude or however refined—and the profits derived from stock, or rent derived from land, is unphilosophical, and the subjection of both to equal rates of taxation, whether the tax be levied on the consumption of articles necessary to maintain life or on net income, is unfair, because it takes from the profits of capital in the one case, and from capital itself in the other. In taxes at present levied on consumption, few of an absolutely objectionable character exist, the principal of these being the sugar duties and the existing duty on corn; but the wrongs of the income tax are incontestable.

It has been already remarked that the real origin of wages is obscured by the fact that labour is generally in excess of demand. Hence, it is ordinarily related to supply, instead of being valued, as it ultimately must be, by the amount of labour or capital expended in bringing it into existence; in other words, by the cost of production. To this condition, labour, like every other article of value in exchange, except rent, must conform in the end. It will not on the spot where it is produced be remunerated at a higher rate than the costs at which it is produced; it cannot, to be produced at all, fall much below it.

There are always, however, certain circumstances qualifying the rate of wages within certain limits, which do not affect other utilities in an equal degree. The fact that labour is less easily transferred, as a rule, than other objects, tends to depress the rate. This immobility of labour is due partly to factitious causes, partly to personal motives operating on the mass of mankind. The laws which have for so many ages attempted to compel the residence of labourers to given spots are instances of the first set of causes. In feudal times the intimate relations which were supposed to exist between the various classes of society, interpreted of course with greater stringency in the case of the peasant, put a variety of hindrances in the way of migration from place to place. When the labourer possessed, as he generally did, land as the reason of his dependence on the lord, he could not migrate without forfeiting his tenancy. This condition was extended to the lord's dependants, who could not escape from

a particular locality, except by paying a fine. [VILLEIN.] Another cause of the same character was the police exercised in that time. A landless and lordless man was an outlaw, or vagabond, and was generally treated, and probably with justice, as a thief. Again, when in consequence of the great plague of 1348 the price of labour rose enormously, the law attempted, in the interest of landowners, to check migration. An attempt to fix wages at low rates must, in order to have any operation, attempt also to hinder the departure of labour from its customary field of employment. Finally, when labour became in excess of demand, and the law provided that unemployed labour should be maintained, similar checks were put on the voluntary removal of labourers in order to obviate the risk of maintaining extraneous labour. This was the effect, if not the origin, of the law of settling the poor to particular localities, in pursuance of certain acts which were construed to give a special interest or right in a certain place. [SETTLEMENT.] Such causes, when in existence for a time, will be sure to operate on the mobility of labour, even after they have been formally repealed, or practically abandoned.

On the other hand, there are causes which check the natural power of motion possessed by labour, and which are derived from the sympathies of the labourer himself. The love of home, friends, family, and the feelings generally which are the foundation of the feeling of patriotism, are great hindrances to migratory enterprises. Even when the area of occupation is practically unbounded, as it is in newly settled countries, the part of the community which moves to new fields of enterprise is small, and much more frequently derived from immigrants than from native inhabitants; while in older and more fully settled communities, the disposition to emigrate requires to be fostered, and, except under peculiar circumstances, is very imperfectly developed. Great as has been the emigration from England, it is questionable whether it has ever raised the rate of wages even in an infinitesimal degree. As far as can be gathered from the census of the people in 1861, the home migration, i.e. the transit of population from the agricultural to the manufacturing districts, from the country to the town, has been little more than the absorption of the overplus. In such a migration, it is clear that emigration is a secondary process, and that, if the former is ineffectual to raise the rate by scarcity, the latter is still less likely to do so.

But if ordinary causes, and even the clear knowledge that labour will be largely benefited in seeking distant employment, are only scantily operative to raise the rate owing to the general immobility of labour, other causes tend to prevent its depression. Thus, for instance, custom is, in the absence of any great or organic social change, a bar to the operation of those causes which might reduce wages by their own force. It is upon agricultural wages that custom is most effective. Any considerable lowering of the rate, even conjointly with the poor-law relief, would ultimately raise rents, and be of little benefit to the farmer. The farmer has no great motive to reduce wages. He may entertain a conviction that any cheap labour is ineffective; he is certain that no special economy of his own, induced on the cost of production, will remain long to his benefit. Still more powerful is the customary food of the people, below a fair amount of which, as supplied by the earnings of labour, wages will hardly fall. Money wages, and the purchasing power of these money wages, are always higher where the labourer lives on dear food, as wheat, when compared with wages where he is content with a lower food, as oats, maize, or rye. To say that the 'habit of secondary wants' is a check to population, is only another form of stating the fact that labour will not increase, and ultimately will not be supplied, if the customary wants of the labourer are ill provided for. Again, if under any extraordinary circumstances the supply of labour falls far short of the demand, wages may undergo a considerable rise, and this rise may be permanent; i.e. the mass of the community will not accept lower wages, and will emigrate or abstain from marriage, rather than run the risk of diminished labour payments. Such a great exaltation of the wages of labour took place after the great plague of 1348 [LABOURERS, STATUTE OF], and similarly a great depression of the wages of labour followed on the currency schemes of Henry VIII. in 1543.

But though the rate of wages is permanently affected by the kind of food ordinarily consumed by the labourer, it is not affected by the market price of this food. Wages are not necessarily high when food is dear, low when food is cheap. The cause of cheap food is quite distinct from the cause of low wages, the former depending on the plenty of the seasons and the abundance of fertile land, the latter on the density of population. In countries where food is cheapest, while the countries themselves are rising in opulence, wages are highest. The fact that food and labour prices depend on different causes is a little obscured in this country by the operation of the poor laws, for they who contribute the largest amount to the poor rate find it better to increase the wages of their labourers than to pay the money which they might devote to this end to a common fund from which they could derive no benefit, or only an indirect benefit. [PAUPERISM; POOR LAWS; POPULATION.]

Attempts to raise the rate of wages by a machinery adopted by labourers themselves have been already commented on. [TRADES' UNION.]

For the effect induced upon wages by the great plague of the fourteenth century, see Rogers' *History of Agriculture and Prices*; for information as to the rates of wages in Europe, see La Play, *Les Ouvriers Européens*.

Wagite. A concretionary hydrated silicate of zinc, from Nijni-Jagurt in the Ural, of a colour varying from pale blue to green. Named in honour of Waga, the naturalist, of Warsaw.

Wagnerite. A very rare mineral, named after Von Wagner. It is a phosphate of magnesia associated with fluoride of magnesium, and is found in the valley of Hollengraben, near Salzburg, in Austria.

Wahabees or **Wahabys.** A Mussulman sect, of which the founder was a learned Arabian, named Abd el Wahâb, who became persuaded of the corruption, both of doctrine and practice, prevalent among the professors of Islam, especially the Turks. His daughter married Mohammed Ibn Saoûd, the principal person of the town of Derayeh, who became his first convert and leader of the sect about 1760. Like the original prophet of their faith, Saoûd and his followers propagated their doctrines at once by persuasion and arms. Abd el Aziz and Ibn Saoûd, the son and grandson of the first Saoûd, carried their arms to the utmost extremities of Arabia, and, conformably with the old Mohammedan principle, established a spiritual and temporal leadership united in their persons. The Bedouins, or wandering tribes, formed the bulk of their converts. They acknowledged the Koran and the Sunne, or orthodox tradition, and they professed adherence to the liberal tenets of both; but they accused the other Mohammedans of an idolatrous veneration for the Prophet and other saints, and denied the intercession of saints altogether. Like the early Protestants of Europe, their favourite taste was the destruction of the cupolas and tombs of saints. To this the mob of Wahabees added a strong aversion to the rich dress of the Turks, and to the practice of smoking tobacco, which had been prohibited by Abd el Wahâb much on the same bold principle which had induced Mohammed to condemn the use of wine. The province of Nedjd became the chief seat of the Wahabee power. Under the last Saoûd (a very handsome man, whom the Arabs called Abou Showareb, or the Father of Mustachios), it reached its greatest extent. Like the early caliphs, he administered justice in person to great part of Arabia. The Wahabees, in the first twenty years of this century, extended their plundering expeditions to Syria, Irak, and Mesopotamia. In 1803 they took Mekka, and soon conquered the Hidjaz. In 1809 Mehemet Ali, the pasha of Egypt, began hostilities in Arabia; and in 1812 the Hidjaz was reconquered. Saoûd died in 1814, and was succeeded in his political and religious authority by his son Abdallah, under whom the Wahabees were subdued by the lieutenants of Mehemet Ali. But the Egyptians were unable to maintain the supremacy which they had obtained. Gradually the Wahabees regained their influence in the central parts of Arabia, and the Egyptians and Turks were driven back to the Hidjaz. But for many years no authentic information respecting the condition of this remarkable sect reached Europe. The first detailed intelligence about them was conveyed in Palgrave's *Travels in Central Arabia*, in 1865. That remarkable explorer found them established, under their blind Ameer, Feyzul, at Riadh, the modern capital of Nejd, maintaining a theocratic government of the most austere kind, and controlling by their arms and their example the chiefs of great part of the peninsula. His account was in the main confirmed by that of Lieut.-Col. Pelly, who visited Riadh as an agent of the British government of India. Their power seems still on the increase, their chiefs having of late obtained paramount influence in Oman and along the shores of the Persian Gulf, while numerous fanatical Mohammedan bodies, congenial in spirit with the Wahabees if not actually allied to them, have become prominent even as far as the borders of British India. (Burckhardt's *Travels in Arabia*; Burckhardt's *Notes for a History of the Bedouins and Wahabys*, 1830.)

Wahl Capitulation (Ger. wahl, *election*). In Modern History, the covenant entered into by an emperor of Germany with his electors on the occasion of election; by which he obliged himself to respect the liberties of the empire and of the diet, to surrender no portion of the empire, to preserve in vigour the stipulations of the peace of Westphalia, &c.

Waif (from the Saxon wafian, *to abandon*). In Law, goods stolen and abandoned by the felon, were so termed, and were forfeited to the king, or lord of the manor having the franchise of waif; but if the owner made fresh pursuit after the felon and apprehended him, or gave evidence whereby he was convicted, within a year and a day, he was entitled to restitution.

Wainamoinen, Epic of. This poem entitled Kalewala, and comprising a theogony not unlike that which bears the name of Orpheus, has been recently collected from the Finns, among whom it had been preserved wholly by oral tradition. It equals the *Iliad* in length and completeness; and in Professor Max Müller's opinion possesses merits which admit of comparison with those of the *Iliad.* It is further noteworthy as retaining the agglutinative type of languages, although at first sight it may be thought to have entered the inflectional stage which characterises the Greek and Sanscrit. (*Lect. on Language*, first series, ix.)

Wainscot. In Architecture, the framed lining in panels with which a wall is faced.

Waist (Welsh gwâsg). The part of the upper deck between the fore and main mast.

Waits (probably akin to Ger. wacht, *a watching* or *waking*). The popular name for the music played in our streets on the nights of the Christmas holidays. (*Archæol.* vol. ii. p. 66.)

Waiver (from *waif*). In Law, a term used to signify a party's declining or refusing to accept or to avail himself of something; as an estate, or of irregularities in legal proceedings.

Waiwode. In the Turkish empire, the governor of a small province or town.

Wake (Ger. wachen, Lat. vigilare, *to watch*). In popular usage, this word has the same meaning as *vigil.* The *wake* or *revel* of country parishes was, originally, the day of the week on which the church had been dedicated; afterwards, the day of the year. In 1536, an act of

convocation appointed that the wake should be held in every parish on the same day, viz. the first Sunday in October; but it was disregarded. Wakes are expressly mentioned in the *Book of Sports* of Charles I. among the feasts which should be observed. The wake appears to have been also held on the Sunday after the day of dedication; or, more usually, the day of the saint to whom the church was dedicated. In Ireland, it is called the *patron day*. (Brand's *Popular Antiquities*.)

WAKE. The track of a ship which she leaves in the water. A vessel directly astern of another is said to be in her wake.

Walchowite. A mineral resin, met with in rounded translucent masses, in the brown coal of Walchow, in Moravia.

Waldenses. In Ecclesiastical History, a religious sect, said to have derived their name from Peter Waldo, a merchant of Lyons, who preached what he regarded as the pure doctrine of the Scriptures about 1180. Historians have confounded them, on the one hand, with the VAUDOIS, who appear, although their history is involved in much obscurity, to be an older and separate people; and, on the other, with the Albigenses. They seem to have rejected an established succession of the priesthood, and the high Catholic doctrine of the sacraments; and are said in addition to have protested against oaths, warfare, lawsuits, and is obscure; and it may be said of them, as well as of other sects of the day, that they had little of the elements of permanence, the same opinions being continually promulgated afresh by new reformers, and then receiving new denominations. [ALBIGENSES; PETROBRUSIANS; VAUDOIS.] The reader may consult Milner's *Eccl. Hist.* for the most favourable view of these and similar sectaries; and, among many other authorities, Faber, *Churches of the Waldenses and Albigenses*; Mosheim, cent. 12; Jones, *Hist. of the Waldenses*; Milman, *Hist. of Latin Christianity*, bk. ix. ch. viii.; *Archæologia*, vol. ix.

Wales. Lines of planking in a ship's sides and quarters, thicker than the other strakes of plank. They occur at points where extra strength or curvature is required.

Wall (A.-Sax. weal, Lat. vallum). In Architecture, a body of stone, bricks, or other materials, enclosing a space, or carrying superincumbent weights, or serving both these purposes.

WALL. In Horticulture, a fixed structure for the purpose of improving the climate of plants by shelter, by supplying heat, and by exposing them to the influence of the sun.

Wall Eye. The popular name for the disease called GLAUCOMA.

Wall Knot. [KNOTS.]

Wall Plate. In Architecture, a piece of timber lying on a wall, on which girders, joists, and other timbers rest.

Wallflower. The popular name of one of our sweetest spring flowers, called by botanists *Cheiranthus Cheiri*.

Wallis' Theorem. Under this name the following remarkable expression for the ratio π of the circumference to the diameter of a circle is frequently referred to:—

$$\frac{\pi}{2}=\frac{2^2 \,.\, 4^2 \,.\, 6^2 \,.\, 8^2 \,.\, .}{3^2 \,.\, 5^2 \,.\, 7^2 \,.\, 9^2 \,.\, .} \text{ ad infinitum.}$$

John Wallis, the discoverer of this theorem, was born in 1616. His *Opera Mathematica* were published at Oxford in 1699.

Wallower. In Machinery, this term is used synonymously with *lantern* or *trundle*. [LANTERN WHEEL.]

Walmstedite. A Mineralogical synonym of Breunnerite (native carbonate of magnesia), after the Swedish chemist Walmsted.

Walnut (A.-Sax. wealh-hnut, Ger. wälsche nuss: wälsch in German means originally *a foreigner*; the word was applied especially to the Italians, and hence *walnut* means the *foreign* or *Italian nut*: Max Müller, *Lect. on Language*, second series, viii.). The fruit of the *Juglans regia*, a noble tree, which is also valued for its timber. Besides being eaten when ripe, walnuts are pickled while in the green soft state.

Walpurgis Night. The night of the festival of Walburga, niece of Boniface, the apostle of the Germans. This feast (May 1) is a common day in Germany, like Lady-day in England, for the commencement of leases, &c. It is also known as the day on the eve of which, according to popular superstition, the great witch festival is held on the summit of the Brocken, in the Harz Mountains.

Waltz (Ger. walzen). The name of the German national dance, and also of the species of music by which it is accompanied. Bohemia is said to be the original home of the waltz, whence it soon spread into other parts of Germany, and all over the Continent; and within the last few years it has become naturalised in England.

Wampee. The Chinese name for the fruits of *Cookia punctata*, highly esteemed in China and the Indian Archipelago.

Wampum. The American Indian name for shells used as money, or as a medium of commerce. These shells are run on a string, which is used as a belt.

Wapentake (A.-Sax. wæpentac). A territorial division in use among the Danish inhabitants of England: from wapen, *a weapon*. Yorkshire is subdivided into wapentakes instead of hundreds.

Wapiti. [ELK.]

War (A.-Sax. wær, of which the French form is guerre). In International Law, war is said to be *public* when it is a contest, by force, between independent sovereign states. A civil war is regarded by Grotius as *mixed* in its nature; being, according to him, public on the side of the established government, and private on that of the portion of the people resisting its authority. Public war is said to be perfect when one whole nation is at war with another, and all the members of each are authorised to commit hostilities mutually, subject only to the general laws of war. An *imperfect war* is limited as to persons, places, and things: to which class are referred by some

the hostilities of the United States against France in 1798; the hostilities between England, France, Russia, and Turkey, in 1827; and, if the usages of civilised nations could well be cited in such a case, our hostilities in China.

Formal declarations of war are now out of use: the latest example is said to be that by France against Spain, at Brussels, in 1635, which was announced by heralds. War is now usually preceded by the publication of what is termed a MANIFESTO; and the permission of REPRISALS is usually the last step short of actual hostilities and preceding them. The immediate effect of the commencement of hostilities would appear to be, on principle, the liability of all property belonging to subjects of one of the belligerent parties within the dominions of the other to seizure and confiscation; but many exceptions have been introduced by the practice of civilised states. (Grotius, *De Jure Bel. et Pac.* lib. iii.; Vattel, lib. ii.; Phillimore *On International Law*, vol. iii. ch. iv.) In former times it has been the regular practice in Great Britain to seize and condemn, as droits of Admiralty, property of the enemy found in our ports at the commencement of hostilities; but at the commencement of the Russian war, in 1854, the enemy's merchant shipping were allowed six weeks to depart in, and various other changes and relaxations were made. Trade, and every species of contract between subjects of belligerent states, is in general unlawful, although often authorised for particular times and purposes. Subjects of hostile states, *domiciled* in the enemy's country, have been held liable to reprisals; but not, it is said, mere travellers or temporary sojourners, though Napoleon on the renewal of hostilities in 1803 seized all English subjects then sojourning in France. In 1854, Russia, France, and England respectively accorded protection to resident enemy's subjects.

The rights of war are such as arise in times of hostilities: 1. Between enemies; 2. Between neutrals. As between enemies, it is a general law that subjects of a hostile state who are not in arms, or who have submitted, may not be slain. The killing of prisoners is justifiable only in very extreme cases. The usage of exchanging prisoners is now general, but was firmly established only in the seventeenth century; and it is not now considered obligatory. As to property, that belonging to the government of the vanquished nation belongs to the victorious state, wherever it is found; but private rights are unaffected by conquest, with the remarkable exception of private property when at sea, which is by general usage held lawful prize. The immunity of private property on land, however, is of a qualified nature only; generals have frequently laid waste hostile territory, as far as convenient for military operations and sometimes without this excuse, and contribution of money, food, &c., for the support of an advancing army and other military purposes, have also been required, as was done by Napoleon, and again by Prussia in her war with Austria in 1866. Acts of hostility are lawful, according to the modern usage, only when committed by those who are authorised by the express or implied command of the state; such as the regularly commissioned military and naval forces of the nation and all others called out by the government in its defence, as well as persons spontaneously defending themselves in case of necessity. Irregular bands of marauders are therefore denied the rights of war, and are liable to be treated as banditti; but this distinction is generally observed only so far as suits the belligerent's purpose. For private citizens taking up arms, although in obedience to proclamations, are constantly liable to be treated as marauders; as by the French in the Peninsular War, and in many other cases. For the rights of war as to neutrals, see NEUTRALITY. (*Oxford Essays* 1856, 'Growth and Usages of War;' Kent *On International Law.*)

War, Art of. In its simplest form, as seen among savage tribes, war always involves some artifice in addition to the mere open application of brute force. To steal unperceived upon the enemy, and attack him unprepared with the best weapons at command, is the first step in the developement of the military art, and as, from the earliest times, the passions of men have given rise to war, the desire of success has led to the improvement of this art, side by side with the progress of the other arts.

For some notice of the ancient systems of warfare, the limits of this work compel us to content ourselves with referring the reader to the articles HASTATI, HOPLITES, LEGION, MERCENARIES, PELTASTS, PHALANX, PRINCIPES, TRIARII, TURMA, VELITES; and also to Guischardt's *Mémoires Militaires sur les Grecs et les Romains*; Guibert's *Essai Général des Tactiques*; and Dr. Smith's *Dict. of Greek and Roman Antiquities*, art. 'Exercitus.'

When the Western Empire was overthrown, and the whole of Europe overrun by wild hordes of barbarians, each man was allowed a share of the conquered lands as a reward of his past military service, in return for which he was bound to future service. From this practice sprang the feudal system, and, during its continuance, war, as an art, seems to have become almost extinct. Petty wars between small rival chiefs, with incursions into neighbouring territories, formed the only military exploits of the earlier ages of feudalism. Then came the Crusades, in which army after army, ignorant of military science, and utterly deficient in organisation, melted away through the lack of unity, concert, and design. The same want of organisation is visible throughout all the wars of the period. The armies of the time seem to have been only an assemblage of knights and barons with their retainers, living on the territory under invasion, making desultory attacks on castles, or occasionally drawing up their motley forces in order of battle, and then charging in a grand mêlée. Strategy and tactics, as sciences, did not exist. Often utterly ignorant of the enemy's position, and

seldom knowing anything of the features of the country in which they were campaigning, the opposing commanders either agreed upon the place of battle, or left it entirely to chance. The chronicles of Froissart furnish many amusing instances illustrating this state of affairs. The only attempt at formation seems to have been to place the archers in front, to open the battle, the men-at-arms afterwards dashing into the thick of the fight with swords and axes.

No attempt was made to supply an army with provisions for a long campaign, from dépôts at a safe distance. Such a task was beyond the means of any feudal monarch; he could do no more than raise taxes and loans to set the army in motion, and then leave the war to maintain itself. But in course of time the power of the nobility declined, and in some cases became extinct; in others the king, by levying taxes on the people, surrounded himself with a standing army of trained and disciplined troops. Then arose a competition in warlike efficiency, heightened by the recent invention of gunpowder. For a long time the application of this invention had made but slow progress; but, in the time of Charles the Bold, field artillery had attained to considerable value; and the standing army of this sovereign proved itself so vastly superior to the feudal levies, that others soon followed his example, and standing armies of paid troops became the only forces employed.

The great wars of the Netherlanders with Spain at the latter part of the sixteenth century brought about great changes in organisation and tactics, but the method of fighting in deep columns or masses characteristic of all the previous periods was still retained. Then came the Thirty Years' War, in which Gustavus Adolphus inaugurated a new system of tactics, and fought with lines of infantry six deep against the solid masses, thirty deep, of Tilly and Wallenstein. He also formed his cavalry in three ranks only, and associated them with light guns.

After the Thirty Years' War came the wars of the French in Italy, in Germany, and the Netherlands, lasting for a century till the peace of Westphalia in 1738. At this time the efficiency of artillery, and the improved state of the roads and of transport, rendering the movement of guns comparatively easy, caused the art of fortification to be much improved. From the time of Albert Dürer, improved methods of fortifying towns had been applied by successive engineers; but the genius of Vauban during the wars of Louis XIV. increased the resisting power of fortresses to a marvellous extent. An advancing army, dependent upon its communications for supplies, could not safely pass by one of these, and thus the wars of Louis XIV. were but a series of sieges, and Marlborough's sieges far outnumber his battles.

During all this time the military machine was growing more manageable, and Frederick the Great of Prussia in his Silesian wars, taking advantage of the great mobility of the army, which had been drilled to perfection by his father, preferred to *mask* or observe fortresses with a small detachment of troops, and fall with his rapidly moving troops upon the slow bodies of the enemy.

Under Frederick the Great, the army was an aggregate of battalions; when assembled in the field it was itself the integer, and any detachment a fragment. The great success of this commander lay in watching his enemy, and, from the flexibility of his army, taking advantage of any error or unguarded movements; then falling rapidly on them, and especially applying his great tactical stroke, of placing his line obliquely across the extremity of his adversary's line within striking distance, he ruined them before their slow masses had time to change front to oppose him.

The Prussian plan was speedily adopted by the other nations of Europe, but it was left to the Emperor Napoleon to introduce that system of organisation and tactics into armies, by means of which he overthrew the troops trained upon Frederick's system, possessing in his own army the superior mobility and mutual support of all arms, which had previously belonged to Frederick.

In the first wars of Revolutionary France, many small bodies of troops, acting independently, were spread along her whole frontier, and were made complete in all arms, and trained to manœuvre in concert; but there was want of unity in their movements, and this unity was only attained when Napoleon, in supreme command in 1804–5, abstracted the great mass of the cavalry from the divisions, and united the divisions into corps under a marshal or lieutenant-general, each corps being sufficient to act independently, and complete in all arms. He then held the reserve of chosen troops in his own hand, ready for the decisive blow. Possessing also, in the French, troops of more intelligence than precision of training, he employed them as skirmishers, thus commencing the employment of light infantry.

We have thus briefly traced the history of the art of war, down to the present time, when arms of precision have been introduced; and we now propose to sketch the principles by which the operations of war are guided.

An army, as now constituted, is a gigantic machine, composed in part of disciplined soldiery, divided according to the different arms, and commanded by a hierarchy of officers, and partly of a mass of necessary appurtenances required for the efficiency of the rest, such as food, ammunition, shelter, medicine, and clothing. Such an instrument must be constantly receiving repairs, and the stream of supplies to it must be unceasing, both of men and material. It must, then, as it advances into an enemy's country, or protects some portion of its own, have some fixed source from which to draw these supplies. This source is called the *base of operations*, and may consist of a frontier line, a group of fortresses, a harbour on the sea coast, or other position. Here the great maga-

zines must be so protected as to be safe from danger, and to afford a secure starting-point for an army, and a safe shelter if a retreat should become necessary. Thus, if France were at war with Germany, she would find in the Rhine, strengthened by fortresses, such a base of operations; if with Italy, she would collect her supplies behind the barrier of the Alps.

If an army lacks a secure base of operations, it is at any time liable to be obliged to separate in order to subsist, and then all unity and concert is lost. An instance of the evils of operating without such a source of supply is afforded by the duke of Wellington's correspondence after the battle of Talavera. Placing reliance on the promises of the Spanish government, he left his dépôts in Portugal, and marched into Spain. There he fought and won the battle of Talavera. But, though victorious, he could obtain neither food nor forage for his army, and was compelled to retrace his steps to Portugal, thus losing a brilliant opportunity of striking a blow upon Soult at Placencia, or upon Mortier in the centre.

It is necessary, however, not only to possess such a base, but to keep up the connection with it, for evidently if the connection be destroyed, the advantages of the base are lost. An army must, then, at the risk of danger and ruin in case of failure, so dispose its forces, that on every advance or retiring movement it may secure and hold fast the line connecting it with its base, which is called the *line of communication*. 'Two armies,' says Colonel Hamley, 'are not like two fencers in an arena, who may shift their ground to all points of the compass, but rather resemble two swordsmen on a narrow plank which overhangs an abyss, where each has to think, not only of giving and parrying thrusts, but of keeping his footing under penalty of destruction.'

This, then, may be laid down as the leading principle of war, a departure from which may involve ruin.

In order that the enormous stream of supplies may be uninterrupted, good high roads, such as are generally only the main arteries of a country, are indispensably necessary. The fatal results of having none but bad roads to connect an army with its base, is shown by our own Crimean experience, where seven miles of soft soil caused such fearful difficulties; and again in McClellan's despatches, the same fact is proved as regards the Yorktown campaign. Besides this, good roads enable troops to move so much faster, and with so much less fatigue, that their quality must be taken into consideration in forming any plan. That armies move sometimes on bad roads is true; but such movements as that of Napoleon over the St. Bernard, and Wellington's pursuit of the French in 1813, are only of brief duration, and undertaken only when a new and better communication with the base is open at their conclusion.

We must thus think of an army, not as free to move anywhere in the theatre of war, but as dependent on a line, which must be a good road, connecting it with certain secure magazines in rear. Next, an army must be considered as moving not only on one main road, but distributed in parts upon several roads. An army acting on the defensive will have to hold all those lines by which an invader could advance, in order to check his progress at any point, till troops can be collected in numbers sufficient to repel him. Thus it must be spread out over many roads, radiating from the point which it has to cover. An invading army must march by many roads, or the column would be of such a length that its head and each succeeding portion might be destroyed before the troops in rear could arrive to its aid.

Approximately, 30,000 infantry occupy about 5 miles on the road, 60 guns about 2½ miles, 8,000 cavalry, in column of fours, about 3½ miles, irrespective of intervals between the columns, of losses of distance, and of stores. McClellan, speaking of his advance from Washington, remarks, 'If I had marched the entire army (about 100,000 men) in one column along the banks of the river instead of upon five different parallel roads, it would have extended about 50 miles.'

The more good parallel roads, therefore, that an army can find, the more rapidly can it assemble in fighting order. But good lateral communications between the roads are essential, or one part of an army may witness the defeat of another portion, without being able to assist, as in 1796, where the Austrians advancing on both sides of the lake of Garda, were beaten in succession.

An army advancing in such a manner must not only, as it advances a long distance, protect the magazines at its base, and the communications to them, but must establish magazines on these lines. In an enemy's country, the commander will at once obtain by requisition supplies of food and stores, and will further collect in magazines the surplus resources, so as to reserve for the hour of need the supplies which he already possesses. He will place these magazines on several radii of communication, and as much as possible at the junctions of roads, always covering them with his army.

Thus the most important points to be observed in order to follow the operations of a campaign consist of: (1) the bases on which the contending armies respectively rely for supplies of men and material, (2) the main roads by which they approach each other as they advance from their bases, (3) the positions of their magazines on those roads, and (4) the positions of the fronts of the armies as regards their lines of communication, in all their changes.

Before beginning hostilities, one party will generally resolve upon assuming the offensive, the other the defensive. Occasionally, as in the Italian campaign of 1849, both parties simultaneously advance; but generally one will resolve upon standing on the defensive, either

for political reasons, as the Confederate States in the late American war; or for geographical reasons, as when Wellington held the impregnable frontier of Portugal in 1812 and 1813; or from its relative weakness, as with Denmark in 1864. The defensive army must, as already shown, be spread over a considerable space; it is easily supplied and if forced back retires towards its magazines; but these advantages are more than counterbalanced by those possessed by an offensive army, which can concentrate behind its frontier, and so descend in force on any point of the defender's line, the defender's movements being from that moment dependent on those of the attacking party. The defender must either oppose the enemy with smaller forces at first, or lose territory in order to fall back and concentrate. On the other hand, offensive war demands great resources; and the invader, advancing into an enemy's country, exposes a long line of communication to attack. But the balance of advantage generally remains with the army possessing the advantage called by military writers the *initiative*.

In assuming the initiative, it is necessary to select an object to be gained by the campaign; and since to occupy a portion of country is of little avail, the end aimed at is generally the occupation of an enemy's capital. It paralyses a country's trade, and is ruinous. But to be able to hold the capital is as necessary as to occupy it; and, for this purpose, the enemy's armies must be defeated.

Occasionally, as in the case of Sebastopol, some other town assumes a peculiar importance; but most commonly the possession of the capital is the desired end. It was so with Napoleon in his Austrian campaigns; with the Federals who operated against Richmond throughout the American war; and with the Prussians in their recent advance into Austrian territory.

Having decided upon the *objective*, as it is termed by military writers, the invading general must select the portion of country in which he intends to operate, i. e. the *theatre of war*. The convenience of different bases, the position of the enemy's forces, the roads, the proximity to the object, and the nature of the country, must all be considered. Not unfrequently political considerations complicate the problem. The necessity of covering the territory of allies, as was often the case in the Austrian wars against Napoleon, and with the Prussians in the campaign of Jena; or the necessity of guarding against a possible attack on a flank from a power whose intentions are doubtful, as was our case in the Russian war, when the Austrian course was uncertain, may compel a certain theatre to be chosen. It is here that a military autocrat, combining political and military power, possesses great advantages, in imparting unity of design to a campaign.

But the impulse and direction having been given to a campaign, we will suppose the formation of the military plans to be left in the hands of the general who is intrusted with their execution. The art of war is commonly divided into *strategy* and *tactics*. Strategy is the movement of an army in the theatre of war, and merges into tactics on the field of battle. All operations must ultimately rely for success on power of fighting; but strategy should so conduct an army as to give it a relative advantage when the collision occurs. If two armies advance straight upon each other face to face, as at Solferino, force and tactical skill must decide the day; but if one army has been so placed as to compel the other to fight in a disadvantageous position, the object of the strategist has been obtained. A general must consider how to increase the *probabilities of victory*, and also how to insure the most important *consequences from victory*. Two armies may be so placed that the chances of victory are equal, but the result of defeat to one may be the loss of its communications, and consequent ruin; while the other, if beaten, can retreat along its proper line. It is needless to say what an advantage the latter army possesses, and with what increased confidence it will fight. On the other hand, two armies may be equally sure of their communications, but one may be scattered, the other concentrated. Here, again, the general of the latter army has attained a strategical advantage. To combine both advantages is the triumph of strategy.

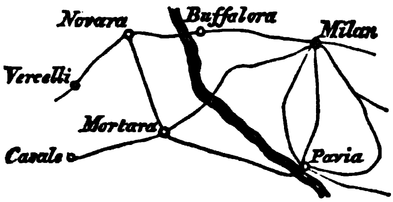
From the necessity of preserving a safe line of communications, it is evident that the great objects of a commander will be, while keeping his own communications guarded, either (1) *to menace or assail the enemy's communications* so as to force him from off his line and base; or (2) *to fall directly on the communications which connect the parts of his army*, and so disintegrate it and destroy it piecemeal, *by bringing superior concentrations on particular points of his front*. Of each of these we will speak briefly.

The way to menace an enemy's communications, and to push him off them, is so to manœuvre as to compel him to form up his army parallel to the line of communication, and in this position to accept battle. For when thus placed, his retreat will not cover his communications, but be at right angles to them; and his communications being thus seized, his army will be cut from its base. If one of two armies is operating on a front perpendicular to its line of communications, while the other is in the position described with *its front formed to a flank*, the advantage is entirely with the former; neither does it matter whether the armies are operating with extended fronts, or concentrated; nor if the front is extended, and the space between wanting in defensible positions, is the distance of the front so formed to a flank from its line of communications of any great importance.

But unless the commander thus manœuvring should succeed when the decisive conflict is fought, he will gain nothing by his strategy. Thus Marmont, in 1812, forced Wellington

to accept battle at Salamanca in this position; but Wellington won the battle, and Marmont reaped no success from his skilful movements. On the other hand, when, in the campaign of 1849, the Austrians under Radetzky, advancing from Pavia through Mortara, forced the Sardinian army under Chzarnowsky to form front at Novara parallel to its communication

Fig. 1.



with its base through Vercelli, the Sardinians, defeated at all points, were pushed off the Vercelli road, and pursued northwards by the Austrians. The result was the abdication of the Sardinian king, and a peace in favour of Austria.

Sometimes it may happen that both armies may form front to their flanks, either from confidence of the issue of a battle on both sides, or for other reasons. It will almost invariably be found, that when two armies are manœuvring against each other's communications, that army whose communications are most immediately threatened will abandon the initiative, and conform to the movement of the adversary. It was so in the campaign of Novara, already cited, where the Sardinian army was striking at Milan, when it felt Radetzky's grip closing on its communications, and at once turned to meet him. It was so also in 1806, when the Prussians, intending to fall on the centre of the line of the Maine and cut off the French, found the latter advancing to intercept their communications with the Elbe. The battle of Jena was fought by both armies fronting to their flanks; and the decisive defeat which the Prussians sustained drove them from their line, and compelled them to retreat in different directions, till ultimately their ruin was completed by the successive defeat of all the portions of their army, and the capture of their fortresses.

Again, the conformation of a base may enable the army possessing it to force its enemy to form front to a flank, as was notably the case when, in 1800, the French possessed the angular base formed by the Rhine in its course from Schaffhausen, by Basle, the point of the angle, to Düsseldorf. This was due to the unscrupulous seizure of Switzerland by Napoleon. The Austrians, whose main body was concentrated about the sources of the Danube, were forced by Moreau, advancing from the south, to form front parallel to their line of communications along the Danube; and, though not signally defeated, they lost the whole of the Black Forest.

Thus it appears that, by taking advantage of the direction of the roads in the theatre for his manœuvres, as at Novara and Salamanca, or by a prompt assumption of the initiative, as at Jena, or by aid of the configuration of the frontier line, a skilful commander may force his enemy to form front to a flank.

But there are cases where a general, having succeeded so far in his manœuvres, has not been content with this, but has thrown his army across the line of his enemy's retreat. This was twice done by Napoleon, at Marengo and at Ulm, and once by Moreau in 1800 on the Danube. In making such a movement, an army must, however, form front either to its rear or to a flank, and so far be in danger. In that case the adversary may reverse the position.

Should the connection of an army with its base be by one road only, it has no choice, if that connection be intercepted, but to cut its way through. Generally, however, there will remain to it two other alternatives, viz. to attempt, by a march to the other flank, to evade a collision, or to march to one flank across the communications of the intercepting force. Of these three alternatives, if it choose the first, it may, by a victory, retrieve all; but a defeat is ruin. If it choose the second, it abandons territory without a blow. If it choose the last, it may, by seizing the enemy's communications, reverse the position; and this is generally the best course to pursue. The first thing for the commander of the army thus intercepted must be to concentrate his forces; the next, to move promptly with his entire army against the communications of the intercepting force. Should he succeed, he may retrieve the campaign. Thus if Melas, in 1800, had been more prompt in his movements, and if Mack, in 1805, had struck boldly at Napoleon's communications towards Nuremberg, much disaster might have been saved to each.

We will now pass on to those operations which have to do with the fronts of opposing armies, but not specially with their communications with the bases. It has already been shown, that troops must, in almost every case, move in long columns on roads. When in this formation, only the heads of the columns can be immediately deployed for action; and so, generally, the march of a force may be delayed and checked for a short time by a small force deployed in order of battle, which may be only a little superior to the heads of the advancing columns.

This is one of the most important facts in strategy; and, if skilfully applied, is invaluable to the commander. A retarding force should be drawn up in such a manner that the advancing troops cannot tell how small it is; they will pause to reconnoitre, and to deploy troops sufficient to be sure of success. And here the skill of the officer in command of the retarding force will be proved. He must occupy his ground to the last moment, so as to retard the advancing enemy as long as possible, but must retire when outnumbered in line, without fighting

a general action, and at the earliest opportunity he must repeat the manœuvre. In this way he may gain for the army from which he is detached most valuable time to prepare for action. It was thus that Ziethen retarded Napoleon's march on June 15, 1815, and by his defence of the several positions of the Sambre, Gosselies, Gilly, and Lambusart, delayed two columns, one 45,000, the other 64,000 strong, so that from morning till nightfall they advanced only four or five miles, although Ziethen himself had only two brigades, each about 8,000 strong.

Again, in following up a retreating army, a small force may often press upon the rear of a large force, for the troops which have been beaten will be disorganised, and their commander will not know how large the pursuing force may be. If, finding out the pursuer's weakness, he should turn, the pursuer will at once take up the part of a retiring and retarding force.

Thus we may assume that part of an army may, in this manner, *occupy* or *contain* a superior force of the enemy, who is advancing, and that a beaten army may be for a time pursued by an inferior force; and one other point scarcely needs demonstration, viz. that the course to be taken by parts of an army which have been separately defeated is to retreat in order to recombine.

Bearing in mind these points, we are prepared to consider those problems which arise where it is impossible, from geographical considerations, for one commander to strike at the communications with its base of the opposite force, without exposing his own communications to similar or greater risk. Such conditions must evidently frequently occur, and opportunities must then be sought in the relations which the fronts of the hostile armies bear to each other. The front of an army being, as we have shown, necessarily divided, opportunities must occur for pushing into the intervals of an enemy's front, and separating its parts. It was thus that Napoleon, in 1796 (the first campaign of his extraordinary career), broke in between the Sardinian army under Colli and the Austrian army under Beaulieu, and separated them; then leaving a small force to *contain* Beaulieu, he threw his whole weight against the Sardinians, and having forced them to a peace which gave him the fortresses of Piedmont, with the Mont Cenis route to France for future operations, turned his whole army upon Beaulieu, and forced him back across the Po.

Thus again, in 1809, he was engaged with the Archduke Charles advancing from the Inn to the Danube in strength equal to his own, and in comparatively close array; but he interposed the main French army between the parts of the Austrian front at Rohr, left Davoust with an inferior force to contain the Austrian right wing, and threw his whole force against the left wing, which he defeated; then detaching a force sufficient to pursue the beaten corps towards Vienna, he concentrated on his left for a blow at the Austrian right wing, which he defeated at Eckmühl, driving it northwards through Ratisbon; then again turning his main force, he pursued the left wing, and pushing out the Austrian garrison, occupied Vienna.

In these operations we see the immense advantage gained by concentrating an army between two divided portions of an enemy. 1. All communication between the divided parts is checked, and combination becomes impossible. 2. Either part of the separated army may find itself exposed to the blows of the full force of its antagonist, minus a detachment left to contain the other part. 3. By alternating such blows, the assailant may continue both to weaken his antagonist and to interpose between the parts. Under these circumstances the best course for the divided army will be to retreat for reunion, retarding the enemy on both lines; for, until reunited, it will be in no position to retaliate upon the assailant's communications, or to attack him in front.

But it follows, as a matter of course, that a force thus interposing itself between two parts of an enemy *must be strong enough to beat either part, after leaving a detachment to contain the other part*; otherwise it cannot expect success.

If an originally combined force is placed in such peril by its front being pierced, manifestly two independent armies, possessing no preconcerted plan of action in the event of separation, are in even a worse case if divided; and thus, for two armies to operate against a combined army by lines, where from distance or want of concert they are independent of each other, is to confer on the enemy an advantage greater than that which has been demonstrated to follow from interposing between the parts of an extended front, and that advantage will be such as to compensate for considerable inferiority of numbers. This is illustrated by the campaign in Germany in 1796, where the Archduke Charles was opposed to the two armies of Moreau and Jourdain; and by Napoleon, in a splendid manner, in his campaign of 1814. Again, the campaigns of Virginia, in 1861 and 1862, give examples of another form of the same operations, the grand principle in all these cases being that one concentrated army uses a retarding and inferior force on one side and brings a preponderating force into action on the other side. The operations of Jackson in Virginia, moving with wonderful rapidity from one side to another, will be fresh in the memories of our readers.

One instance of this concentration of an army against a portion of the enemy's forces, which we cannot pass by without comment, is the campaign of Waterloo. In this case, the English and Prussian bases were divergent, the English being based on Antwerp and Ostend, the Prussians on Cologne. Division was thus to them even more dangerous than in any of the previously named cases. Napoleon, breaking in upon their front, intended to separate them in such a way as to open the road to Brussels. He hoped to defeat Blucher's

corps in succession, before they could assemble, and, driving him back towards the Rhine, to hold him in check with a containing force, and throw his whole force upon Wellington. But he was held so long in check by Zieten, that Blucher's corps had united at Ligny before he could attack. Still they were defeated, and they retired during the night of June 16; and on the 17th Napoleon detached Grouchy's force in pursuit. Then, quitting the field of Ligny; with the remainder of his army, he joined Ney, who had fought the battle of Quatre Bras on the 16th, and threw the whole weight of their combined forces on Wellington at Waterloo. But Blucher, after Ligny, instead of retreating along his communications to his base, had taken the gallant and hazardous step of marching to join Wellington by a circuitous route, though Grouchy was descending directly on his communications. Grouchy's pursuit was wrongly directed, and he failed to intercept Blucher, whose troops arriving on the field of Waterloo, on the French flank and rear, while the English advanced in front, decided the action against Napoleon.

In this campaign, as in others, Napoleon adopted the plan which should always be followed where it is thus intended to break in on an enemy's front, and divide his forces. He divided his army into two wings with which to feel the enemy on either side, and a central reserve to reinforce either at discretion. Thus first he joined his centre to his right at Ligny; then leaving his right wing to pursue the Prussians, he joined his centre to his left for the attack upon Wellington. But he had scarcely sufficient force to count on success, even if Blucher had not succeeded in again combining with Wellington.

There is one other operation which we have not noticed, the case of dislodging an army by operating with a detachment against its rear, as Sherman repeatedly dislodged Johnston in Georgia, in 1864. This movement, involving separation of the attacking force, is dangerous, and justifiable only when the front of a position is unassailable, and a movement against the enemy's flank with the entire army unsafe; or when the roads will not permit the entire army to advance in effective order, or when the separating army possesses divergent lines of retreat; but, in every case, *an army thus separating must be greatly superior in numbers*, or it exposes itself to almost certain defeat.

Both methods of strategical enterprise—against the enemy's communications and against his front—have now been touched upon. For an army strong enough to fight its enemy's whole force, action against his communications is, wherever safe and practicable, most desirable; and the enemy, when formed to a flank to resist such an attack, may perhaps be separated and destroyed piecemeal. Such a success would be the perfection of strategy. But if an army be weak, it should endeavour to break in and divide its enemy's front; for by a blow at his communications it would force him to concentrate, and so compel what it ought to prevent. Generally, to break the front will be found the most decisive and readiest method.

We have thus far discussed strategy only with reference to its general principles, and on the assumption that the theatre of war opposes no difficulties of a special nature. But a glance at a map will show that the theatre of war is generally a varied and irregular surface, crossed by rivers and mountain chains, and in some places studded with fortresses. To appreciate thoroughly the influence of these is one of the most important matters for the student. The character of a country, its cultivation, the direction of its chief rivers and mountain ranges, the lines of roads, the relations between the armies and the obstacles in the theatre of war, require close study in order that a plan may be resolved on, that the nature of the marches and encounters may be foreseen and provided for, and that the proportion of arms may be properly adjusted, as well as the nature of the supplies and equipment most necessary for the campaign.

The configuration of bases and frontiers will affect a campaign from its outset. We have already shown the advantage gained by Moreau in 1800, by the possession of the angular base formed by Switzerland and the Rhine frontier; and how the holder of this base is enabled to fall on the communications of a German army near the source of the Danube. Again, the local character of the Peninsula was most important. Wellington held an almost impregnable base in Portugal, which could be approached only by two lines, defended by Ciudad Rodrigo and Badajoz respectively. On the other hand, the French communications from Bayonne were always exposed to a flank attack by the English as possessing command of the sea; and the French were confined to that and one other bad line by the chain of the Pyrenees, through which these were the only outlets. Thus, too, in the campaign of 1866, the salient angle of the Bohemian mountain frontier afforded the Austrian army, if they had been prepared, an opportunity of issuing and penetrating the Prussian front, which was necessarily separated in Saxony and Silesia; while, on the other hand, it gave the Prussians a chance of striking at the Austrian communications, and forcing them out of the angle. Generally, with such a base, the advantage is with the side assuming the initiative, and greatest with the side holding the salient angle.

Obstacles (by which we mean obstacles possessing advantages for defence, and which cannot be passed by deployed troops) present peculiar strategical problems. A long line of mountains that meets an advancing army in front is not, unless especially steep, a very serious obstacle; nor should it be defended pertinaciously, especially at a number of points, for usually it can be turned, or penetrated by a variety of passes or paths. Its uses to the defender will be to retard the enemy's advance,

and to limit him to a few difficult lines of supply when he has passed it. The best plan to defend it is merely to hold the passes with detachments, posting the army where it can force the enemy issuing forth to form front to a flank.

A river, on the other hand, allows the defenders to deploy and bring powerful converging fire on the column attempting to cross; but there are so many passages across a long river, and it is so easily bridged over, that the difficulty of guarding it becomes very great.

The conditions already arrived at as regards breaking the front or turning the flank, apply equally to the passage of a defended river. In case of its flank being turned, it is better that an army defending a river should, if possible, cross and strike at the enemy's communications in return; but such a course is seldom adopted, and if he remain on his own bank, the defender's most effective action will be against the outward flank of the turning force. The passage of a river at points deliberately defended is, however, difficult, and costly to the assailant. Thus, at La Rothière, in 1814, the Austrians could not pass the bridge throughout the whole battle; and at Fredericksburg, in 1862, Lee routed the Federals upon crossing the Rapahannock. Passages are generally made by stratagem, examples of which may be found in Moreau's passages of the Rhine in the enemy's front in 1796 and 1797; while for examples of passing a river on the flank of the defensive army, we may select Wellington's passage of the Gave de Pau in 1814, and the French passage of the Ticino in 1859.

The true use of obstacles which cross the assailant's path is to give their possessor increased power of manœuvring offensively, and of taking the enemy at a disadvantage; but they have defensive uses also, viz. to cover a flank movement; to afford opportunity for rallying a beaten army, as the Mincio did after Solferino; to enable part of an army to hold a forward line and protect territory till reinforcements arrive; to cover a concentration in rear, as Zieten did on the Sambre; or, lastly, to cover a retreat, a use to which they were most skilfully applied by Massena retreating before Wellington in 1811. But to attempt to hold them entirely on the defensive will only be to give aid to the enemy, to whom they will afford opportunities of displaying strategical skill. An advancing army, wresting a river from its defenders, will make use of it as a sort of advanced base, and thus secure its line of communications.

While direct obstacles are at once seen to interpose difficulties and delay in the way of an advancing army, there is another class of obstacles, the effect of which is not so obvious, viz. those of which the general direction is parallel to the path of the advancing army. Such an obstacle was the ridge of the Monte Junto in Portugal, at right angles to the line of Torres Vedras, which compelled both Massena and Wellington to operate by one side of it only, under peril of suffering the penalties to which a divided army is always liable. A chain of mountains running in such a direction may also be used as a screen for a movement against the enemy's communications, as in the Leipsic campaign. When a river forms an obstacle of this nature, it often exercises great influence on a campaign. An advancing general cannot venture to leave behind on his flank a defended passage of a river of this kind, unless he leaves a covering force equal to that of the enemy; otherwise he is in danger of his flank and rear being attacked. It is evident, then, that the advancing army must possess greatly superior numbers. Its risk is, however, lessened if the defenders are in possession only of one bank; and hence it is, as the Archduke Charles points out, that the first care of a general posted on the Danube should be to establish a double bridge-head, i. e. a work on each bank, securing the passage of the army.

In fact, an obstacle of this kind confers on its possessor all the advantages of the angular base augmented, because extending to both sides of the theatre. It presents a succession of points which must be either attacked at a disadvantage, or turned under protection of a covering force, and either course requires superior numbers. The army that advances offers an advantage to its adversary, who, to profit by the position, must take post near a point of passage, and await the movements of the advancing force.

Great additional complexity is introduced into the question of the influence of rivers of this class, when two or more flow in the same general direction and converge. If the operations lie altogether on the outward bank of one of two such rivers, the other loses all its immediate importance. But it may happen that the most direct routes lie between such rivers, and, in the windings of the streams, pass from one bank to the other. An army advancing by these routes must sometimes have to force a passage at a known point, and, while moving on the inner bank of one river, it will be exposed in flank to the direct attack of an enemy who makes the other river the pivot of his stroke.

There remains one class of obstacles of great importance. When armies were slow and cumbrous bodies, fortresses gave great strength to frontiers, exposing the convoys of troops, as they moved along the main roads, to sallies from the fortresses placed on these roads. But they were costly defences, swallowing up huge bodies of troops; and when armies became more mobile, fortresses were generally *masked* by a detached force left in front of them: nor do they now prevent armies from marching past them. Thus, in the German campaign of 1866, the Prussians masked no less than five fortresses, Königstein, Theriesenstadt, Josephstadt, Königratz, and Olmütz.

But fortresses have great uses if properly situated, and if impregnable to open assault; for

they can be used as temporary bases round which an army may safely manœuvre. Situated on rivers at points where the main communications cross, they are most valuable. If situated astride of direct obstacles, they give security to the front or flank of a defending army, enabling it to force the assailing army to fight with a front parallel to its communications. Placed astride of rivers, parallel to the advance of an enemy, they form a pivot for a flank attack, or defend a passage, as may be required.

As to their position on frontiers, an open frontier is best guarded by a few great fortresses, situated on the most direct lines to the capital. If the issues of a frontier are few, the fortresses guarding them become of immense importance. For this reason Wellington made such repeated attacks upon Badajoz and Ciudad Rodrigo, as commanding the only two avenues between Spain and Portugal.

It is difficult to overrate the importance of fortifying a capital. Had Paris been fortified, the campaign of the Allies in 1814 might have had a very different termination.

We have thus sketched the main features and principles of strategy, the grand elements of which remain unaltered by the increased civilisation of the age. But the advance of civilisation, increased wealth, more rapid and certain communication, will enlarge the sphere of strategy, and will make greater demands on the intellect of the commander. Steam, telegraphs, railroads, and commerce increase the advantage which superiority of conception always claimed; just as the growth of Europe in agricultural wealth and the improvement of her highways enabled Napoleon and his contemporaries to use a strategy which to Frederick and Marlborough seemed too bold, or was applied by them only in countries perfectly friendly, open, and well tilled beyond the custom of their time. Nor let us doubt that mankind will be great gainers by the change. Whatever increases the rapidity with which the great machines called armies are worked, and causes the fate of a war to be sooner declared, will diminish the suffering caused by the struggle to the populations. The more perfect the system of supply and conveyance, the more striking the strategy, by so much the less will it be worth the while of generals to prolong their operations for the purpose of subsistence, and of governments to hold out for unreasonable terms in the hope of wearying out the foe. The tendency of strategy being evidently then, in this direction, and its theory unchanging, while in practice it becomes bolder with increased means, it remains to trace the developement of the tactical part of warfare under the most modern conditions, i. e. to see what improvements have been made during the past sixty years in the use of the various arms in face of the enemy. (*Edin. Rev.* Jan. 1866.)

If the operations in a theatre of war have undergone great and remarkable changes since the feudal times, no less radical and complete have been the alterations in the method of conducting the movements of armies on the field of battle.

When soldiers were armed with pikes, axes, and shields, the best formation was that of deep columns, which possessed momentum, and were able to withstand the charges of men-at-arms. But on the introduction of firearms (as only two ranks can discharge their pieces), a line was generally formed three deep, the third line loading for the others. Deployment into long lines was a matter requiring precision of drill, and in the time of Eugene and Marlborough was but slowly effected. Positions were chosen deliberately, and two armies drew up and attacked in parallel order. Manœuvring, as we call it, was almost unknown. Marlborough's great skill lay in detecting the weak parts of the opposing line, and attacking them with heavy blows. It was thus that at Blenheim and at Ramillies he pierced the enemy's line. The armies of Frederick, better drilled, as we have already shown, were able to manœuvre to a flank, and thus he contrived to outflank his enemy, and place his line within striking distance obliquely across the extremity of his adversary's line. His army was not an aggregate of corps, divisions, or brigades, each capable of acting independently; it was itself the unit. It camped and fought in two lines; it moved to a flank in two columns, ready at a moment's notice to wheel into line, and to the front in four columns ready to deploy. At Prague it was by this flank movement that he defeated the Austrians, turning their right, and then piercing the centre. The army whose flank is thus turned, will naturally (as on this occasion the Austrians did) try to throw back the turned flank; and thus it is formed in a salient angle. This is a dangerous formation, as the whole force of the assailant may be brought to bear on one flank; the advance of either flank causes a gap at the angle; the face assailed will be liable to be turned on both flanks; the fire of the assailant's artillery enfilades one or both faces; and the defeat of the assailed wing compromises the retreat of the other.

Seeing, then, the advantages of turning a flank, the French at Rossbach in 1757 tried to take the same advantage of Frederick, but failing utterly, they displayed the fact that an army attempting openly to outflank another, but not succeeding in turning the flank, and finding its enemy drawn up across its path, is itself outflanked; so that, under ordinary circumstances, such an enterprise will be futile and disastrous, for the army against which the movement is directed has a less distance to move.

The Prussian system of manœuvres was now adopted throughout Europe; and, as we have already briefly mentioned, remained in force till Napoleon's distribution of an army into corps, each complete in its own staff, hospital, and commissariat, each able to be treated as a separate army for movement and supply, each able to be separately handled on

the field of battle, introduced not only great changes into strategy, but into tactics. 'An organisation by corps-columns moving independently, with connecting detachments between them, changed where convenient into lines, and covered with skirmishers to shake the enemy's order and keep him out of range. Cavalry less exposed than of old, yet partly used to connect the movements of the infantry divisions and guard their flanks—reserves increased to a large proportion of the whole force, and strengthened by a powerful artillery—the latter arm greatly augmented and placed more in mass—a careful occupation of natural obstacles in front by detachments, whilst the bulk of the divisions are sheltered where possible from the enemy's guns—such are the normal rules on which orders of battle were formed down to the time of the Third Napoleon.'

Let us now consider briefly the functions of the different arms, and the formations by which each attains its fullest influence. Modern infantry exercises its influence in battle either by firing on the enemy or charging. The first is a defensive mode of action; the second essentially offensive.

Cavalry attains its power by the impetus of its charge, and a certain distance must interpose between its front and that of the enemy to be assailed, in order to give to its advance both perfect order and great momentum.

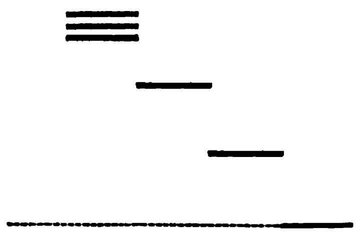
Artillery possesses the power of firing at longer range, and with more destructive projectiles, than infantry. It should begin to fire beyond the effective range of small arms, but not so far as to be practically out of range; and it should fire diagonally or transversely against lines of troops. Against columns it may fire either in front, in flank, or transversely.

In studying the formation of infantry, it is evident that long deployed lines will give the greatest effective fire; but in the advance columns will be more steady, and less liable to be broken, while they are also more able to obtain shelter. On arriving near the enemy, they can either deploy and engage in musketry fire, or charge with their whole force.

In Frederick's time the well-drilled Prussians generally attacked in line; but the republican and imperial armies of France were trained to attack in column, the front being covered by clouds of skirmishers. The most usual formation was line of columns of battalions; sometimes a mixture of line and column. And as it is probable that columns would never charge a line which stands firm, but deploy and try the effect of their fire, small columns easily deployed will be most effective. When the action has gone on for some time, when the fire of artillery has had its effect, and the defensive line is no longer intact, the attacking force, feeding its line from its supporting columns, will endeavour to quench the enemy's fire, and finally launch its columns to the assault.

Thus, then, as we have shown the open turning of an enemy's flank to be a perilous move, the great object of modern battles is to bring a superior force to bear at a certain point of the battle-field. The design is screened by false attacks, by features of the ground, by the advance of skirmishers. And as the attacking force must be strengthened at the expense of some other part of the line, that weakened part must be kept out of the engagement. *Echelon*, or *stair* formation, is very favourable to this, allowing the weakened or exposed flank to be retired out of

Fig. 2.



the way, while line may be formed on any front, or a new front of échelons may be formed by a simultaneous wheel. The head of the formation may be reinforced for attack; if successful, the remaining échelons come up and form line on it—if opposed strongly, they successively reinforce it—if defeated, they cover its retreat. Sometimes oblique échelon is em-

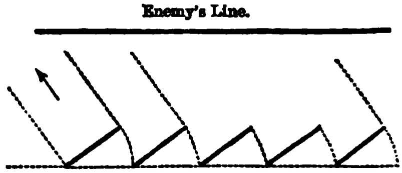
Enemy's Line.



Original Line.

ployed to gain ground to a flank in advancing. If columns are successful in the attack, and pierce the opposing line, they deploy right and left, rolling up the enemy's exposed flanks, while through the gap cavalry and fresh bodies of infantry pour in to break the second line.

As regards the formation of cavalry, it should be stationed far enough behind the object to be defended to allow it to obtain the proper momentum during its advance; and as it has to seize special fleeting moments for its attack, it should be kept formed in order of attack. It must never fight in close column; but a series of lines may with advantage charge on a square or column, the succeeding lines attacking in turn, as the preceding lines, failing to penetrate, wheel outwards.

Cavalry combined with infantry may attack in flank the enemy's column, already engaged in front by the infantry; the attacked troops must in such cases form squares, thus giving the line of infantry attacking them a great superiority of fire. Cavalry charges, unless supported by infantry, are indecisive, for the

infantry are required to keep what the cavalry have gained.

Artillery must, of course, be formed in line, though that line need not be perpendicular to the enemy's front. Its fire is most effective when down a gentle slope, or along a plain over which the guns have a certain command. Combined with cavalry, horse artillery advances rapidly, opens fire, and ceases only when its front is masked by the advance of the horse; and in retreating, it similarly halts, fires, and then gallops on to overtake the retiring cavalry. In these cases, it ought always to be on the flanks of the cavalry, so as to be out of its way. Cavalry, without artillery, is powerless for defence; with good artillery it may be valuable for attack, and itself protected. Artillery should not be placed in rear of other troops, for the rush of shot over their heads would make them unsteady. Nor should infantry be placed in rear of artillery, but on or in rear of the flanks to protect the weak points; the guns can protect their own front. Artillery, when on the defensive, will fire at the attacking columns; when on the offensive, partly at the enemy's artillery, to prevent its destroying the advancing columns.

Such, then, being the functions of the three arms and their relations one to the other, we may now consider the formation of the line of battle, and the occupation of the ground. The line of battle shouid be a disposition on a great scale, of the three arms, for their effective individual action and mutual support.

And, first, it is necessary to gain a clear idea of the proportions of troops to space. Foot soldiers standing in the ranks occupy each 21 inches of lateral space; thus 12 men occupy 7 yards. Cavalry occupy each man and horse 1 yard laterally. Guns 19 yards from muzzle to muzzle, with 9½ yards on each flank. Apply this to larger bodies of troops, and we get 6,000 infantry in simple line two deep occupying about a mile: a regiment of 6 squadrons of cavalry, with intervals between squadrons, about 350 yards; a battery of six guns, 114 yards.

Allowing space for officers, intervals, and two batteries of guns, a division of 12,000 infantry with 12 guns, in two lines, each two deep, will occupy, with battalions in front as skirmishers, about a mile in length. As this distance is too long to be defended by guns from one flank only, its guns should be disposed on both flanks. The cavalry also should be on the flanks of the whole line, for if it were placed between the divisions in column, it could not deploy without masking much infantry fire, and if in line, all that space which it occupies would have no fire to oppose to the enemy. Hence it is generally placed in rear of the flanks of the line of battle, though a small number of squadrons may be advantageously placed in rear of the first line, so as to act between the divisions if occasion should arise.

The second line should be near enough to the first to afford support, but not so near as to give the enemy's artillery a double chance. A distance of from 200 to 300 yards is generally considered best. The most convenient formation for this line will be battalions in double or single column of companies.

As regards the choice of a position on which to form line of battle, it must be remembered that although a steep range of heights may be so strong as to defy superior numbers, the difficulty of making a counter attack from it will be proportioned to its inaccessibility. Cavalry and artillery will here be of little or no value. Such a position, then, may suit a general wishing to act purely on the defensive, and delay an enemy; it will not avail for measuring strength with him. The best ground for this will be such as obstructs the assailant but not the defender, e. g. the crest of a slight slope overlooking a plain along which the enemy must advance. A river in front, if the passages are in the defender's hands, may be useful, provided the assailant's bank do not afford him concealment for a turning movement.

An impassable obstacle extending partly along the front may shelter guns, but will render other troops posted behind it useless in an action, and so is bad. Again, to occupy a position intersected by an impassable obstacle, is only to offer two halves of the army in succession to the enemy's whole force. But if the assailant can be compelled to advance on each side of such an obstacle, it is a great advantage to the defender. Again, the ground in front must not afford shelter to the advancing troops of the enemy, or even to his skirmishers.

Defensible points, such as hamlets, farms, churches, &c., within easy distance of support, will increase the defender's strength; but unless they are within cannon-range of the line, and easy of access from it, it is better to destroy than hold them. Such points in the actual line of battle are very disadvantageous, for they break the line, and if once gained by the enemy, give him a footing in a dangerous position. In arranging a line of battle, it is desirable to protect the flanks, not by insuperable obstacles, which hamper the defender, but by such defensible posts as we have named.

The student of tactics cannot do better than study the disposition of the troops at Solferino, at Austerlitz, and at Waterloo, of all which battles full accounts have been handed down. Our space forbids our entering upon them here. Colonel Hamley draws from them the following deductions:—

'That in ordinary circumstances the formation in two continuous lines prevails, the exceptions being: (1) refused portions of the line, where the formation may neither be continuous nor on two lines throughout; and (2) portions of the line reinforced for a special purpose, generally for attack.

'That columns are the only formation for the advance and the attack, with the single exception of troops in line, which, having awaited the attack and compelled the hostile columns to

pause, charge, in their existing formation, over the short interval that separates the bodies.

'That of the various kinds of columns for attack, battalion-columns have been most resorted to and most successful.

'That general attacks of either cavalry or infantry should be supported by the other arm, and preceded by a concentrated fire of artillery.

'That cavalry is not uniformly stationed on the flanks of the line of battle, especially when a flank is otherwise supported (as at Austerlitz); but that it should uniformly cover the flank of an attacking force which, by advancing, is separated from the rest of the line; and that, when the attack assumes the salient form, a force of cavalry should be stationed near the angle, so as to fill the gap and operate on the flanks when the faces open outwards; and that, for these purposes, the place for great reserves of cavalry is near the centre.

'That artillery does not always occupy spaces in the general line—the exception being when the downward slope allows it to be posted in front of the infantry without giving double effect to the enemy's projectiles.

'That the proper use of reserves is not to keep them in hand till the last moment, but to consider them as a *disposable force*, ready to support any point, or aid the enterprises of any part of the line, at any period of the battle. Nevertheless, it is well always to keep a part of them fresh to the last; thus, at the close of the battle of Austerlitz, Napoleon had still untouched battalions ready for any effort; and the two battalions of the Guard which did not join in the last attack at Waterloo alone withstood the general wreck, and in any degree covered the retreat.

'The worst use, however, that can be made of reserves, is to fritter them away by repairing gaps and losses throughout the line: they should act as much as possible in masses.

'That, when divisions act together, they do not form the one the second line to the other; but that each division forms its own first and second line with its own brigades, while the brigades form partly in each line by regiments. The reason of this is, first, that the jealousies of rival commanders of divisions might lead one sometimes to withhold support from another; secondly, that a general's task is much simplified, and he has much better hold of his troops, if his command extends *in depth* rather than *in breadth*.'

Two kinds of tactical advantage have been here discussed: the occupation of favourable ground such as will obstruct the enemy only; and the combination and arrangement of the different arms so as to gain the best effect. But it was also pointed out that the turning a flank or breaking a line may lead to victory by producing new relations between the hostile lines. To obtain such a victory, however, the first successful attacks must be followed up at once. The advanced portion of the assailant's army must be strengthened, the remainder withdrawn out of reach. Dispositions for this must be made beforehand, and hence arise *orders of battle*, or certain relations existing between the hostile lines before or during the encounter. The end and aim of the order of battle is to produce such relations between the hostile lines as ultimately to bring a sufficient part of one *in battle array* across the extremity of part of the other.

An army may attack its enemy in front or flank. If on a flank, say the right, it must retire its own right flank, and so it will be in *oblique order* at the moment of attack; and the examples of the Prussians' defeat at Kolin, and that of Soult at Pampeluna, show the necessity of keeping the retired wing out of the way for a certain time, and prove that it is dangerous to turn an adversary with one wing, unless you refuse or protect the other. But the refused wing must not be kept altogether out of action. It must be engaged either when the progressive advance of the line brings it into contact with the enemy, or if the enemy changes front, by attacking the flank of his new line.

Modern armies no longer, like Frederick's army, adhere absolutely to the oblique form, but adopt its spirit, reinforcing the head of the attack from the reserves, or second line of the refused wing, and masking the front with skirmishers and artillery, under cover of which the troops of the attacking wing are brought into the best position. Battalion columns in échelon, well reinforced at the head, protected on the outward flank by cavalry, with the batteries assembled on the inner, would be a suitable formation for a flank attack. Above all things, the *continuity* of the whole line must be preserved during the attack.

But the commander of an army against which such a movement is directed may strike in return at the attacking wing, in which case, if successful, he will drive back the enemy along the line by which he advanced; or he may deal his counter-stroke at the refused wing, as Napoleon did at Austerlitz, in which case success will be far more decisive, for having beaten the refused wing, he may turn, and envelope and destroy the other. This will be the best course, unless distance or position should render it impossible.

The attack of a wing, or of a centre and wing, or the order écheloned on a wing, are all varieties of the oblique order.

The danger of the formation in a *salient angle* for defence has been already shown; but there are cases where (as at Gettysburg, where the Federal forces, so drawn up, had at the angle a hill protecting the lines from enfilade) the formation may be safe. But attacks almost of necessity assume this order, for on the centre of a line the continuity of the attacking force must be preserved. Such attacks, however, being unforeseen, are not met by a corresponding enclosing angle on the part of the defender, which is the only effectual counter-order. An attack of this kind, with cavalry at the apex, is

especially suitable when the enemy, by undue extension, has weakened part of his front.

Another *angular order* is the *re-entering* or *enclosing angle*, such as was formed by the Allies at Waterloo after the Prussian advance. But no enemy will wilfully enter into an enclosing angle; and if it were formed before his entry, it would but expose both flanks to his attack.

The *convex order* is merely another variety of the salient angle, and is a term loosely used to signify an army écheloned on the centre, or in some other angular form. Similarly, the *concave order* is but a form of the enclosing angle. Thus all *orders* may be reduced to *oblique* or *angular*.

In preparing for the attack, a commander's first object must be to disguise its nature from his enemy; and this he will do by concentrating his troops, covered by the fire of artillery, along the whole line. He must also bring masses of artillery to bear on the part which he means to attack, so as to weaken it before the advance of his troops; these will be preceded by swarms of skirmishers, who may also conceal the retirement of any part of his line.

In all cases, before deciding on the order of battle, the point of attack must be fixed upon. This the general must choose according to circumstances, selecting that point where his attack, if successful, will do the greatest injury, such as the flank resting on the base, the connecting point of two allied armies, the wing which is traversed by the line of retreat, or, of course, the weakest point of the enemy's line, bearing in mind that the mere forcing an enemy off the field without turning his flank, or breaking his centre, is an indecisive victory. Advanced posts must be captured: strong points in the line must be avoided, unless upon commanding ground, or where they can be cut off from the remainder. If one flank of the enemy is supported by an impassable obstacle, it will be well to drive the enemy back on that obstacle, so as to destroy him.

If an army be cut from its base, it is at least free from all necessity of choosing any particular lines, and may manœuvre freely to a flank. If a retreat becomes inevitable, it should be disguised by partial attacks, and carried out by the alternate retirement of troops. If an army quits a lost field with the intention of renewing the contest at the first opportunity, it should retreat in the most concentrated form possible; but if it is routed and seeks the shelter of its own frontier, the more roads it can move by the better. The pursuing force should try to strike, not the rear, but the flank of the flying army.

To sum up in Colonel Hamley's words: 'The assailant's order of battle must depend on the points selected for attack, and the selection of these points must depend on circumstances already discussed. A general, taking up a defensive line, or attacked while manœuvring, should seek to obtain as far as possible the following conditions:—

'1. By the direction of his front, to cover his line of retreat as squarely as possible, without lending a flank to the enemy.

'2. To occupy ground which cannot be approached within range unawares.

'3. To insure free communication between parts of his front.

'4. To conceal his movements and force as much as possible.

'5. To seize such advanced posts as will strengthen his front.

'Lastly, he must take up his ground with a view to the action of that arm in which he may be proportionately strongest or superior to the enemy.

'Viewing the case from the other side, the assailant must first choose his points of attack. In order to do this confidently, he must fully understand his adversary's dispositions, by reconnoitring, if possible, the whole extent of his line. . . .

'This done, the assailant must make his dispositions, (1) for disguising his attack, (2) for executing it, (3) for supporting it, and (4) for refusing the containing or defensive parts of his order of battle.'

The introduction of arms of precision has modified previously existing conditions, but does not seem to have produced any radical changes. The fire of infantry has extended its *effective* range from less than 200 to 600 or 700 yards, and has gained in volume and rapidity by the introduction of breech-loading arms. The effective fire of field artillery is extended from 1,200 or 1,400 yards to 2,000 or 2,500 yards. This would at first seem to imply that to advance against such a fire must be almost impracticable, but it is not so. Many reasons lessen the efficacy of these arms, most especially the conformation of ground, the smoke of artillery and musketry, the dust or fog, and the excitement and stress, moral and physical, of sustained conflict. All these greatly diminish the effect of weapons requiring a clear range and deliberate adjustment. Still the advantages of defence are doubtless increased by them to the army which in a sheltered position awaits the attack. The line of battle must be formed farther off, and the attacking troops must be longer exposed to fire.

An advance in line would, if it were possible, insure the least loss to the assailant, but such a thing is never practicable for a large force on average ground. Deep columns would be fatal, and must be absolutely condemned, so that apparently columns of small depth must be the formation for future attacks: but these must be covered by skirmishers in great numbers. Every possible shelter will have to be seized by the advancing troops; and their advance must be preceded by a concentrated fire of artillery. *Rapidity of movement must be made to counteract rapidity of the enemy's fire.* A lighter and quicker system of drill must be adopted, though the general principles in action will remain unaltered.

The same remark applies to artillery. Bat-

teries must all be made to move with rapidity, so as to be able to take action according to the enemy's rapid movements, and must be massed, as heretofore, for the decisive stroke in battle.

The value of cavalry under present conditions is more doubtful. Whether it will be able to hold its position as an agent in the shock of battle, is a question even as yet scarcely solved. It is argued that it will be destroyed by the projectiles of the enemy before it can reach the point of action. But here again increased rapidity, gained by increased lightness of equipments, must be acquired. Once closed with the adverse line, it has no more to fear than formerly. Its drill, too, must be simplified to admit of much faster manœuvring, and artillery must, as before, be associated with it in order to protect it. Whether it will ever avail against well-formed troops, must be decided by experience not even yet gained. That it will be as valuable as ever for covering a retreat, was clearly proved by the experience of the Austrian retreat after Königgratz; and 'launched in pursuit of a broken foe, it may finish a campaign which would else wade through fresh carnage to its woeful end.' But its highest application must depend on the genius of its commander.

As regards the influence of modern arms on manœuvres, it is probable that turning movements will be greatly employed to save the loss which must be suffered in direct attacks. But when an attack is judged practicable, the severity of the fire will probably always cause the two opposing parties to have recourse in a very short time to the use of the bayonet, and the army acting on the defensive will probably make great use of fieldworks.

The limits allowed in this article forbid our entering on the questions of the dispositions for the march that precedes a battle, and the many minor operations of war, such as advanced guards, outposts, convoys, reconnaissance, &c.; although these are of vital importance in the successful conduct of a campaign.

'In passing from the consideration of tactics, and the changes that art is undergoing, it seems necessary to refute but one more popular error, which has been countenanced by names lent to it with perhaps injudicious haste. It has been said that the rapid multiplying of railways and their dépôts must tend to modify the condition under which troops are brought into action. In so far as this relates to their actual collision, this is plainly an error. Cuttings, embankments, crossings, bridges, are none of them new creations. The defence of a railroad station is that merely of a building of certain size, and involves no new principles. Had the increasing wealth of civilised countries not spent itself in this way, it would have found, as it still finds, other outlets in forms of planting, building, draining, which would change particular fields of combat, but in no way affect a certain system already adapted for seizing or maintaining a given position, or show that it could be, as a whole, altered for the better. The idea, baseless when viewed in this light, has been supported by the alleged winning of the battle of Montebello by the French as a consequence of their actual use of a railway to bring up reinforcements; and the employment of trains during a single action has been mixed up with the general notion of the value of railroads for battle purposes. Space does not allow us to follow out the details of the affair where Forey won his reputation. It is enough to say that Rüstow (an able writer, and, as between Emperor and Kaiser, thoroughly impartial) denies in his work this pretended cause of the defeat of the Austrians, and ascribes it simply to the well-known want of resource and self-possession which has, for the last eighty years, constantly marked their general officers when detached. It may be added that the long annals of the American war give no reason to believe that we are near the day when commanders will arrange their order of battle with a view to bring their troops under fire by train.

'Far otherwise is it as regards the greater combinations of war. The wondrous facilities which steam conveyance and the electric telegraph afford for transporting and collecting troops and supplies seems to promise almost as great a revolution in strategy as gunpowder is admitted to have made in tactics. . . .

'The least observation of these phases of that gigantic contest (the American war), added to what we have lately seen in Italy and Denmark, is sufficient to show a great change to come in future European wars. Old lines of defence must vanish, bases formerly distant be brought near, concentration of great masses be the rule rather than the exception, months of preparation and of movement be contracted into days. As regards the strategy of purely inland campaigns, railroads and telegraphs, it may be freely assumed, will soon be so multiplied that their effect will be felt in this way wherever civilisation extends. This will be generally admitted. But it is not so apparent at first that a similar change may be expected wherever the theatre of war is open to approach by navigation. In spite of Crimean experience, and of the marvels worked by Grant when he had once felt his way to the true use of his steam transports, few are aware how immensely the naval powers of the world have augmented the striking force of their armies by the improvements in their fleets. France has been long the most formidable of neighbours; but it is not too much to say that her present policy of amity with England, and the undisputed rank of her navy as the second in Europe, has doubled at the very least her warlike means against all the other Continental powers.' (*Edin. Rev.* Jan. 1866, 'Recent Changes in the Art of War.')

In this brief sketch of the operations of modern warfare, we have followed closely the order of subjects, and the manner of treatment, adopted in Colonel Hamley's invaluable work, *The Operations of War explained and illus-*

trated (London and Edinburgh 1866), which, as it is the latest, is also the best work in the English language for the student of the art of war. The reader who wishes to pursue the subject further, may find study for a lifetime in the works of Clausewitz, the Archduke Charles, Jomini, Marmont, Baron Ambert, and Napier, the *Napoleon Correspondence*, the *Wellington Despatches*, and other works, to which these will lead him. We would conclude with another sentence of Colonel Hamley's: 'The moral is, not that numbers and wealth must prevail, nor that great generals are heaven-born: it is, on the contrary, that the conditions of success are attainable and capable of demonstration; that the preparation of study and thought is essential to skill in war; and that, being thus prepared, a leader, in order to achieve the most notable successes, need not be gifted with inspiration, but only with the more appreciable, though still rare, combination of sound sense, clear insight, and resolution.'

War, Private. According to the ancient Greek theory, as well as to those of barbarous nations generally, men are in a state of natural enmity, and friendship is distinctly a matter of special contract. Hence, apart from this contract, there is on this hypothesis a right inherent in every man to avenge his wrongs against his neighbour if he is able to do so. If the city or state to which he belongs can do this for him, so much the better; if not, he reverts to his own inalienable privilege. To this plea the feudal nobility of the middle ages had recourse without scruple, when legal compositions, as of WERBGILD, proved insufficient, or other causes of quarrel occurred. Against these feuds (faida) or private wars, many of the capitularies of Charlemagne are directed; but, after his time, the practice continued almost without let or hindrance. In the absence of judicial tribunals able to enforce their awards, Mr. Hallam thinks that the higher nobility of France in that age may be regarded as in a state of nature with respect to each other, and entitled to avail themselves of all legitimate grounds of hostility. (*Middle Ages*, ch. ii. part ii. § 2.)

Ward. In Feudal Law, the heir of the king's tenant in capite during his nonage was so called; and, in general language, all infants under the power of guardians. [GUARDIAN.] The court of *wards and liveries*, for cognisance of various matters relating to the king's prerogative, was established by Henry VIII., and abolished at the Restoration. (*Archæologia*, vol. ii.)

Ward's Paste. A quack medicine, of which *pepper* is the active ingredient, and which has obtained some celebrity as a remedy for piles, and for fistulæ and abscesses about the rectum.

Ward-room. In large ships of war, the cabin set apart for the abode of officers ranking as lieutenants. Small ships have no ward-room.

Warden, Lord, of the Cinque Ports. [CINQUE PORTS.] The constable of Dover Castle was created warden of the Cinque Ports and guardian of the adjacent coast, by William the Conqueror: an office resembling that of the comes littoris Saxonici in the decline of the Roman empire. The lord warden had a peculiar maritime jurisdiction. His jurisdiction in civil suits has been recently abolished (18 & 19 Vict. c. 48). The office is now little more than a sinecure, and valuable chiefly as giving a right to the use of Walmer Castle as a residence.

There is also a lord warden of the STANNARIES.

Wardmote. A court in each ward of the city of London, which has power to present defaults in matters relating to the watch, police, &c.

Warehouse, Bonded. A building in which duty-paying and excisable articles can be stored during the period which intervenes between their importation or production and their consumption. The charge paid for storing such articles is as low as possible; and, as a rule, if they are re-exported, or if, being produced at home, they are consigned to foreign countries, no duty at all is paid. The object of such an arrangement is that the tax levied indirectly on consumption may be as light as possible, because the period between the payment of the tax and the consumption of the commodity is as short as possible.

The manifest advantages which the general public obtain by the adoption of a warehousing system, was early recognised when the pressure of public debt and increased domestic expenditure aroused the attention of financiers. Hence Sir Robert Walpole attempted, in 1733, to establish such warehouses in the principal British ports. But the leading London merchants, to their infinite disgrace, stirred up the public, by a variety of ridiculous fallacies, to resist the system; and the odium excited was so great, that Walpole was obliged to abandon his project. The weak point in Walpole's scheme was the double arrangement of levying excise and customs duties on imports. If by means of a bonded warehouse the duty could be levied as nearly as possible at the time of consumption, there could be no reason for retaining an excise on such articles. The opposition to the arrangement, however, was so strong, that for seventy years this obvious and useful system was postponed. Now, however, it is applied to every kind of article produced abroad or at home, on which any duty is charged, with one exception, corn, the duty on which, 1*s*. the quarter, or 3*d*. the cwt., is a landing not a bonding duty.

The advantages of the warehousing system are greatly increased by the facilities of transport which are accorded by railways: at present, the trader in duty-paying articles keeps the least possible stock in his possession; for, in consequence of the ease with which he can obtain a fresh supply, he economises that portion of his capital which is invested in the payment of duties as fully as he can.

Waring's Method. The object of this method is to separate the roots of an algebraic equation; it requires the formation of the equation whose roots are the squared differences of the roots of the original. [EQUATION OF SQUARED DIFFERENCES.] If k^2 denote an inferior limit of the roots of the latter, a and b being respectively the superior and inferior limits of the roots of the original equation $F(x)=0$ (all which limits can be easily determined); then, from the signs of $F(a)$, $F(a-k)$, $F(a-2k)$. . . $F(b)$, the positions of all the real roots of the given equation may be at once ascertained; for, between any two adjacent values $a-mk$ and $a-(m+1)k$, not more than one root can be situated, and its absence or presence will be indicated by the like, or opposite, characters of the signs of $F(a-mk)$ and $F(a-\overline{m+1}k)$.

Waring, who was Lucasian Professor of Mathematics at Cambridge about the year 1760, published several papers on equations in the *Phil. Trans.*, as well as a separate treatise entitled *Meditationes Algebraicæ*, at Cambridge, in 1770.

Warming and Ventilation. [VENTILATION.]

Warmth (a Teutonic word, akin to Sansc. gharma, Gr. θερμός). In Painting, a tone of colour arising from the use of colours expressive of heat, or the so-called hotter colours, as reds, deep yellows, russet browns, &c.

Warp. In Naval Affairs, *warp* signifies a rope laid out for the purpose of moving the ship. *To warp* is to move a ship from one position to another by means of warps.

WARP. In Weaving, the *longitudinal* threads of a woven fabric; they are crossed by the *transverse* threads, or *woof*.

Warping (Fr. guerpier). A mode of increasing the fertility of tillage lands on the banks of rivers liable to be overflowed by them. It appears to have been first practised in Britain on the banks of the Trent, Ouse, and other rivers which empty themselves into the estuary of the Humber. The waters of these rivers, from passing through a great extent of alluvial country, are, after heavy rains, exceedingly muddy; and they are in that state conducted over the adjoining surface in portions enclosed by banks, and there suffered to deposit their mud, which is technically called *warp*, and which being of the depth of an inch or two, adds greatly to the fertility of the soil, and indirectly on consumption may be as light as existed on the banks of the Po, and other rivers in the north of Italy, from time immemorial.

WARPING. In Architecture. [CASTING.]

Warrant (Welsh gwarant). In Law, a precept under hand and seal, directed to a proper officer, to arrest an offender.

Warrant of Attorney. In Law, a power given by a client to his attorney to appear and plead for him, or to suffer judgment to pass against him by confession. It authorises a creditor to enter up judgment and levy execution, and is frequently granted as a security for a debt.

Warrant Officers. In the Navy, the gunner, boatswain, and carpenter.

Warranty. In Law, as applied to lands, a promise or covenant real annexed to lands or hereditaments, whereby the conveying party was bound to warrant the title of the same, against all men. But the ancient law of warranty of real property, after having been long obsolete in practice, was superseded by the stat. 3 & 4 Wm. IV. cc. 27, 74. It is, however, still the practice to insert in conveyances *covenants for the title* to the land conveyed, which to some extent answer the purpose of the old warranties.

With regard to warranty of things personal, it is the general rule that a purchaser of goods and chattels may have a satisfaction from the seller, if he sells them as his own and the title proves deficient, without any express warranty for that purpose; but that with regard to the goodness of the things so purchased, the vendor is not bound to answer, unless he has expressly warranted them to be good, or unless he has in any way misrepresented them; but a warranty is implied in certain cases by the custom of trade or the nature of the contract. [TITLE.]

Warren (Fr. garenne, from the Teutonic wahren, *to protect or defend*). In Law, a franchise or place privileged for the taking or keeping of beasts and fowls of warren, which are said by some to be only hares and rabbits, partridges and pheasants; others add quails, woodcocks, waterfowl, &c. The franchise is from the crown by grant, or prescription which implies grant. It is often called *free warren*, and in some cases denotes the right of sporting over the land of another; for by the common law the right of taking or destroying game belonged exclusively to the king or to those to whom he had granted it, and it not unfrequently happens that under ancient grants the right of warren, i. e. of taking and destroying game, has become vested in persons not the owners of the soil. [GAME LAWS.]

Warwickite. Native borotitanate of magnesia and iron, met with in dark-brown to black crystals, in granular limestone, near Edenville, New York, U.S.

Washboard. In Sea language, a movable piece of board placed above the gunwale of a boat, or elsewhere, to prevent the water from washing over.

Washer. A circular piece of leather, or pasteboard, placed at the base of a screw, so as to prevent the metal surfaces from being injured when it is screwed home; it is also used to render screw and other junctions air-tight.

Washingtonite. A kind of titaniferous iron-ore of a steel-grey colour, met with in Connecticut, and said to occur, also, at Breaghy Head, in Donegal, and at Ballinascreen, co. Derry. Named after General Washington, president of the United States.

Wasp. [VESPIDÆ.]

Wassail (A.-Sax. waes hael, *be in health*). A common salutation used in drinking: whence the *wassel-bowl*, which was anciently carried

round on New Year's Eve. 'A carol for a wassel bowl' will be found in Ritson's *Ancient Songs*, 1790, p. 304. (Brand, *Popular Antiquities*, vol. i. p. 1.)

Waste (Lat. vastus). In Law, the destruction or material alteration of things forming an essential part of the inheritance; as houses, timber, &c. Neglect of repairs is termed *permissive* waste; active injury, *voluntary* waste. The Court of Chancery will interfere by injunction to restrain the committing of waste by persons having estates for life or other limited interests in land; and even although the estate or interest of the person attempting to commit waste be expressly given to him *without impeachment of waste*—in which case he may cut timber in a husbandlike manner for his own benefit, work mines, and the like—the court will still restrain him from felling ornamental timber, pulling down the family mansion, and similar acts, which are known as *equitable* waste; and a person improperly committing waste or equitable waste may be made to account for any money produced thereby at the instance of those entitled in remainder.

Waste Land. Any tract of surface not in a state of cultivation, and producing little or no useful herbage, or wood. It was estimated by Sir John Sinclair, about the end of the last century, that the quantity of waste land in Great Britain amounted to 22,107,001 acres (England and Wales 7,888,777, Scotland 14,218,224), 3,000,000 of which he considered capable of being brought under the plough, and the greater part of the remainder of growing wood. Large quantities of this common and waste land have been enclosed during the present century, and the amount of waste land in England has been so much reduced, that some alarm has been lately felt, lest the progress of enclosures should deprive the inhabitants of large towns of their accustomed opportunities of exercise and recreation. Steps have been taken in many cases to preserve for public use commons situated in populous districts, and an Act of Parliament was passed in 1866 to make provision for the improvement, protection, and management of commons near the metropolis.

Watch (A.-Sax. wacian, Ger. wachen, *to wake*). This word is frequently used to denote the portions into which the night was divided for the duties of sentinels. Thus the Romans had four watches, and the Jews three.

WATCH. A well-known portable machine, moved by a spring, for measuring time. When executed in the most perfect manner, it is called a *chronometer*, and used in navigation for determining differences of longitude. [CHRONOMETER; LONGITUDE.]

Watches are said to have been made at Nuremburg so early as 1477; but it is uncertain how far the watches then constructed resembled those which now go by that name. Some of the early ones were very small, in the shape of a pear, and sometimes sunk or fitted into the top of a walking-stick. As time-keepers watches could have very little value before the application of the spiral spring as a regulator to the balance. The merit of this excellent invention has been claimed by Hooke and Huygens; but it seems established by unquestionable evidence, that the priority belonged to Hooke by at least fifteen years. The date of the invention is about the year 1658. Hooke's first balance spring was straight, and acted on the balance in a very imperfect manner; but he soon perceived its defects, and attempted to obviate them by adopting first the cylindrical, and afterwards the flat spiral. The latter appears to have been applied to watches before the publication of Huygens' claim in 1675. [HOROLOGY.]

WATCH. On Shipboard, the portion of the ship's crew on duty at a time. This is usually half; and the watches are called the *starboard* and *port* watches. Large crews are put in three watches. The period of the time called a watch is four hours, the reckoning beginning at noon or midnight. Between four o'clock and eight P.M. the time is divided into two short or *dog* watches, in order to break the constant recurrence of the watches at the same hours.

Water (Ger. wasser). The old chemists considered water as an element, and supposed it convertible into earth, and into various organic products. This opinion was first questioned, and afterwards disproved by the experiments of Watt and of Cavendish, in the years 1786 and 1787. (*Phil. Trans.*) It has since been satisfactorily demonstrated that hydrogen and oxygen are the elements of water, and that they are contained in it in the relative proportions by weight of 1 and 8, or by volume 2 and 1; the specific gravity of hydrogen being to that of oxygen as 1 to 16; 3 volumes of the mixed gases producing 2 volumes of steam, the specific gravity of which referred to hydrogen as unity is 9.

The electro-chemical decomposition of water is that which affords the most satisfactory evidence of its nature. When made part of the volta-electric circuit, it is resolved into 2 measures of hydrogen and 1 of oxygen gas, the former evolved at the negative, and the latter at the positive surface; and if the gases thus obtained be mixed, and fired by the electric spark, they again combine, and produce their weight of water. The analytic and synthetic evidence, therefore, of the composition of water is thus rendered complete.

But although perfectly pure water, such, for instance, as has been boiled and very cautiously distilled, is in fact an *oxide of hydrogen*, and composed as above stated, all natural water is more or less contaminated by foreign matters, which if not in excess, or of an uncommon or injurious nature, render it sometimes more fit for the ordinary uses to which it is applied.

The impurities present in natural water may be divided into four classes: 1. Mechanical impurities; 2. Gaseous impurities; 3. Dissolved mineral impurities; and 4. Organic impurities.

Rain water collected at a distance from inhabited places and upon insoluble surfaces of rock or sand is the purest kind of natural water. It is, however, charged with the gases of the atmosphere with which it comes in contact during its descent to the earth, viz. oxygen, nitrogen, and carbonic acid gas. The rain which falls during and after thunder storms is often found to contain very appreciable quantities of nitrate of ammonia, produced by electric discharges through moist air.

The variety of natural water which is next in purity to rain water is that of some rivers and lakes in mountainous and rocky districts, where the soil contains merely traces of soluble matters which are washed down by the abundant rain of such localities. These waters, of course, contain the same impurities as rain water, together with small quantities of mineral salts, and generally of organic matter. Then follow in purity the waters of springs and rivers, which contain very varying quantities of mineral compounds, depending, of course, on the quality of the strata through which they have passed. Lastly, the waters of the sea and of certain inland lakes contain very large quantities of mineral matters, brought down by rivers which are charged with the soluble matters of the earth's surface.

All these varieties of natural waters may be purified by carefully distilling and rejecting the first and last portions which pass over, the former containing a portion of the gases, and the latter being liable to contamination with the saline bodies originally dissolved in the water.

The four classes of impurities mentioned above differ very much in their importance with regard to the use of the water for various purposes; a glance at these may be interesting.

Mechanical Impurities.—These may be both mineral and organic. The mineral mechanical or suspended impurities are contracted by the water during its passage through the earth or over its surface, and consist principally of sand, clayey matter, chalk, and other insoluble compounds. The organic suspended impurities consist of animal and vegetable organisms, either living or dead, of animal remains and refuse, and of vegetable matter. All these impurities may be separated almost entirely by allowing the water to settle, and then pouring off the clear liquid, or more perfectly by filtration through some porous material, as unglazed paper, sponge, sand, &c.

These impurities communicate an unpleasant turbid appearance to the water, although on account of their ready removal they are not, in themselves, much to be feared; the decomposition of the animal and vegetable matters may, however, give rise to the production of compounds not only noxious, but dangerous to animal life.

Solid constituents in 100,000 *parts of various Waters supplied to Towns.*

	London				Farnham	Watford	Aberdeen	Liverpool
	New River Company	East London Company	Kent Water Company	Thames Ditton and Grand Junction Company				
Carbonate of lime	11·17	14·51	10·03	16·84	0·33	23·04	1·21	1·08

	25·24	29·85	39·50	28·74	10·36	32·45	5·71	7·45

* In all probability these numbers are too high, as the method formerly employed for the estimation of organic matters in waters gave results considerably in excess of the actual amount present.

Gaseous Impurities.—The nature of the gaseous bodies present in natural waters varies according to the localities from which they are obtained. Rain water, which has fallen at some distance from large towns, contains little more than oxygen, nitrogen, and carbonic acid gas, but that which is collected in the neighbourhood of cities, or in manufacturing districts, is liable to contamination from some of the waste products of furnaces. Waters of springs and rivers also frequently contain large quantities of gases. Some waters which have percolated

through the chalk formations appear quite milky when first drawn, owing to the minute bubbles of carbonic acid gas escaping from the liquid. Some waters, as those of Harrogate and Aix-la-Chapelle, contain notable quantities of sulphuretted hydrogen gas. Most natural waters contain a considerable quantity of oxygen, unless, from extreme pollution of the water by organic matters, the whole of the oxygen has been absorbed by these bodies.

With the exception of sulphuretted hydrogen, these gases are not deleterious; in fact, without them, neither animal nor vegetable life could be sustained in the waters, and they appear also to communicate an agreeable taste to the liquid. It was proposed many years ago to supply ships with sea water purified from its salts by distillation, but thus obtained it was found so unpalatable as a beverage that it could not be used until a means was devised for aërating it, and thus removing its unpleasant *flat* taste. The ships of the royal navy are now provided with distillatory and aërating apparatus, which render them independent of water supply from land sources.

Dissolved Mineral or Saline Impurities.—These are of the most varied description, and are contracted by the waters of springs and rivers during their passage through and over the surface of the earth. They severally constitute by far the larger proportion of the substances present in waters: their quantities and varieties will be seen from the following table, which contains the analyses of the water supplies of some towns.

Water of Loch Katrine supplied to the principal part of Glasgow.

Peroxide of iron	0·343
Lime	0·731
Magnesia	0·219
Potash	0·043
Soda	0·320
Chloride of sodium	0·017
Sulphuric acid	0·660
Phosphoric acid	trace
Carbonic acid	0·562
Silicic acid	0·176
Organic and other volatile matter	0·071
	3·142

The waters of the New River and East London companies are obtained from the river Lea; the latter company's works, however, are much farther from the source of the river than those of the former; and the different composition of the water, particularly the much larger proportion of the organic matter in that of the East London company, shows conclusively the contamination which it has undergone (from sewage and other matters) in its course towards the Thames. In other respects these waters have very similar compositions, except that in the East London the quantities of carbonate and nitrate of lime are rather higher than in that of the New River. The Kent water company draws its supply from Artesian wells, and very different results are obtained by the analysis of this water. The total amount of solid residue is very much greater than in the other two cases; and although the quantity of carbonate of lime is less than in the New River water, yet the amounts of sulphate of lime, chloride of sodium, and carbonate of magnesia, are very much increased. The Grand Junction water may be taken as a sample of the water supplied to the west and southern districts of London, and which is all taken from above Teddington lock, and therefore above the influence of the tides. In this case the total solid residue stands intermediate between that of the New River and East London water; the organic and other volatile matter is also less in quantity than in the cases of the East London and Kent companies; but the principal difference between the Grand Junction and the other waters consists in the very large quantity of carbonate of lime contained in it. The water from Farnham, which is next on the list, and with which it was once proposed to supply London, is obtained from springs from the greensand, and is far purer than the waters already mentioned. The amount of total solid residue is about one-third of that of the river waters, and one-fourth of that of the Kent company's. The water from Watford contains a very large amount of solid compounds, the chief part of which consists of carbonate of lime: the organic and other volatile matter in this case is slightly more than in the previous instances. The waters supplied to Aberdeen and Liverpool follow in the table, and stand in great contrast with the London waters, although they are inferior to the Loch Katrine water, which is remarkable for its great purity. The latter contains a quantity of solid residue about one-tenth of that of Thames water, and far less organic and other volatile matter than any on the list.

The most objectionable of the saline impurities are the salts of magnesia and lime, as they communicate to the water a *hardness* which is due to the property possessed by these compounds of decomposing soap. Soap consists principally of an alkaline salt of stearic acid, and is perfectly soluble in pure water, producing, when the solution is agitated, a froth termed *lather*, which must be formed before the detergent properties of the soap can come into action. When soap is introduced into water containing salts of lime or magnesia, double decomposition takes place, an insoluble stearate of lime or magnesia being formed which constitutes the greasy curds which are seen in all hard waters when soap has been introduced into them. The detergent action of the soap cannot, therefore, come into play until a sufficient quantity has been employed to remove the lime and magnesia from the water; when this is accomplished, a lather is formed and the soap becomes available. Besides this, the stearate of lime is precipitated in the pores of

the skin, and may even cause their stoppage, a result which must be detrimental to the healthy action of the skin. The salts of potassium and sodium present in the waters have no deleterious action on soap, and on this account the Loch Katrine water is very suitable for washing purposes, one-third of the solid residue consisting of sodium salts, a little more than one-third of organic matter, and less than one-third of calcium and magnesium compounds.

The following extract from Dr. Frankland's Report to the Registrar-General for the year 1866 will give a good indication of the composition of the water supplied to the metropolis.

Companies	Solid Matter in 100,000 parts of Water	Organic and other Volatile Matter in 100,000 parts of Water	Amount of Oxygen required for Oxidation of Organic Matter	Hardness
Water of Companies drawing from Thames	27·88	1·29	·0571	19·5
Kent Company (Artesian Well)	39·03	1·34	·0096	26·5
South Essex Company (Artesian Well) . .	38·77	1·55	·0138	25·1
New River (River Lea)	24·85	1·05	·0268	18·4
East London (do.) . .	30·48	1·42	·0474	20·4

In these analyses the results are obtained in the following manner. The amount of solid residue is determined by evaporating in a platinum dish, of known weight, a litre (or 1,000 cubic centimètres) of the water, which has been previously mixed with a quantity of a standard solution of carbonate of soda containing exactly 0·1 grm. of the carbonate. When the evaporation is complete, the dish is placed in an oil bath and heated to a temperature between 120° C. and 130° C. (248° to 266° Fahr.), and allowed to cool in dry air and rapidly weighed. This weight, *minus* the weight of the dish, and the 0·1 grm. of carbonate of soda added, gives the weight of the solid residue.

The organic and other volatile matter is estimated by carefully igniting the residue in the dish and maintaining it at a dull red heat until the organic matter is burnt off. When cool, a saturated aqueous solution of carbonic acid gas is added to the residue, in the quantity of about 20 cubic centimètres to every 0·1 grm. of carbonate of lime or magnesia present. The liquid is then evaporated, the residue heated to a temperature between 120° and 130° C., and weighed as before; the loss between the two weighings gives the amount of organic and other volatile matter present in the water.

The amount of oxygen required for the oxidation of the organic matter, is determined by mixing half a litre of the water with 15 cubic centimètres of dilute sulphuric acid (1 vol. of acid to 5 of water), and gradually adding a standard solution of permanganate of potash, until a pink colour, permanent for 10 minutes, is obtained; this observation being made through a stratum of the liquid about 12 inches in depth.

It is frequently thought that the amount of permanganate required in order to obtain this result is a certain measure of the amount of organic matter present in the water. This, however, is an error, as some organic substances, and especially living organisms, resist the action of permanganic acid to an extraordinary extent. The amount of oxygen required is supposed to indicate the more dangerous varieties of organic matter, and those from which it is advisable that the water should be as free as possible.

The hardness is determined by the soap test (proposed many years ago by Dr. Clark), which consists in adding a standard solution of soap in dilute alcohol, until on agitation a lather is produced which remains permanent for 5 minutes. The degrees of hardness first proposed by Dr. Clark, indicated the number of grains of carbonate of lime, or its equivalent, contained in one gallon of water: in the above table, the hardness is given in units of carbonate of lime in 100,000 parts of water. The total hardness is determined in the water in its original state, and the permanent hardness after boiling for half an hour; the temporary hardness is found by difference.

The carbonate of lime present in natural waters, is held in solution by an excess of carbonic acid in the form of an acid carbonate: on boiling, this compound is decomposed, carbonic acid gas being evolved, and the carbonate of lime precipitated: this carbonate constitutes the incrustation formed on the interior surfaces of boilers and other vessels, in which hard water is heated, and frequently gives rise to very great inconveniences. Boiler explosions are sometimes attributed to this deposit. Various methods have been suggested to prevent its formation: one is to introduce some sal-ammoniac into the boiler; this, by double decomposition with the carbonate of lime, produces carbonate of ammonia, which volatilises with the steam, and the very soluble chloride of calcium, which remains in the liquid condition until the water is evaporated to dryness, which of course never takes place in a boiler. Another method which prevents the precipitation of this compound on the surface of the boiler, is to introduce a quantity of potatoes. These are disintegrated, and the carbonate of lime appears to be deposited on the fibre of the vegetable, forming a flocculent matter, which remains suspended in the water, and does not adhere to the vessel.

A very elegant method of removing the carbonate of lime from water to be used for domestic purposes, has been suggested by Dr. Clark. It consists in adding a quantity of lime water or milk of lime, which, uniting with the excess of carbonic acid present, precipitates it in an insoluble condition, and removing at the same time the substance which holds the carbonate of lime in solution in the water, precipitates that quantity also:—

$$\underbrace{CaO, CO_2, HO, CO_2}_{\text{Acid carbonate of lime.}} + \underbrace{CaO, HO}_{\text{Lime.}} = \underbrace{2\,(CaO, CO_2)}_{\text{Carbonate of lime.}} + \underbrace{2\,HO}_{\text{Water.}}$$

This produces the same result as is obtained by boiling; and at one time the water supplied by some of the water companies was softened in this manner. It was found, however, to be inconvenient and expensive when applied on a large scale. It has also the disadvantage that it removes only the carbonates of lime and magnesia, leaving the earthy sulphates and chlorides, which are quite as objectionable, untouched. The following process may be usefully employed for domestic purposes. It consists in the introduction into the water of a small quantity of carbonate of soda (ordinary washing soda), which precipitates all the salts of lime and magnesia, entirely softening the water. Unfortunately, the cost of carbonate of soda prevents the application of this process on a large scale. It is necessary in this case, as well as in the lime process, to avoid adding an excess of the softening agent. In the case of lime, an excess is liable to increase the hardness which it has previously reduced; and although this does not hold good with the carbonate of soda process, yet too large a quantity of this salt produces a harshness on the skin, when the water is employed for washing purposes.

Some natural spring waters contain an abnormal quantity of mineral salts, or sometimes salts of a peculiar character; they are then called *mineral waters*. Thus some springs contain sulphate of magnesia, as the Epsom waters; and others sulphate or carbonate of iron; these are called *chalybeate* springs.

The waters of the sea and of some inland lakes which have no outlet, contain abnormal quantities of mineral constituents.

The Dead Sea is one of these, and all the water which it receives from the Jordan and other streams evaporates, leaving the saline constituents behind. The water of the Jordan contains 107·14 parts of solid constituents in 100,000 parts, and thus it is not surprising that the Dead Sea contains in the same quantity no less than 24,056 parts. Again, the Elton lake, in Russia, is a saturated solution of chloride of sodium, and during the summer it is covered with a solid crust, of which 200,000 tons are annually extracted from the lake. The water of the Dead Sea is now employed for the manufacture of bromine, of which it contains considerable quantities. The analyses of this water exhibit the most extraordinary discrepancies, due doubtless to the great length of time required for the complete mixture of the waters of the rivers with that of the lake. The following, which is about midway between the highest and lowest analyses, will give a notion of the immense quantity of salts which it contains:—

Solid constituents in 100,000 *parts of the Water of the Dead Sea.*

Chloride of calcium	2,455
Chloride of magnesium	7,822
Chloride of potassium	1,217
Chloride of sodium	12,110
Chloride of aluminium	56
Chloride of ammonium	6
Chloride of manganese	6
Chloride of iron	3
Bromide of magnesium	251
Sulphate of lime	68
Carbonate of lime	trace
Silica	trace
Nitrogenous organic substance	62
Bituminous substance	trace
	24,056

The specific gravity of the water was 1·172.

The composition of the sea is subject to slight variations, according to the circumstances of the place from which the water is obtained. The following table will serve to indicate its composition:—

Solid constituents in 100,000 *parts of Sea Water.*

	British Channel.	Mediterranean.
Chloride of sodium	2605·948	2942·4
Chloride of potassium	76·552	50·5
Chloride of magnesium	366·658	321·9
Bromide of magnesium	2·929	55·6
Sulphate of magnesia	229·578	247·7
Sulphate of lime	140·662	135·7
Carbonate of lime	3·301	11·4
Iodine	traces	—
Ammonia	traces	—
Oxide of iron	—	0·3
	3625·628	3765·5
Specific gravity	1·0274 at 15·5° C.	1·0258 at 21° C.

Organic Impurities.—We have now to consider the fourth and last class of impurities present in water; these are the soluble organic impurities which are present to a certain extent in most waters. The vegetable matters are not usually of a very deleterious character; they frequently communicate a brownish colour and a bitter taste to the water. But it is the animal matters which are most dangerous, and which may be the means of spreading contagious diseases.

The presence of organic matter may be detected in waters by evaporating to dryness and heating the residue, when a brownish mass usually results if organic matter is present. It may also sometimes be detected by its decolorising a solution of permanganate of potash as above described.

Organic matters in water may be destroyed by adding a small quantity of permanganate of potash, and boiling; but a preferable method of removing it is by percolation of the water through coarsely powdered animal charcoal. In this process it appears that the organic matters are oxidised by the surface action of the animal charcoal, which retains this property for a considerable length of time; when the action becomes less rapid, simple ignition restores the charcoal to its energetic condition.

In connection with water supply, there is one important subject which must not be overlooked,

i. e. the powerful action that certain waters exercise on lead. Pure distilled water when brought in contact with lead very rapidly attacks it, the liquid being soon filled with fine crystals of a basic carbonate of lead. Thames water, and most spring and river waters, are quite destitute of this action; and it was long thought that the salts present in the water acted in a protecting manner on the metal. When it was suggested to supply Glasgow with water from Loch Katrine, great objections were raised to the scheme on account of the fact that the water of Loch Katrine powerfully affected lead, and it was thought that a large amount of poisoning would ensue from its use. Notwithstanding the opposition, the project was completed, and no trace of lead is found in the water and as supplied to Glasgow it is quite free from action on the metal. It appears that during its transit from Loch Katrine it absorbs carbonic acid gas from the air; and experiment shows that distilled water, containing in solution a sufficient amount of carbonic acid gas, is quite incapable of exerting any dangerous action on lead. This supply of carbonic acid is always obtained during the passage of water through a long conduit, and therefore no danger on this score would be involved in the supply of London, even with distilled water, if it were brought from Wales or Cumberland. [WATER SUPPLY.]

Water Bailiff. An officer in port towns, whose duties in general relate to the searching of ships: in London he has also the supervision of the fish market, gathering of tolls, &c.

Water Chestnut. One of the names for the fruits of *Trapa natans*, and other species of this genus of *Haloragaceæ*.

Water Clock. [CLEPSYDRA.]

Water Crane. A swivelling pipe employed for filling the feeding tank of a locomotive engine with water. The appearance of this pipe resembles that of a crane for lifting goods, and it is swivelled over the line, so that the mouth of the pipe comes over the tank of the locomotive, and thus, by opening a valve, water runs into the tank from an elevated cistern at the side of the railway. [RAILROADS.]

Water of Crystallisation. Some crystallised salts contain more or less water, which, as it bears a definite proportion to the other components of the salt, may be considered as one of its essential constituents. Crystallised sulphate of lime, for instance, is a compound of 68 of dry sulphate and 18 water, or of one equivalent of anhydrous salt and two equivalents of water; one equivalent of crystallised sulphate of magnesia $=123$ contains 7 of water $=63$; and an equivalent of crystallised sulphate of soda $=162$ contains 10 of water $=90$; the equivalent of water being 9. But it does not necessarily follow that a salt in crystals contains water, there being many crystals which are *anhydrous*, such as nitre, sulphate of potash, &c.

Water Devil. A name given by some micrographers to the larva of a British species of *Hydrophilus*.

Water Drops. Rounded pebbles of clear and limpid colourless Topaz.

Water Gauge. A contrivance for ascertaining the height of the water within a steam boiler. Among the expedients adopted for this purpose, one is a series of cocks, usually three, set one above the other in the front of the boiler: the lowest of these cocks should always let out water, and the highest should let out steam. Another expedient is a glass tube set vertically in the front of the boiler; the top of the tube communicating with the steam, and the bottom with the water within the boiler. The water in the tube consequently stands at the same height as the water within the boiler, and so indicates the level. Both of these contrivances are applied to most modern boilers. Another expedient sometimes used is a cock, capable of swilling round its axis in the front of the boiler, so as to bring a piece of pipe attached to its inner end, into the water, when the cock will blow water; the amount of swivelling required for this purpose indicates the position of the water level. In some boilers the height of the water is indicated by a buoy or float, placed on the surface of the water, and communicating with an index outside.

Water Meadows. Meadows capable of being kept in a state of fertility by being flooded with water from some adjoining river or stream. [IRRIGATION.]

Water Meter. An instrument for measuring the quantity of water which passes through it. Some water meters are constructed on the principle of a cylinder and piston, and each cylinder full of water that passes is registered by appropriate mechanism. Other kinds are formed on the principle of a patent log or windmill, by which the velocity of the water in the pipe is registered. No water meter hitherto introduced is free from objections, or has received wide acceptation.

Water Mill. A machine, driven by the reaction of water, sometimes called a *Barker's mill*. The most effective mill of this kind is that known as Whitelaw and Stirratt's, in which the velocity is governed by valves applied to the orifices of efflux to vary their size, thus correspondingly changing the quantity of water passing through the machine. These orifices are situated on the opposite sides of two revolving arms, and the velocity of rotation of these orifices should be made as nearly as possible the same as the velocity of the issuing water. The water is conducted into the horizontal revolving arms from below, through a watertight joint, and the upward pressure of the water balances the weight of the arms. In some cases the arms have been made in the form of an Archimedean spiral, but any other form does as well; the main condition being that the area of the arms shall be large relatively with that of the orifices. The water mill has been superseded to a great extent by the TURBINE.

Water Sapphire. A very pale-blue kind of Oriental Sapphire.

Water Supply. In Practical Geology, the quantity of water falling on any district in the form of rain, and finding its way to the interior of the earth in such a manner that it can afterwards be obtained and utilised. [SPRINGS, ARTESIAN; SPRINGS, NATURAL.]

It will be evident that the water supply must depend partly on the actual rainfall, partly on the fall of the ground, partly on the stratification of the rocks at their outcrop in the district, and partly on the nature of the rocks in the interior of the earth. Sands are always permeable in every part, but sandstones vary greatly; some being very open from cracks and bedding, others very tight and compact. Limestones are usually sufficiently cracked and broken near the surface to allow of much water to percolate, and within the earth they are almost always open, having many cavities and open fissures communicating with each other. Clays are almost always impermeable. They allow the water to run over them, and keep it back or conduct it according to circumstances.

The water supply of a district may be calculated within certain limits; but the calculation is liable to error, from the impossibility of knowing accurately the conditions of the earth's interior.

The supply of an abundant quantity of pure water to towns and cities has become one of the most important topics which can engage public attention. The connection of purity of the water used for domestic purposes with the condition of the public health has been proved most conclusively; and it is found that the ravages of epidemic disease in any district, and more especially of cholera, are wide-spread and fatal very nearly in the proportion of the impurity of water, especially in organic contamination, supplied for the use of the inhabitants. Up to the beginning of the present century, although water works existed in London and other great cities, most of the water required for the domestic uses of the inhabitants of towns, was drawn from wells by means of pumps, and even in London many public pumps still exist. But the changes in our domestic habits, which involved the construction of sewers for conducting away the refuse from every house, led to the contamination of the wells by infiltration from the sewers, and in most towns water is now supplied to the houses through pipes, by water works constructed for that purpose. The sources of supply, however, of most of these water works, are liable to contamination from the admixture of sewage; for many water works draw their supplies from rivers polluted by the sewage of towns situated higher up on the stream. Thus the water drawn from the Thames at Thames Ditton for the supply of a part of London has, before its arrival at that point, been polluted by the sewage of Oxford and other towns, and there are very few rivers in the country from which pure water can now be drawn. Even the water from many springs does not escape pollution from the infiltration of the rain which has passed through the manure spread over cultivated fields, and it consequently becomes important to derive the water required for the supply of towns from rocky or sandy districts bare of vegetation, where cultivation is not carried on. It is at the same time highly important that a comprehensive system of water works, embracing the whole kingdom, should be mapped out, to the end that the wants of the whole community may be represented, and that the same source of supply may not be fought for by several conflicting parties. Thus a scheme has been propounded for supplying Hull, and several other towns, with water from the lakes of Cumberland. But another scheme has been propounded for appropriating the water from those lakes to the supply of London. It is quite indispensable that London should be supplied from some pure and adequate source. But it is equally necessary that the claims of other districts should be considered; and it behoves the government, in the interest of the whole nation, to direct a survey to be made, which shall discover the natural and most eligible sources of supply for every town and city, and which other towns or cities, looking merely to their own local interests, should not be permitted to invade. There can be no doubt that as the water derived from the fall of rain on cultivated districts is impure, and as the area of rocky and arenaceous ground in the country is limited, the rain which falls upon those districts must not be suffered to run to waste in wet seasons, but must be impounded by the construction of great dams at suitable points of the valleys, so as to form reservoirs, or artificial lakes, in which the superfluous rainfall may be stored up. It is quite necessary that this question should now be dealt with in a practical and comprehensive manner. It behoves us to understand that the quantity of rain water which is free from contamination of some kind or other is no larger than we require, and that if it is to be sufficient for our uses it must be employed with judgment and economy. The habits incident to an advancing civilisation involve continually the consumption of a larger amount of water per head of the population, while manufactories, baths and washhouses, fountains, water for washing and watering the streets, as well as for working hydraulic cranes for hoisting goods, and for driving purposes generally, must also be taken into account in carrying out a system of water works.

In many of the towns of England, as well as on the Continent, the question of a larger and better supply of water is exciting much anxious thought. Liverpool and Hull, Paris, Florence, Berlin, Vienna and Leipsic are all either contemplating or prosecuting works having that end in view; and two great schemes have been propounded for the better supply of London, in one of which it is proposed to bring the water from the flanks of Cader Idris and Plynlimmon in North Wales, and in the other from the Cumberland or Westmoreland lakes. In

1850 the Board of Health reported that the total quantity of water delivered to London by the water companies was a little over 40,000,000 gallons per day. In 1856 the daily delivery was 81,000,000 gallons. In 1852, Acts of Parliament were passed which authorised the withdrawal from the Thames of 100,000,000 gallons daily, and it is believed that the amount now abstracted from the river is on an average about 60,000,000 gallons. In 1865 it is estimated that the eight London water companies delivered 108,000,000 gallons to 470,000 houses through 3,290 miles of pipes. This quantity of water, however, is quite insufficient for the legitimate wants of the inhabitants. In 1838 the quantity of water supplied to Glasgow by the old water works amounted to 26 gallons per head of the population. But in 1864, after the Gorbals and Loch Katrine gravitation works had been for some years in operation, the daily supply to a population of 485,000 persons was 22,500,000 gallons, or about 46 gallons per head of the population. The population of London in 1866, within a radius of fifteen miles from Charing Cross, was about 3,500,000; and if we take 50 gallons of water per head of the population as a fair allowance, the daily consumption should be 175,000,000 gallons; and making allowance for the rapid increase of population, no scheme proposing to supply less than 200,000,000 gallons daily could be considered adequate, and there must be means for increasing the supply to 250,000,000 gallons daily at no very distant period. The total quantity of water in the Thames which passed over Teddington weir in the dry season of 1864, was 380,000,000 gallons daily; so that for the water supply of London it is plain that a good-sized river of pure water is required.

In Mr. Bateman's scheme for supplying London with water from North Wales, the rainfall, though ascertained to be 45 inches in dry seasons, is taken at only 36 inches, and the drainage area consists of 130,572 acres, in two districts, of which the northern, consisting of 66,380 acres, is situated on the mountain range which includes the summits of Cader Idris and Aran Mowddy, and contains the sources of the Banw and Vyrnwy rivers, while the southern district, with an area of 64,192 acres, contains the source of the Severn. On the Vyrnwy it is proposed to form, by an embankment 76 feet high, a lake or great reservoir that will contain over 1,000,000,000 cubic feet of water, while on the river Banw two reservoirs are to be formed, one four miles long, with an embankment 80 feet high, containing 940,000,000 cubic feet, and the other, with a similar embankment, 732,000,000 cubic feet. To receive the drainage of the southern district there will be several reservoirs, of which the principal one, with an embankment 75 feet high, will contain 2,230,000,000 cubic feet of water. The total annual rainfall on these districts will be about 632,000,000 cubic yards, or about 104,000,000 gallons per day. But the aqueduct will be made capable of transmitting 220,000,000 gallons daily. The discharge pipes of the lowest reservoirs will be situated 450 feet above Trinity high-water mark.

The waters will be conducted by separate aqueducts to a point near Marten Mere, where they will be joined to a larger aqueduct running past Bridgenorth, Warwick, Banbury, Buckingham, and Watford, and terminating in large service reservoirs situated on the high ground near Stanmore. These reservoirs, which will be sufficiently large to hold ten days' supply, will be 250 feet above high-water mark, and from them the water will be conducted in pipes to London. The length of the branch aqueduct from the northern district to Marten Mere will be 19 miles, from the southern district to Marten Mere 21½ miles, and from Marten Mere to Stanmore 152 miles. The two branch aqueducts will each be capable of conveying 130,000,000 gallons daily, and the main aqueduct 220,000,000 gallons daily, as we have already stated. The area of the collecting ground can be increased wherever it may be found necessary. But it would be better to have this area large at once, and then to increase the supply by constructing reservoirs instead of by taking in more land, for which high terms might be required if left till it had become indispensable. At Bridgenorth the aqueduct will be carried across the Severn by means of siphon pipes, and the same expedient will be adopted for crossing the valleys of other rivers which the aqueduct has to pass. Between Bridgenorth and Watford the aqueduct will consist partly of open excavation and partly of tunnel or covered way, and its course will be such as to avoid the coalfields near the route, and also the salt-beds of Droitwich, to the north of which it will pass. The fall of the open portion will be 6 inches per mile, and of the covered portion 14 inches per mile. The total distance to be traversed by the water from the lowest reservoir on the Cader Idris branch before reaching London is 181 miles, and from the lowest reservoir on the Plynlimmon branch 183½ miles. The cost of the undertaking is estimated by Mr. Bateman at 8,600,000*l.*, of which over 1,000,000*l.* will be required for the construction of each of the branch aqueducts and its reservoirs, while the remainder will be required for the main aqueduct, the service reservoirs, and the connection of the pipes of the existing water companies with the new source of supply. The water in softness and purity is nearly the same as that supplied to Glasgow from Loch Katrine. The cost of new water works at Liverpool has been about 75,000*l.* for each 1,000,000 gallons per day delivered; at Manchester, 34,000*l.*; and at Glasgow, 45,000*l.* But if the sums which have been paid to previously existing companies be added, the amounts will rise to 115,115*l.*, 60,000*l.*, and 59,260*l.* respectively. The estimated cost of the proposed London works is 71,000*l.* per 1,000,000 gallons delivered daily so long as the delivery is 120,000,000. But it would

fall to 49,300*l.* when the full quantity which the aqueduct could transmit was supplied. Mr. Bateman considers that the capital required to construct the work might probably be raised at 4 per cent., that the management and repairs would cost 150,000*l.* per annum, and that 450,000*l.* per annum would pay their existing dividends to the existing water companies, making a total annual expense of 944,000*l.*, while a compulsory domestic rate of 10*d.* in the pound on the value of 12,000,000*l.* worth of dwelling-houses, and a public rate of 2*d.* on 18,000,000*l.*, with a revenue of 250,000*l.* per annum for the sale of water for trading purposes, and an annual value of 50,000*l.* of surplus property of existing companies which are to be absorbed, would make up a yearly income of 950,000*l.* At Manchester the rates now levied are 9*d.* in the pound for the domestic rate, and 3*d.* in the pound for the public rate.

In Messrs. Hemans and Hassard's scheme it is proposed to draw the supply from the Cumberland lakes, 240 miles distant, and to deliver it in London at a height of 220 feet above high-water mark. The area from which the water is to be collected is 177 square miles in extent, and of a mean altitude of 1,300 or 1,400 feet above the level of the sea. The whole district is bare hill pasture, and with the exception of a small area in the vicinity of Ullswater, which can easily be excluded from the scheme, is without mineral deposits. The mean annual rainfall is 100½ inches, but is taken at 80 inches, and the collecting area drains into the rivers Lowther and Greta, and into the lakes Haweswater, Ullswater, and Thirlmere. Storage would be provided in the lakes and in artificial works for over 5,000,000,000 gallons, or 120 days' supply at 250,000,000 gallons per day. From Ullswater the water would be drawn off through a tunnel 7¼ miles in length, which would be the only work of magnitude connected with the undertaking, and which would, it is estimated, be completed in about three years. The water would be conveyed to London by conduct tunnel and iron pipes, and would run nearly parallel with the North-Western Railway, delivering the water in a large reservoir at Harrow. The cost of the scheme for a daily supply of 250,000,000 gallons is set down as 12,200,000*l.* About 50,000,000 gallons, it is expected, would be disposed of to the towns on the line.

It must be remembered, however, that Mr. Dale, of the Hull corporation water works, proposes to employ the water of the Cumberland lakes to supply the towns in the north of England. Mr. Dale proposes to draw 150,000,000 gallons daily from these lakes through four cast-iron pipes of 6 feet diameter, which would extend as far as Leeds, 90 miles; three lines thence to Bolton, 55 miles; and two lines thence to Liverpool, 25 miles. Halifax, the highest town to be supplied, is 604 feet above the sea, Rochdale 472 feet, Burnley 492 feet, Huddersfield 429 feet, Bradford 420 feet, Keighley 388 feet, Blackburn 373 feet, Bolton 337 feet, Kendal 316 feet, Bingley 278 feet, Leeds 300 feet, Liverpool 227 feet, Wakefield 201 feet, Dewsbury 187 feet, Wigan 157 feet, Preston 140 feet, and Lancaster 132 feet. Mr. Dale's scheme, though sketched out at the end of 1865, was not published in detail till the end of September 1866, before which time Messrs. Hemans and Hassard's project had appeared.

It would be impossible within the limits of this article to notice in any detail the many important water works which are at present engaging public attention in the districts to which they belong; but we may remark that the water works of Paris embody a principle which may be carried out with advantage in every case where it is not easy to obtain large supplies of good water. There are two water services, the one of spring water for domestic, and the other of river water for watering and cleansing the streets, and for all other purposes for which it is suitable. Paris, with a population of 1,700,000 inhabitants, receives a supply of 240,000 cubic mètres, or 53,000,000 gallons per day, being about 31 gallons per day for each inhabitant. A further supply of 16,000 cubic mètres per day is expected so soon as the works which transmit the water of the river Dhuys are completed, and to this about 196,000 cubic mètres per day will, it is supposed, be added by bringing water from the sources of the Vanne, by pumping water from the Marne, and by sinking two new Artesian wells. Each street in Paris is by this system supplied by two different classes of pipes, an arrangement which might well be imitated in London; and if good water be brought from a distance to be transmitted through the existing pipes, the water of the existing water companies might be employed, when transmitted through a duplicate system of pipes, to perform all the functions which in Paris are performed by the river-water service.

The water of the Dhuys is brought to Paris by an aqueduct 134,000 mètres in length, of which part is a brick culvert, and part cast-iron pipes. The culvert, of which the cross section resembles an egg with the broad end downwards, is 1·4 mètre broad, and 1·76 mètre high. The principal source of the spring water is the Dhuys, the other sources being the springs of Arceuil, collected in the reservoir of the Pantheon and the Artesian well of Grenelle. The supply of river or coarser water is obtained by pumping from the canal of the Ourcq, and from the rivers Seine and Marne.

One of the most important points connected with the supply of water to towns consists in the accurate determination of the volumes of water which a given pipe or aqueduct with a given head or fall will transmit. The hydraulic mean depth of a stream is the area of the cross section, divided by the wetted perimeter; and if R be the hydraulic mean depth of the water in an aqueduct, I the inclination or declivity of the bed per foot run, and V the velocity of the water in feet per second, then $RI = aV + bV^2$, where a and b are constants determined by ex-

periment. Eytelwein has shown that the mean velocity of water flowing through uniform channels is very nearly $\frac{10}{11}$ that of a mean proportional between the hydraulic mean depth, and twice the fall in feet per English mile. If therefore H be the head or fall in feet per mile, then $V = \frac{10}{11}\sqrt{2RH}$. The velocity in feet per minute will be 60 times this, or it will be 54·54 times the amount obtained by multiplying the hydraulic mean depth by twice the fall in feet per mile. Mr. Beardmore in his Hydraulic Tables uses the coefficient 55 instead of 54·54. His rule is as follows:—

To determine the mean velocity with which water will flow through aqueducts, arterial drains, or pipes running partly or wholly filled:—

Rule. Multiply the hydraulic mean depth in feet by twice the fall in feet per mile; take the square root of the product, and multiply it by 55. The result is the mean velocity of the stream in feet per minute.

This again, multiplied by the sectional area in square feet, gives the discharge in cubic feet per minute.

In cylindrical pipes running full, the hydraulic mean depth is one-fourth of the diameter. For the hydraulic mean depth, being the area divided by the wetted perimeter, is in a full pipe $\frac{\cdot 7854\, d^2}{3\cdot 1416\, d} = \frac{d}{4}$.

M. Prony has shown, by comparing a large number of experiments, that if H be the head in feet per mile required to balance the friction, V the velocity of the water through the pipe in feet per second, and D the diameter of the pipe in feet, then $H = \frac{2\cdot 25\, V^2}{D}$.

This equation is identical with that used by Boulton and Watt since the commencement of the present century, and which is as follows:—

If l be the line of the main in miles, V the velocity of the water in the main in feet per second, D the diameter of the pipe in feet, and 2·25 a constant, then the head of water in feet necessary to overcome the friction will be $\frac{2\cdot 25\, l V^2}{D}$; in other words, there must be the number of feet in height of water indicated by this expression at one end of the pipe over the height at the other end to cause the water to run at the assumed velocity of flow. [Sewage; Water Meter; Water Works.]

Water Table. In Architecture, a projection or horizontal set-off in a wall, so placed as to throw off the water from the building.

Water Tables. In a ship, the sills of the windows in the stern.

Water Ways. Strong pieces of wood extending round the ship at the junction of the decks with the sides, to prevent the water entering between the edge of the deck and the ship's side; and also to counteract any tendency in the beams to slip upwards.

Water Wheel. In Hydraulics, an engine for raising water in large quantities. [Persian Wheel.] Also a wheel turned by the force of running water. Of these there are three kinds: the *undershot wheel*, the *overshot wheel*, and the *breast wheel*. In the case of the undershot wheel, the water strikes the float boards below the axle, and acts by the impulse due to its velocity. In the case of the overshot wheel, the water is brought over the top of the wheel, is received in buckets, and acts solely by its weight. In the case of the breast wheel, the water is received about midway up on the wheel, and acts chiefly by its weight, the float boards being made to run in a circular arc, which prevents the water from being spilt. Good overshot water wheels realise about 80 per cent. of the theoretical power of the water. But they are inconvenient from their large dimensions, especially in the case of high falls, and the turbine is now usually preferred. Breast wheels, if made with curved float boards on Poncelet's construction, are nearly as effective as overshot wheels.

Water Works. Works for supplying towns with water. The water is sometimes conducted at a high level from an elevated source by means of an aqueduct, and sometimes is pumped up from a well or river by a steam engine either into an elevated reservoir or directly into the distributing pipes. The pipe which conducts the water from the pump to the reservoir is called the *rising main*. In many water works a pipe called a *stand pipe* is introduced to supply water to houses standing at a higher level than the reservoir, the water being forced up into this pipe by the engine, while any excess not drawn off flows over through a bend into another upright pipe of the same height, and so escapes. In some water works there is no elevated reservoir, but the necessary hydrostatic pressure is obtained by forcing the water up into the stand pipe to the requisite height; in other cases, instead of a stand pipe, a safety valve properly loaded allows any excess of water to escape after the standard pressure has been reached. The engines for water works are now almost always double-acting rotative engines, and the pumps are usually of the bucket-and-plunger kind, first introduced by Mr. David Thomson in the Richmond water works in 1840. [Water Supply.]

Water-colour Painting. A species of painting or drawing, in which the medium of representation is colour levigated with water and gum, and which in our days has been carried to extraordinary perfection. Formerly all decorative work or limning was done in water-colours, i. e. the colours were tempered with a water vehicle, as gum, egg, size, or glue, milk, fig-sap, &c. These methods are, however, *tempera* or distemper methods, not pure water-colour painting, as in every case a *binder* is added to the water. Fresco, on the contrary, is a pure water-colour painting; so is also the new method of waterglass. [Fresco; Waterglass.] Not only all illumination or limning of manuscripts was executed in water-colours, but easel pictures also and large altar-pieces were executed in water in the middle

ages, and until the fifteenth century, when the old *tempera* vehicle was superseded by the varnish method of the Van Eycks, now commonly called *oil-painting*. Distilled water or filtered rain-water should be used; and gall and alcohol are also very serviceable; saccharine matter should be avoided, as it attracts the damp. [PAINTING.] On the best colours for water-painting, see Field's *Chromatography, or a Treatise on Colours and Pigments, and of their Powers in Painting*, 8vo. London 1841.

Water-cure. [HYDROPATHY.]

Water-lily. The common name for the species of *Nymphæa* and *Nuphar*, found in many of our streams, and greatly admired, especially the former, for its chaste beauty. An allied plant found in the waters of Guiana, called *Victoria regia* by botanists, is often called the royal water-lily.

Water-line. The boundary of any section of the bottom of a ship made by a plane parallel to the line of flotation. The uppermost one is called the *load water-line*; the lowest the *light water-line*.

Water-logged. A Nautical term, denoting the state of a ship when a quantity of water having been received into the hold by leaking, &c. she has lost her buoyancy, and yields to the effect of every wave passing over the deck.

Water-shed (Ger. wasserscheide, *water-parting*; the word *shed* is still used in Lincolnshire in the sense of *parting* or *dividing*). In Physical Geography, the natural surface drainage of a tract of land is grouped into a series of areas, called *river basins* or *drainage areas*, each of which is connected with some stream that enters the ocean or an inland sea. The dividing lines between such areas are called the *water-shed* or *water-parting*. It is not always the case, though most usual, that this line runs along a high ridge. It may cross a perfectly level tract or even a sheet of water. In South America the waters of two great drainage areas sometimes, but rarely, anastomose.

Water-weed. A name by which the *Anacharis Alsinastrum*, a pest of navigable streams, is sometimes known.

Watercress. A semi-aquatic herb found wild by the sides of brooks and in ditches, and much cultivated as a salad plant, especially for the supply of large towns, on account of its antiscorbutic properties. It is the *Nasturtium officinale*, and belongs to the order of Crucifers, many of which possess similar properties.

Waterfalls. Rivers in their course to the sea occasionally pass over rapid declivities, and sometimes fall over ledges of rock or precipices. Very frequently these have been originally produced or greatly increased and modified by the eroding action of the river itself. These are called *rapids* or *waterfalls*, as the water runs over obstacles on a slope or leaps down a precipice.

The most celebrated waterfalls in Europe are undoubtedly those of the Rhine, about two miles below Schaffhausen in Switzerland. The fame of these falls is, however, chiefly owing to the celebrity of the river, and to the mass of the stream, as the height is not great, varying from 50 to 60 feet according to the season. Other renowned waterfalls in Switzerland are: those of Handeck in the Oberhasli valley, where the Aar 'descends at a single bound of 200 feet into a dark chasm, whence clouds of spray ceaselessly arise, as if driven up by blasts from some subterraneous cavern;' and of the Staubbach, near Lauterbrunnen, a single shoot of about 900 feet. The fall of Gavarnie, in the Pyrenees, exceeds this in total height, but is broken on an intermediate ledge. On the whole, however, the falls of the Ache, near Krimml, on the boundary between Saltzburg and Tyrol, may be considered as the finest in the Alps; the stream, which has a considerable body of water, shoots down a height of about 2,000 feet in four leaps, the upper fall being one of about 700 feet. In Northern Europe the most celebrated falls are the Sarp-fos in Norway; the river Hommers, 120 feet wide, 27 feet deep, fall 75 feet; the Riukan-fos, 900 feet; and the Ostud-fos, 700 feet.

In Asia no very important falls have been described. In Africa the falls of the Zambesi are very remarkable. The river, which is large, leaps 100 feet into a ravine. The Ripon Falls, by which the Victoria Nile makes its way from the Victoria Nyanza to the Albert Nyanza, are very grand. The total difference of level is 600 feet. The Murchison falls of the Nile involve a leap of 120 feet, where the river is 50 yards wide and very deep.

In America the falls of Niagara are the most remarkable. The river is divided by an island. The American side is 375 yards wide, and the fall is 162 feet. The Canada fall is 700 yards wide and 149 feet deep. There are other important falls in the northern rivers, but none so considerable as these.

Waterglass. In Painting, a method of colouring lately discovered and established in Germany as a substitute for fresco. It is especially applicable for wall-painting. It is a pure water-colour painting on a porous or absorbent ground, of white plaster. After the wall is prepared with Portland cement and sand, it is covered with an intonaco or thin coat of fine plaster, containing three parts of fine sand—composed of carbonate of lime—and one of cement; this intonaco should be evenly worked by the mason, with a kind of tooth in the surface, by the use of a wooden hand float. The intonaco may be three of fine quartz sand and one of lime, such as is used in fresco-painting. The design may be traced on the wall when properly hardened; but the wall should be moistened immediately before painting. The colours are applied, mixed with distilled water, not heavily or in any great body, but thinly hatched over the surface. When the picture is finished, the whole is fixed by an application of the so-called *waterglass* from a syringe made expressly for the purpose, called a *sprinkler*.

The picture is thus indelibly fixed; hence the term *stereochromy*. Waterglass is a soluble alkaline silicate, a liquified flint, made by boiling silica in an alkali: it is sold in a liquid state, and is applied mixed with twice its quantity of water, one quart of the mixture being required to fix twenty square feet of painting. There are two kinds of waterglass, the one made with soda, the other with potash; the latter is found to be preferable. A picture thus fixed has no gloss, and can be seen in all lights. This method has been already successfully applied in the Houses of Parliament. (*Twelfth Report of the Commissioners on the Fine Arts*, 1861.)

Watering of Stuffs. This is a process to which silk and some other woven fabrics are subjected, in order to give a peculiar appearance to their surface, as seen by reflected light: it is generally done by passing the goods, in a damped state, between rollers, some of which are variously indented or engraved: sometimes the appearance depends upon the pressure of one fold of the stuff laid transversely or diagonally upon another, and powerfully pressed between plain revolving cylinders.

Waterlandians. In Ecclesiastical History, a division of the Dutch Anabaptists, also called *Gross* (Grob), or *Moderate*, in contradistinction to the *Fine*, or *Rigid*. They were so called from a district in North Holland denominated Waterland, and originated in the sixteenth century. John de Ries, in 1580, composed a confession of faith, which seems to have been pretty generally used among them. [GALENISTS; MENNONITES.]

Waterproofing. The process by which textile fabrics are rendered impervious to water. This is most perfectly effected by means of caoutchouc, which is applied in various ways; but there are other substances, and among them some of the earthy soaps, which are more or less effective, such, for instance, as a mixed solution of soap and alum, to which some gelatinous material is occasionally added.

Waterspout. A very remarkable meteorological phenomenon, observed for the most part at sea, but sometimes also on shore, though generally in the neighbourhood of water. Its general appearance may be described as follows: from a dense cloud, a conical pillar, which appears to consist of condensed vapour, is seen to descend, with the apex downwards. When over the sea, there are usually two cones; one projecting from the cloud, and the other from the water below it. These sometimes unite, and the junction has been observed to be accompanied with a flash of lightning; but more frequently they disperse before the junction is effected. In calm weather the column maintains its vertical position while carried along the surface; but when acted on by the wind it becomes oblique to the horizon. The causes of this meteor are very imperfectly known. By some it is supposed to be formed by a whirlwind of extreme intensity, while others ascribe it to an electric origin. (Young, *Nat. Phil.* vol. i.; Pouillet, *Elémens de Physique*, tome ii.) They are probably occasioned by the whirling of air with such velocity as to cause a vacuum in the axis of rotation; the contact of the lower end of such a vertical axis with water would cause the elevation of a column of the latter to a height of about thirty feet.

Wave (A.-Sax. wæg). The alternate elevation and depression of parts of the surface of a liquid above and below the natural level.

When the surface of a liquid is unequally pressed, the columns which sustain the greatest pressure are shortened, and sink below the original level; and the contiguous columns, being affected by the same pressure, will be lengthened and rise above that level. But as the elevation is not sustained by an hydraulic pressure, the lengthened columns again fall, and acquiring in the fall a velocity due to the height, descend below the original level, communicating in their turn a pressure to those which are adjacent to them. In this manner a reciprocating motion is produced, the particles to which the primitive impulse was communicated being alternately the lowest and the highest; the result is a series of ridges and hollows called *waves* or *undulations*.

In passing from the columns which are shortened to those which are lengthened, and back again to those to which they originally belonged, the particles of the fluid acquire both a vertical and horizontal motion; but while the depth is sufficient to allow the oscillations to proceed unimpeded, no progressive motion takes place, each column being kept in its place by the pressure of the surrounding columns. If, however, free oscillation be prevented (as by the shelving of the shore, or the interposition of a rock), the columns in the deep water are not balanced by those in the shallower, and thus they acquire a progressive motion towards the latter, or form *breakers*. For this reason, waves always break against the shore, whatever be the direction of the wind.

When waves are produced by the agitation of a small portion of the fluid, as for example by throwing a stone into stagnant water, they appear to advance from the disturbed point in expanding concentric circles, the height of the wave gradually diminishing as it recedes from the centre; but that there is no transference of any part of the mass from one place to another, is manifest from the motions of any light body floating on the surface. The appearance of progression is in fact an optical deception, produced by the form of the wave and the mode of oscillation. On attending closely to the phenomena it will be seen that the fore part is always in the act of rising, and the hinder part in the act of falling; and thus the whole system appears to roll onwards, while each particle of water in succession merely oscillates with a vertical ascent and descent.

If a second series of concentric waves takes

its origin from a different point at some distance from the first, the two sets will cross each other without the slightest interruption. Where a wave of the first series meets one of the second, and the two elevations correspond, the resulting elevation will be equal to the sum of the two; and the same is the case with the depressions. Where the elevation in the one series corresponds with a depression in the other, the surface will maintain its original level, at least if the waves of the two series have the same height. Thus, although different series of waves do not interfere with each other's propagation, they may nevertheless increase or neutralise each other's effects. The one series is, in fact, superposed on the other.

A series of waves meeting a vertical obstacle, as a wall or bank, is reflected; and the reflected waves are propagated in the same manner as those arising from the original impulse, but in an opposite direction. Waves proceeding in concentric circles are reflected in concentric circles, in such a manner as to diverge apparently from a centre as far behind the obstacle as the original centre is in front of it; they appear, in short, to be subjected to all those laws which are usually noticed to belong to reflected light.

If the obstacle against which the waves strike have an opening in it of small horizontal breadth relatively to the breadth of the wave, the oscillating columns which reach it will act as an impulse originally exerted at that point, and a series of waves will diverge from the aperture as from a new centre; but when the aperture is considerably wider than the wave, the wave confines its motion in a great measure to its original direction, though with some small divergence, or the oscillation is continued principally in the direction of a sector, whose centre is at the point from which the original wave proceeded.

Waves which have been raised by the wind in the open sea proceed in parallel and nearly straight lines; and the original impulse being increased by the continual action of the wind, they will increase in height until the weight of the elevated column, together with the friction, becomes equal to the inciting cause. It has been inferred that the greatest height to which a single series of waves raised by the wind blowing constantly in one direction will attain does not exceed six feet. But several series of waves moving with different velocities may co-exist upon the ocean, and thus the crests of two or even three waves may be superimposed upon each other, producing the *tremendous seas*, three of which are usually succeeded by comparatively smooth water, because the hollows of the one series are then filled up by the crests of the other. The force of the wind also tends to give a progressive motion to the mass of water raised above the general level, and likewise to alter the shape of the wave by diminishing the acclivity of the side against which it strikes. In a strong gale this effect may be increased so far as to cause the top of the wave to project over the base, in which case it breaks and rolls over on the preceding wave. Hence, as sailors well know, a very strong wind will blow the sea down.

If the wind, after having given rise to a series of waves, suddenly veers about so as to strike waves on the opposite side, it will produce a greater effect from its more direct impact; and hence the greatest waves are produced by sudden changes of wind, or by the wind blowing in an opposite direction to that in which the waves are propagated. In this manner the elevation of the waves may be greatly increased above the height to which they would be raised by winds of equal force blowing constantly in the same direction. Hence the ocean is comparatively smooth in regions where the winds are constant; and as it is by the friction of the wind on the water that the waves are raised and kept up, whatever diminishes the friction will tend to lessen the elevation. Hence the comparative tranquillity produced by pouring oil on agitated water.

Wave-offering. In the Old Testament (Ex. xxix., Lev., and Num.), an offering which when held aloft by the priest was *waved*, signifying symbolically that it might be eaten by the worshippers: whereas such as were *heaved* were appropriated to the priests.

Wavellite. A hydrated phosphate of alumina, found generally in small crystals forming hemispherical or globular concretions with a radiated structure. It is met with at St. Austell in Cornwall, on the clay-slate of Barnstaple in Devonshire, near Freiberg in Saxony, in Bohemia, &c. It is named after Dr. Wavell, the discoverer.

Wax (A.-Sax. wæx, Ger. wachs). This is a common vegetable product, forming the varnish which coats the leaves of certain plants and trees. It is also found upon some berries, as of the *Myrica cerifera*; and it is an ingredient of the pollen of flowers. It was long supposed that bees merely collected the wax thus ready formed in plants; but Huber found that though excluded from all food except sugar, they still formed wax; and accordingly it has been found that the elementary composition of bees' wax and vegetable wax is slightly different. Bees' wax is prepared by draining and washing the honeycomb, which is then melted in boiling water, strained, and cast into cakes. English wax and foreign wax are found in the market; the latter being chiefly imported from the Baltic, the Levant, and the coast of Barbary. Fresh wax has a peculiar honey-like odour: its specific gravity is ·96. At about 150° it fuses, and at a high temperature volatilises, and burns with a bright white flame. It is bleached by being exposed in thin slices or ribands to light, air, and moisture, or more rapidly by the action of chlorine; but in the latter case it does not answer for the manufacture of candles, which is one of its principal applications. Wax candles are made by suspending the wicks upon a hoop over the cauldron of melted wax, which

is successively poured over them from a ladle till they have acquired the proper size, so that the candle consists of a series of layers of wax; the upper end is then shaped, and the lower cut off. Bleached or white wax is generally adulterated with more or less spermaceti, and sold at different prices accordingly; in this case it has not the peculiar lustre of pure wax, and is softer and more fusible. It is also largely adulterated with stearin or stearic acid, which is detected by the odour of fat or tallow which it evolves when highly heated, and by its crumbly texture; it may also be separated to a certain extent by ether or alcohol. Wax is insoluble in water, and scarcely acted upon by the acids, so that it forms a good lute or cement: boiling alcohol and ether partially dissolve it, and deposit the portion which they had dissolved on cooling. According to Brodie (*Phil. Trans.* 1847–49), bees' wax contains three substances separable by boiling alcohol, viz. *myricin* ($C_{92}H_{92}O_4$), which is insoluble; *cerin* ($C_{54}H_{54}O_4$), which is deposited in crystals as the solution cools; and *cerolein*, which is retained in solution. Their relative proportions vary, but in ordinary bees' wax there appears to be about 73 per cent. of myricin, 22 of cerin, and 5 of cerolein. [APIS; HIVES, BEE.]

Wax Opal. An inferior kind of Common Opal.

Wax-modelling. Wax is a substance formerly much used by sculptors in forming their models, and still greatly used by silversmiths. The founder's wax was commonly mixed with a little tallow, turpentine, and pitch, the quantity of wax being about ten to one of each of the other ingredients. Wax was especially used for hollow casting: when the safe-mould from the model was completed, it was filled in to a certain thickness with wax, and fixed, properly supported, in its place; the remaining cavity was then filled from the top with a fire-proof composition of plaster and brick-dust, to form a *core*. The mould was now removed, and a complete wax model showed itself; this the sculptor carefully revised, and again covered with a fire-proof mould of plaster, brick-dust, cowhair, and horsedung, put on with a brush in various layers; when it had reached a sufficient thickness, and was properly supported, a coal fire was kindled round it, and vents being prepared, every particle of wax was burnt out of it—a very anxious and tedious process. The whole was then bricked up and the pit filled with sand; the molten metal then took the place of the wax, and the cast was accomplished. Clay and sand modelling has now generally superseded this old wax method. A very simple mode of taking a wax cast is, to invert the mould in cold water, thus giving it a cold damp surface which instantly chills the molten wax poured into it at the points of contact, while the main bulk, remaining in a liquid state, will run out again as soon as the mould is turned over, giving the desired wax shell. This shell must then be filled in with a core, and proceeded with as above.

Another kind of wax modelling is the so-called *ceroplastic* art, i.e. modelling and casting in wax itself, not merely using the wax as a means of producing casts in other substances. To this class belong wax images; wax fruit and flowers, together with the wax anatomical and pathological models, now much in vogue, and of which many extraordinary examples exist in Florence, Paris, and London. Nearly all these wax models are cast from moulds; the mould may be in plaster of Paris, or a composition of bees' wax, Burgundy pitch, and Venice turpentine, with a very little olive oil. This composition has the great advantage of being *elastic*, and when thin can be peeled off the cast.

Wax images also are made by casting, but a cheap method is to mould the face in paper pulp and size, paint this mask in strong local colours, and then cover with two or three coats of fine wax: the colours will show through the wax, and the mask will require only the eyes and hair to be added; local effects can be modified by painting with wax and turpentine. (Wornum 'On Wax-modelling' in the Supplement to the *Penny Cyclopædia*.)

Way (A.-Sax. weg). The Sea term for progress. A ship in progress is said to have *way* upon her; when stationary, to have no *way*. Steering power is proportionate to *way*.

Ways and Means. When the House of Commons goes into committee of the whole house for the purpose of considering the manner in which funds are to be raised for the public expenditure, it is said to go into committee of ways and means.

Wayfaring-tree. A common name for *Viburnum Lantana*.

Wealden Formation. The name given in Geology to certain deposits occurring in England in the Weald or Wolds (wooded portions) of Kent, and hence to other contemporaneous rocks elsewhere. The Wealden deposits occur between the oolitic and cretaceous series. They are in England almost entirely of fresh-water origin, and include clays, sandstones, and limestones. The following is the series:—

1. *Weald Clay* of Surrey, Kent, and Sussex, with *Cypris*. Fresh water.
2. *Hastings Sands*. Tunbridge and Ashburton beds, separated by the Wadhurst clay and Ashdown sands, containing calc grit. Notwithstanding the name, the argillaceous element preponderates over the sand in this division as well as the other.
3. *Purbeck beds*. The Wealden beds have been traced for about 200 miles from east to west, and about the same distance from north-west to south-east. They probably represent a large delta, not, however, larger than many existing river deltas.

In English Geology it is always usual to treat this formation as distinct and interpolated. Its representatives in time certainly connect themselves either with the overlying or under-

lying marine formations of other countries, though it is not always possible to say with which.

The Wealden series in the typical Wealden district of England consists of the deposits called HASTINGS SANDS, which repose on the PURBECK STRATA. The uppermost member is the WEALD CLAY, a well-defined argillaceous band, loaded with minute cases of the bivalve crustaceans, and reaching round between the chalk and the Hastings sands. Between the sands and the clays, however, are sandstones and shelly limestones, the latter of which include a bed capable of taking a polish, and known as the *Sussex marble*. This bed is very characteristic. Among the limestones are valuable ironstones.

The Wealden series has always been regarded as the accumulations made at the mouth of a considerable river coming in from the west. The deposits extend, but are very poorly exhibited, across the Channel on the coast of France near Boulogne; and beds distinctly contemporaneous are found in Scotland, Westphalia, and Hanover. The latter are important from their magnitude and thickness. They consist of sandstones.

The *denudation of the Weald*, or the laying bare of the tract in which these river deposits are present, is a remarkable and interesting geological phenomenon. [VALLEY OF ELEVATION.] The chalk has once covered the whole of the Wealden deposits, has been lifted up and fractured along a line apparently nearly parallel to that of the course of the ancient river, and then washed away for a space on each side of the fracture. It now forms two escarpments facing each other, with the Hastings sand occupying the intervening valley. The Hastings sand, much lower in geological position, is higher in some places than the general level of the top of the chalk hills on each side. The time occupied in the elevation was probably very great; and the work of carrying away the disturbed rock was likewise spread over a very long period, and was exceedingly gradual.

The Wealden beds are interesting as containing the remains of gigantic herbivorous land reptiles, and also of the flying reptiles of the oolite, lias, and chalk.

Wealth (from *weal*; A.-Sax. welga, *rich*). In Political Economy, this term denotes such objects and services as are in demand in any community, and which are the products of labour. Natural qualities, as unworked mines or unappropriated forces, are not wealth, except metaphorically. Nor is labour wealth, except it be called effectively into activity by demand. But all products which can be measured by some standard of value are wealth, whether they be material objects, or that kind of labour which either directly or indirectly contributes to the production of objects in demand. Most economists, while they readily acknowledge the claim of material objects to the name of wealth, ignore or deny the right of labour to the title, though they sometimes admit that mechanical labour is part of public wealth. But it is difficult to see how manual labour can be called wealth, and mental labour be treated differently. Of course by labour is meant the concrete notion, i.e. the persons of those who proffer services. Money is wealth only in so far as it is the requisite machinery of commerce. Hence those communities which are best informed of the nature of money seek to diminish the amount of money which they employ to the least possible amount consistent with the convenience of exchange. The theory that money is wealth per se, was the enduring fallacy of past times. Nor again, when the aggregate of national wealth is estimated, must the rent of the natural powers of the soil and public debts be treated as wealth. They are both deductions from wealth, the former being consequent on the pressure of population, the latter being a mortgage on the future productiveness of the community.' Some, however, who have attempted to reckon the amount of national wealth, have carelessly included these elements.

National wealth is not a quantity, but a ratio. In the middle ages, Genoa and Venice were esteemed wealthy, and were really so. But it is probable that even taking into account the different value of money, the imports and exports of either of these cities did not equal those of a third-rate British port at the present time. Again, the phenomena of wealth may dazzle the eyes of those who consider a social state superficially, while the reality is something quite different. For ages the estimate of the riches of Hindustan was exaggerated by the wealth of a few potentates. Later experience has shown that the country is really very poor, for although it contains so many millions of inhabitants as to be nearly ten times as populous as England, the possible revenue which may be extracted from the people is comparatively small; while the capital which may be engaged in industrial pursuits needs, even for the most manifest public advantages, the aid of British savings.

Nations do not become wealthy by isolation, nor is the prosperity of a neighbouring country any weakness to another. On the contrary, the growth of foreign wealth is an indirect aid to the developement of prosperity at home. The delusion that one nation's gain is another's loss has been the fruitful cause of international jealousy and destructive wars. [POLITICAL ECONOMY.]

Again, the distribution of wealth is as important an object for economical consideration, as its production; for those nations only are permanently prosperous, in which facilities are given for the free developement of wealth among all members of the community. [CAPITAL; DISTRIBUTION; PROFIT.]

Wear or **Weir** (A.-Sax. wer). A dam in a river, sometimes formed by driving in rows of piles and weaving branches between them, filling up the interstices between the rows with stones.

WEAR. To put a ship on the other tack, by bringing her round with her stern to the wind. [VEER.]

Weather (A.-Sax. weder, Ger. wetter). The state or condition of the atmosphere, with respect to heat, cold, dryness, moisture, wind, rain, snow, fogs, &c. The various causes which determine the state of the atmosphere, and produce those changes which are incessantly taking place in its condition, and which are popularly called the *weather*, form the subjects of METEOROLOGY and CLIMATE. [ATMOSPHERE; BAROMETER; CLOUD; DEW; HAIL; HYGROMETRY; RAIN; WIND, &c.]

In all ages of the world, mankind have attempted to explain and prognosticate the changes of the weather; but such is the complication of the subject, and so great the multitude of circumstances to be taken into account, that no theory can furnish rules for determining the order in which they succeed each other, or for predicting the state of the weather at a distant future time with any approach to certainty. Nevertheless, all the different modifications of the atmosphere are the necessary results of principles, not only fixed and unalterable in their nature, but (many of them at least) well known in their separate and individual operation. The difficulty of tracing the results of their combined influences arises chiefly from their complexity and endless concatenation.

The principal cause of all the variations which take place in the state of the atmosphere is the heating action of the sun's rays; but in order to appreciate correctly the effect of this action, we must know not only the extent of the atmosphere, but the properties of all the substances of which it is composed. Modern science has discovered that the atmosphere is composed of three different gaseous fluids, everywhere combined in the same proportions, and penetrated by an ever-varying quantity of elastic vapour. These two distinct envelopes of air and vapour mechanically mixed have different relations to heat; and therefore, in consequence of the unequal temperature of the surface of the earth with which they are in contact, they cannot both be in a state of equilibrium at the same time. Owing to the diurnal rotation, the different parts of the atmosphere are constantly receiving different quantities of heat, as the solar rays penetrate more or less obliquely. This inequality of temperature produces wind, which, if the surface of the earth were perfectly regular and homogeneous, would always blow in the same direction; but as the surface of the earth is composed of materials of various kinds, and irregularly disposed, the distribution of heat over it is extremely irregular. The winds, sweeping along the surface, acquire its temperature; and hence the atmosphere also becomes irregularly heated. This produces an accumulation of air at one place, and a deficiency at another; and hence a subsequent rush to restore the equilibrium. As the air is cooled, it becomes also incapable of holding the same quantity of aqueous vapour, a portion of which is therefore set free, and gives rise to clouds, mist, rain, dew, snow, &c. Besides all this, we have to consider the developement of electricity; the disturbance of the atmosphere produced by the rise and fall of the tides; and there may then remain probably many other circumstances with which we are entirely unacquainted. This very imperfect enumeration may serve to give an idea of the difficulties to be overcome in forming a theory of the weather. [CLIMATE.]

It has always been a favourite prejudice that the weather is influenced in some mysterious manner by the moon. The moon can be supposed to act on the earth only in one of three ways; viz. by the solar rays which it reflects; by its attraction; or by an emanation of some unknown kind. Now, the light of the moon does not amount to $\frac{1}{100000}$ that of the sun; and the heat which it excites is so small as to be altogether inappreciable by the most delicate instruments, or the best devised experiments. With regard to the attraction of the moon, we see its influence on the tides of the ocean, and might therefore be disposed to allow it a similar influence on the atmosphere; but when we take into account the small specific gravity of atmospheric air in comparison with water, and the consequent smallness of the mass of matter to be acted upon, it will readily be perceived that this influence also must be extremely feeble. In fact, it has been demonstrated by Laplace, that the joint action of the solar and lunar attraction is incapable of producing more than an atmospheric tide flowing westward at the rate of about four miles a day, and this is scarcely, if at all, appreciable. As to the remaining supposition, that the moon may act on the atmosphere by some obscure emanation, it is sufficient to remark that no meteorological observations that have yet been made afford the slightest traces of any such connection between the earth and its satellite. The registers which are now kept in various observatories and other places also prove, contrary to the popular belief, that the changes of weather are in no way whatever dependent on the lunar phases. (*Annuaire du Bureau des Longitudes* for 1833; Kämptz, *Lehrbuch der Meteorologie*, and Walker's *Translation*; Schubler, *Einfluss des Mondes auf die Veränderung unserer Atmosphare*, Leipzig 1830; *Greenwich Meteor. Obs.*)

WEATHER. The Sea term for that side on which the wind blows. *To weather* is to pass to windward of an object.

Weather Boarding. In Architecture, feather-edged boarding nailed upright, the boards lapping over each other.

Weather Gage. A ship to windward of another is said to have the weather gage of her.

Weather Glass. A name commonly given to the BAROMETER; but sometimes also applied to other instruments for ascertaining the state of the atmosphere, or measuring atmospheric changes. It is thus applied to the various forms of the HYGROMETER.

Weathering of Rocks. The destruction and change of form produced on rocks by the

action of the weather All rocks are subject to this, and in some countries the effects are much greater than in others. Limestones are thus rendered highly picturesque, for they are acted on by the water in two ways, mechanical and chemical, the water dissolving out the limestone and undermining it; so that falls are frequent. The direct action on many kinds of sandstone is very great, as here also the water penetrates crevices and undermines the rock. On clays the result is yet more considerable.

Granite among the crystalline rocks shows remarkable instances of weathering in most countries. The *tors* of the west of England are some of them very good illustrations. One, called the *Cheesewring*, near Liskeard, consists of five blocks, of which the upper are larger than the lower, the whole pile being about fifteen feet high. The stones composing this and other similar piles suffer by the action of the weather most rapidly upon their edges and angles, which gradually become rounded, and the blocks then begin to totter and ultimately to fall. This tendency of square blocks to become spheroidal, which has sometimes been mistaken for the effect of friction, shows that attrition and transportation by streams are not always essential to their rounded appearance. The celebrated *Logging-stone* well exhibits the tendency of this kind of granite to cuboidal separation.

Cheesewring.

Weavers or **Textoriae.** The name of a tribe of spiders including those which fabricate webs in order to entrap their prey.

Weaving (Ger. weberei; the word appears in the Greek ὑφή, Sansc. vap, *a web*). An operation by which threads are formed into cloth by a process resembling darning. The loom by which weaving is accomplished is merely an instrument which enables the darning to be performed with a smaller expenditure of time and labour than would otherwise be required. The species of loom at present used by the natives of India is probably its most primitive form. Yet with this rude instrument the most delicate fabrics are produced, and it is mainly by increasing the rapidity of production rather than by improving the quality of the product, that the present generation of weavers has been enabled to excel the ancients in this department of industry. The Indian loom consists substantially of two horizontal rollers of bamboo between which the threads called the warp are stretched. Each alternate thread is raised by being attached by a loop to a vertical string which pulls it up, leaving a space between the layers through which a great wooden needle and thread, or *shuttle* as we call it, is projected, when the threads before raised are let down and the others raised, so that the same process of transmitting the shuttle may be again repeated. In this way, the fabric of cloth is built or darned up, thread by thread, and it is wound up on one of the rollers as it is completed, while a corresponding length of threads is unwound from the other roller in readiness to be transformed into cloth in its turn. In modern looms, the parts are all accurately made of iron and wood, and are so constructed that the process of weaving may be carried on with great rapidity. Apparatus has also been introduced, in some cases of a very complicated character, to enable figures and colours of different kinds to be interwoven in the cloth. But the principle of all existing looms is substantially that of a darning machine.

In the Indian looms and in the old loom used in this country, the shuttle was thrown from one side of the web to the other. But, about 1740, the *fly shuttle* was introduced by John Kay, of Bury. By this contrivance the shuttle was driven from side to side of the web by means of a handle wrought by the weaver's right hand, while the left gave motion to a swinging frame. The *power* loom is driven by steam. The chief peculiarity of the *pneumatic* loom is that the shuttle is shot from side to side by a blast of compressed air. All reciprocating looms, however, are defective, and the want now to be supplied is to construct a circular or revolving loom, in which the shuttle, instead of being driven backward and forward, should be impelled onward continously. It appears probable that a new form of loom may be introduced, in which the operations of the sewing machine will be imitated instead of that of simple darning; and the practical introduction of circular weaving may be thus promoted. In the *stocking* loom circular weaving has been already largely introduced. In the Jacquard loom, a chain of perforated cards is made to pass over a drum, and the strings by which the threads of the warp are raised pass over a pulley or edge with a leaden weight of small diameter hanging at the bottom of each. These weights at each stroke of the loom are presented to each successive card, and some of them are intercepted by the card, while others pass through holes in the card, so that by the holes in the card the particular threads of the warp which are raised for the weft to pass through are determined. In this way, the nature of the figure on the cards determines the nature of the figure on the fabic. The Jacquard loom is a modification of the old Damascus loom, in which the fabrics called *damasks* were first manufactured, with this difference only, that in the Damascus loom the pattern was produced by the skill of the workman, and perforated cards were not employed.

Websterite. The native subsulphate of alumina; named in memory of Webster the geologist. It occurs in white or yellowish-white reniform masses and botryoidal concretions, in a layer of ochreous clay, in the cliffs at Newhaven on the coast of Sussex, and in potholes in the chalk near Hove in the same county.

Wedge (A.-Sax. wecg). In Geometry, a solid having five sides or faces, three of which are rectangles, and the remaining two consequently triangles, and parallel to each other; hence the wedge, considered as a geometrical figure, is a prism with a triangular base. Its content is therefore equal to the area of the triangular base multiplied into the distance between the parallel planes.

Wedge. In Mechanics, this term denotes one of the five simple engines or mechanical powers, used sometimes for raising bodies, but more frequently for dividing or splitting them. In the former case, if we suppose the wedge to be urged by pressure, the action of the wedge is precisely the same as that of the inclined plane; for in point of mechanical advantage it clearly makes no difference whether the wedge be pushed under the load, or the load be drawn over the plane. The power is therefore to the force to be overcome as the tangent of the angle of the penetrating sides to the radius, leaving the friction out of consideration: hence the thinner the wedge, the greater is its effect. But when the wedge, as is generally the case, is driven forward by percussion, its power cannot be estimated exactly. The percussive tremor excited by the blow destroys for an instant the friction at the sides, and augments prodigiously the penetrating effect. Besides, when the wedge is used in rending wood or other substances, the parts of the block are generally separated to a considerable distance before the edge of the wedge, as in the annexed figure; in which case

it further acts as a lever, the power being applied at the end of the block or acting part of the wedge, and the resistance being at the point where the fibres begin to separate.

All the various kinds of cutting and piercing tools, as axes, knives, scissors, chisels, nails, pins, awls, &c., are modifications of the wedge. The angle in these cases is more or less acute, according to the purpose to which it is applied. The mechanical advantage is increased by diminishing the angle of the wedge; but the strength of the tool is thereby also diminished. In tools for cutting wood the angle is generally about 30°; for iron it is from 50° to 60°; and for brass from 80° to 90°. In general, the softer the substance to be divided, the more acute may the wedge be constructed.

Wedge Gun. [Rifled Guns.]

Wednesday. The fourth day of the week, consecrated to Odin or Woden. The Romans called it dies Mercurii, whence the French Mercredi.

Week (A.-Sax. weoc). A period of seven days, of uncertain origin, but which has been used from time immemorial in Eastern countries. The week did not enter into the calendar of the Greeks, who divided the civil month into three periods of ten days each; and it was not introduced at Rome till after the reign of Theodosius. The use of weeks, according to some writers, was suggested by the phases of the moon, while others refer its origin to the seven planets known in ancient times, and thus explain the circumstance that the days of the week have been universally named after the planets, according to a particular order. [Calendar.]

Wehrlite. A massive variety of Lievrite from Szurzaskő in Hungary; named after the Austrian councillor Wehrle.

Weigh (A.-Sax. wægan, Lat. veho). To lift the anchor out of the ground.

Weight. In Algebra. [Resultant.]

Weight. In Commerce and Experimental Philosophy, the measure of the force by which any body, or a given portion of any substance, gravitates to the earth. The process by which this measure is obtained is called *weighing*; and when required, as in many philosophical experiments, to be performed with great accuracy, is a tedious and delicate operation. [Balance.]

The determination of weight, like that of extension, consists in the comparison of the thing to be measured with some conventional standard. But it is impossible to fix such a standard by written law or oral description; for it is impossible to communicate by words, and without reference to a sensible object, any adequate idea of a pound-weight, or foot-rule. Standards of linear measure, not accurately defined indeed, but having an average value sufficiently well known for the rude purposes of mankind in the early stages of society, were furnished by the different parts of the human body; hence the measures *foot*, *cubit*, *span*, *pace*, &c. [Measures.] But the method of comparing the weights of bodies does not suggest itself so readily to the mind as the comparison of linear dimension, and is not so easily accomplished. A balance is necessary, the construction of which requires some degree of mechanical knowledge. Hence the art of weighing, though of great antiquity (Goguet, *Origine des Lois*, &c.) was probably practised at a later period, and in a still less accurate manner, than that of measuring. There has also been a much greater variety of standards of weight, still less definite than those of measure, as will be readily conceived by considering the origin and import of such terms as *stone*, *load*, *last*, &c. The term *pound* (pondus) implies only weight indefinitely. The *grain*, as a standard of small weight, being taken from the grains or corns of wheat, was perhaps the only denomination of weight that would universally convey anything like a precise idea.

As there is a constant ratio between the volumes and weights of the same substances when placed in the same physical circumstances, it is obvious that standards of weight may be derived from those of measure. For example, a cubic foot or a cubic inch of distilled water, at the same temperature, and under the same atmospheric pressure, will always have the same weight. Advantage has been taken of this property of bodies to connect weights with

measures in the metrical systems that have been adopted in this and other countries.

English Weights.—It was declared by the Great Charter that the weights should be the same all over England, but no ordinance, perhaps, was ever so ill observed; for the diversity that has prevailed, and which is still far from being remedied, has been so great as not only to produce confusion and inconvenience, but to render the system of weights adopted in one part of the country scarcely intelligible in another. The old English pound, which is said to have been the legal standard of weight from the time of William the Conqueror to that of Henry VII., was derived from the weight of grains of wheat: 32 grains gathered from the middle of the ear and well dried made a pennyweight, 20 pennyweights an ounce, and 12 ounces a pound. Henry VII. altered this weight, and introduced the *troy* pound instead, which was $\frac{1}{15}$ (or $\frac{3}{4}$ of an ounce) heavier than the old English pound. The troy pound was divided in the same manner as the old English pound, into ounces, pennyweights, and grains; but the pennyweight contained only 24 grains, and consequently a grain troy became a much heavier weight than the grain of wheat. In fact, the pound troy contains 5,760 grains, while the Saxon pound, which was divided into 7,680 grains, contained only 5,400 troy grains. Another weight, the *avoirdupois* pound, was introduced by a statute of 24 Henry VIII.; and though its first object was that of weighing butchers' meat in the market, it has gradually come to be used for all kinds of coarse goods or merchandise. Two legal measures of weight were thus established, and have continued to be used in the country ever since; the avoirdupois weight being used for common purposes, and the troy for the precious metals, and, with a different division, by apothecaries in compounding their drugs. The standard of these measures was at length definitely fixed by the Act of Parliament 5 Geo. IV. c. 74, entitled 'An Act for ascertaining and establishing Uniformity of Weights and Measures,' which has been amended by several subsequent statutes. The following are the terms in which the standard is defined by the Act: 'That from and after the first day of May, 1825, the standard brass weight of one pound troy weight made in the year 1758, now in the custody of the clerk of the House of Commons, shall be, and the same is hereby declared to be, the original and genuine standard measure of weight; and that such brass weight shall be, and is hereby denominated, the imperial standard troy pound; and shall be, and the same is hereby declared to be, the unit or only standard measure of weight, from which all all other weights shall be derived, computed, and ascertained; and that $\frac{1}{12}$ part of the said troy pound shall be an ounce, and that $\frac{1}{20}$ part of such ounce shall be a pennyweight, and $\frac{1}{24}$ part of such pennyweight shall be a grain, so that 5,760 such grains shall be a troy pound; and that 7,000 such grains shall be, and they are hereby declared to be, a pound avoirdupois, and that $\frac{1}{16}$ part of the said pound avoirdupois shall be an ounce avoirdupois, and that $\frac{1}{16}$ part of such ounce shall be a dram.'

It follows from this that the weight of the pound troy to that of the pound avoirdupois, or common pound, is in the proportion of 5,760 to 7,000, or of 144 to 175. The use of two different systems of weights was retained in compliance with the common usages of the country; and the motives which influenced the commissioners of weights and measures in recommending the system which has been adopted were thus explained by Mr. Davies Gilbert: 'The troy pound appeared to us to be the ancient weight of this kingdom, having, as we have reason to suppose, existed in the same state in the time of Edward the Confessor; and there are reasons, moreover, to believe that the word *troy* has no reference to any town in France, but rather to the monkish name given to London, of Troy Novant, founded on the legend of Brute. Troy weight, therefore, according to this etymology, is, in fact, London weight. We were induced, moreover, to preserve the troy weight, because all the coinage has uniformly been regulated by it; and all medical prescriptions and formulæ now are, and always have been, estimated by troy weight, under a peculiar subdivision which the College of Physicians have expressed themselves most anxious to preserve.'

In the sixth clause of the Act it is enacted, that if the standard troy pound should be lost or destroyed, it is to be restored by a reference to a cubic inch of distilled water, which has been found and is declared to be 252·458 troy grains, at the temperature of 62° of Fahrenheit, the barometer being at 30 inches. Hence the weight of a pennyweight troy is to that of a cubic inch of distilled water, in such circumstances, in the proportion of 24 to 252·458, or of 24,000 to 252,458; so that the weight of the cubic inch of distilled water must be conceived to be divided into 252,458 equal parts, and 24,000 of such parts will be the standard pennyweight; or 240 of such pennyweights will be the standard pound. The Acts 4 & 5 Wm. IV. c. 49, and 5 & 6 Wm. IV. c. 63, made no alteration in the method of recovering the standard.

In 1843, a committee consisting of several eminent authorities was appointed. Their report, signed by all the surviving members, was published in 1854. The committee determined to take the avoirdupois pound of 7,000 grains as a standard, and to construct the troy pound from it. They took the brass troy pounds in the possession of the Exchequer, and certain *platinum* pounds in the possession of the Royal Society and others. The former were found to have gained in weight by oxidation, and the platinum pounds only were used. From them a platinum pound was prepared weighing in vacuo 6,999·99845 grains. The form of the weight is a cylinder, with a groove surrounding it a little above the middle of its height for the

insertion of the ivory fork used in lifting it. The weight is enclosed in a mahogany box, the parts of which when screwed together cause the weight to be immovable. This box is enclosed in another box, and with the standard yard in a third box, and finally in a stone case in the vaulted stone room of the Exchequer. The proceedings of the committee received the sanction of the legislature by 18 & 19 Vict. c. 72.

For philosophical purposes and in delicate weighing, troy weight only is used, and the weight is usually reckoned in grains. By this means fractional numbers are avoided, and no ambiguity can arise, as there are no other grains than troy grains. Dr. Kelly, in his *Universal Cambist*, an elaborate and useful work, states that the dram avoirdupois, like the drachm of the apothecaries, has sometimes been divided into 3 scruples and 60 grains; but as no such weight as an avoirdupois grain ever existed, the use of the expression is an instance of the confusion inseparable from having different systems of weights, in which the same names are applied to things totally distinct.

The standards in the Exchequer are: those of weight; 16 avoirdupois weights, ranging from 56 lbs. to $\frac{1}{2}$ dram; 15 troy weights, under 5 Geo. IV. c. 74, from 1 lb. to 1 grain; 30 bullion troy weights, under 16 Vict. c. 29, from 500 oz. to ·001 oz.; those from ·001 oz. to ·005 oz. being of platinum wire, the others of brass, electro-gilt; a yard made of gun metal; ten measures of capacity, from the bushel to the half-gill; and two gas standards, one of weight, i.e. 62,321 lbs., the weight of a cubic foot of distilled water at 62° Fahrenheit; a cubic foot bottle; a 10-feet, 5-feet, and 1-foot gasholder. For a full account of the various proceedings for fixing and verifying the British standards, see Mr. Chisholm's *Report on the Exchequer Standards of Weight and Measure.*

Tables of British Weights.

1. *Imperial Troy Weight.*—Standard: One cubic inch of distilled water, at 62° Fahrenheit's thermometer, the barometer being 30 inches, weighs 252·458 troy grains.

grs.	dwts.	oz.	lb.
24 =	1	—	—
480 =	20 =	1	—
5760 =	240 =	12 =	1

Troy weight is used in weighing gold, silver, jewels, &c., and in philosophical experiments.

2. *Apothecaries' Weight.*—Standard: The same as in troy weight, with the ounce divided into 8 drachms and 24 scruples.

grs.	scrs. (℈)	drs. (ʒ)	oz. (℥)	lb. (℔)
20 =	1	—	—	—
60 =	3 =	1	—	—
480 =	24 =	8 =	1	—
5760 =	288 =	96 =	12 =	1

Medicines are compounded by this weight; but drugs are usually bought and sold by avoirdupois weight.

3. *Imperial Avoirdupois Weight.*—Standard: The same as in troy weight; and one avoirdupois pound = 7,000 troy grains.

drs.	oz.	lbs.	qrs.	cwts.	ton.
16 =	1	—	—	—	—
256 =	16 =	1	—	—	—
7,168 =	448 =	28 =	1	—	—
28,672 =	1,792 =	112 =	4 =	1	—
573,440 =	35,840 =	2,240 =	80 =	20 =	1

This weight is used for the general purposes of commerce.

The preceding are the British statute weights; but numerous other discordant denominations of weight, generally multiples of the avoirdupois pound, are still used in different parts of the country for weighing particular kinds of merchandise. One of the most common of these is the *stone*, which has a great variety of different significations. In London, however, only two stones are generally understood; viz. the stone of 8 pounds for butchers' meat, and the stone of 14 pounds for other commodities. (For values of different local weights, see Buchanan's *Tables of Weights and Measures*; General Paisley's work *On the Measures, Weights, and Money used in this Country*; M'Culloch's *Com. Dict.*; Kelly's *Universal Cambist*, &c.)

A particular denomination of weight, a *carat*, is used for weighing diamonds. An ounce troy is equivalent to $151\frac{1}{2}$ carats; whence a carat is nearly equal to $3\frac{1}{6}$ grains. In expressing the fineness of gold by *carats*, the term rather denotes a proportion than a weight. Thus gold 22 carats fine signifies an alloy such that the proportion of the weight of pure gold to that of the whole weight is as 22 to 24; or such that it contains 22 parts by weight of pure gold, and 2 parts of some inferior metal.

For the French system of weights, see Metric System.

Weight. In Mechanics, this term sometimes denotes the resistance to be overcome by a machine, whether in raising, or sustaining, or moving a heavy body. The force applied to the machine for this purpose is called the *moving power*; and when equilibrium subsists, the ratio of the weight to the moving power is termed the *mechanical advantage* of the machine. In all cases of equilibrium by the intervention of machinery, if the machine be put in motion by a small additional force, the space passed over by the moving power will be greater than that passed over by the weight, in proportion as the weight is greater than the moving power; or the product of the weight by its velocity will be equal to the product of the moving power by its velocity. [Momentum; Virtual Velocity.]

Weight (A.-Sax. wight). In Physics, that property of bodies in virtue of which they tend towards the centre of the earth. In this sense, *weight* is synonymous with *gravity*. [Gravity.]

Weight of Observations. [Probable Error.]

Weights and Scales. The use of these conveniences is very ancient, their earliest

employment being that of measuring money. Weights and scales were the instruments of the money changer in Greece and Rome. In Latin, to pay money is to weigh it; and in point of fact, all weights have been derived originally from the practice of weighing specie. The Sicilian pound, which has been adopted in all countries which have accepted the Roman system, and the German mark, which has prevailed in those which have been influenced by another system, are fundamental in all European weights, and have both been originally quantities of silver. Our own system of weights, while it accepted the pound, attempted to give precision to smaller quantities of money by referring them to a standard derived from the weight of sound average grains of corn. As payments by tale have superseded those by weight, the true origin of all weights has been overlooked.

The earliest scales were no doubt equal balances, the use of the steelyard (the auncel weight of our forefathers) being late both in the ancient and the modern world. But scales were possessed by all persons who were in the receipt of money, and formed a regular and necessary part of the establishment of all persons of any substance. There cannot, we think, be any doubt that at least to the time of Elizabeth payments were invariably made by weight. Statutes defining the standard, and insisting on uniformity in weights, were perpetually enacted, and the police of the old manorial courts [MANOR] was very effective in preserving the justness of weights used. The whole metrical system of England was derived from money weights. [MEASURES.]

The business of testing weights originally lay with the coroner (occasionally the justices in eyre), unless, as was frequently the case, it was reserved by special charter to local magistrates. At present the inspection of weights and the prosecution of offenders is in the hands of the local police of each town or district.

For ancient weights, see Hussey's *Essay*; for modern weights, Tate's *Modern Cambist*.

Weir. [WEAR.]

Weissigite. A mineral which occurs in the trap-rocks of Saxony and Scotland; in the latter country it is associated with zeolitic minerals, in the form of brick-red pseudomorphous crystals, at Calton Hill, Edinburgh, and massive and pseudomorphous near Old Kilpatrick in Dumbartonshire. The Scotch variety seems to be soda-felspar, or Albite; and the Saxon potash-felspar, or Orthoclase.

Weld. The *Reseda Luteola*, a plant cultivated for the use of the dyers. When the seeds are ripe, the plant is cut and dried. It yields a brownish yellow decoction, the colour of which is rendered paler by acids, and richer and deeper by alkalies. Alum throws down a yellow precipitate, and leaves the clear liquor of a fine lemon yellow; tartar also brightens its colour, and solutions of tin give it a dilute green tint. When a mixture of whiting and alum is added to a hot decoction of weld, a yellow precipitate is obtained, which, when collected, washed, and dried, is of a fine delicate colour, and much employed by paper-stainers. Weld is the *gaude* or *vaude* of the French dyers. Its peculiar colouring principle has been called *Luteoline*.

Welding. Some few metals are susceptible of being united by pressure or hammering, or of being *welded* together. Two pieces of potassium may be welded at common temperatures (from 60° to 80°); but the term is generally applied to the junction of two pieces of iron at a white heat, or of iron and steel. Platinum, also, may be welded at a white heat; and it is in this way that that valuable metal, when in the granular or pulverulent state, is worked into bars.

Well (A.-Sax.). In Architecture and Engineering, a deep pit sunk in the ground for collecting and retaining water, and built round with stone, brickwork, or other suitable material, to prevent the earth from falling in. Sometimes wells, after being excavated and built round, are filled in solid with masonry, so as to constitute great pillars or piles for important works to rest upon, and thus insure a good foundation. Such wells are very widely used in India; and part of St. Paul's Cathedral rests upon wells, where the ground was of doubtful solidity.

Before a well is dug, it should first be determined whether a mere reservoir be desired for the water which oozes out of the surface soil, or whether a perpetual spring is needed. If the former be the object in view, a depth of fifteen or twenty feet may probably suffice, though this cannot be expected to afford a constant supply for any large quantity of water, unless a watery vein or spring is hit on; in the latter case, 300 and 500 feet have in some instances been cut through before a permanent supply of water was found. Artesian wells are sometimes carried to a depth of nearly 2,000 feet. [ARTESIAN WELL.]

The art of well-digging is generally carried on by persons who devote themselves exclusively to this work. The site being fixed on, the ground-plan is a circle, generally of not more than six or eight feet in diameter; the digger then works down by means of a small short-handled spade, and a small implement of the pick-axe kind, the earthy materials being drawn up in buckets by the hand or a windlass fixed over the opening for the purpose.

There are two methods of building the stone or brick within the well, which is called the *steining*. In one of these a circular ring is formed, of the same diameter as the intended well, the timber of which it is composed being of the size of the brick-courses with which the well is to be lined. The lower edge of this circle is made sharp, and is shod with iron, so that it has a tendency to cut into the ground; this circular kerb is placed flat upon the ground, and the bricks are built upon it to a

considerable height, like a circular wall. The well-digger gets within this circle, and digs away the earth at the bottom; the weight of the wall then forces the kerb and the brick-work with which it is loaded to descend into the earth, and as fast as the earth is removed it sinks deeper, the circular brick wall being increased or raised at top as fast as it sinks down. Sometimes heavy temporary weights are placed on the top of the wall to force it into the ground; but when it gets very deep it will sink no longer, particularly if it passes through soft strata. In this case a second kerb of a smaller size is sometimes begun within the first. When a kerb will not sink from the softness of the strata, or when it is required to stop out water, the bricks or stones must be laid one by one at the bottom of the work, taking care that the work is not left unsupported in such a manner as to let the bricks fall as they are laid. The latter method is the one now generally pursued, except under peculiar circumstances. The steining is usually executed partly in dry and partly in cemented work laid in rings occurring in intervals of from five to fifteen feet; but sometimes it is necessary to execute the whole work in cement.

The steining of wells is sometimes formed of wrought or cast iron cylinders in about five-feet lengths joined by internal flanges, and guided, when being let down, by four battens fixed to the inside of the well. Sometimes the land-springs are shut out by such cylinders while the rest of the steining is formed in brick-work, and sometimes by 9-inch brickwork set in cement and puddled behind. The thickness proper for the brick steining varies with the nature of the soil and the diameter of the well. Large wells, or wells in soft soils, should have 9-inch steining in two separate 4½-inch rings laid in cement; but for small wells, or firm soils, one 4½-inch ring laid in cement will suffice, but the bricks should be hard and well burnt.

Well-diggers sometimes experience great difficulty from a noxious air which fills the well and suffocates them if they breathe it. The usual mode of clearing wells of such air, is by means of a large pair of bellows, and a long leathern pipe, which is hung down into the well to the bottom, and fresh air forced down by working the bellows.

To find the position of springs, when not deeply seated, the following indications will suffice: In the early part of the year, if the grass in any one spot assumes a lighter green than in others, or if in summer the gnats hover over a particular spot, or if in early morning more dense vapours rise from one spot than from others, water will be found beneath. Deeply seated springs can be discovered only by a careful examination of the geological formation. But the general rule will be found to hold good, that the subterranean waters flow in the same direction as the surface waters, though this rule is sometimes violated by accidental faults and dislocations in the strata. Springs are not often met with at the heads of valleys, but rather at the intersections of the subsidiary valleys with the principal one.

WELL. A small enclosed space near the mainmast, extending from the bottom of the ship to the principal gun deck, containing the pumps. It is fed by the limbers.

Wellingtonia. A fine coniferous tree from the mountains of California, supposed at one time to be distinct from SEQUOIA, to which it is now generally united.

Welwitschia (after Dr. Welwitsch, a German botanist). This is perhaps the most remarkable of all known plants. It comes from tropical Africa, where, along with other plants, it is called *Tumboa* by the natives. Dr. Hooker regards it as forming a genus of *Gnetaceæ*. In its youth its two original cotyledonary leaves appear to grow considerably, and extend horizontally in opposite directions, raised but little above the surface of the sand, whilst the intervening stock thickens and hardens, assuming an obconical shape, flat at the top, and rapidly tapering below into the descending root. As years go on, the original pair of leaves, having attained their full size and a hard tough fibrous consistence, do not die away, but gradually split up into shreds; the woody mass which bears them rises very little higher, but increases horizontally both above and below the insertion of the leaves, so as to clasp their base in a deep marginal slit or cavity; and from the upper side at the base of the leaf, several short flowering stalks are annually developed. These are erect, dichotomously branched jointed stems, rising from six inches to a foot in height, and bearing a pair of small opposite scales at each fork or joint, each branch being terminated by an oblong cone, under the scales of which are the flowers and seeds. The result is, that the country is studded with these misshapen table-like or anvil-like masses of wood, whose flat tops, pitted with the scars of old flowering-stems, never rise above a foot from the ground, but vary according to age in a horizontal diameter of from a few inches to five or six feet—those of about eighteen inches diameter being supposed to be already above a hundred years old.

Dr. Welwitsch found these misshapen monsters, deeply sunk in the soil with their middle sized roots, in considerable quantities at Cabro Negro (15° 40′ south lat.), on the dry plateau of the coast of Benguela, which is covered with loose sandy rough rubble, and is from 300 to 400 feet above the level of the sea. A little north of this place, at Mossamedes, in the neighbourhood of the Nicolas river, on the little Fishbay (at 14° 20′ south lat.), Herr Monteiro found it at a later period in a perfectly similar situation on quartzose schistose soil; and by Mr. Baines and Mr. Anderson it was seen in Damara-land, between 22° and 23° south latitude, in the neighbourhood of Whalefish Bay, in a district in which not a drop of rain ever falls. The distribution of this remarkable plant falls apparently between 14° and 23° south latitude. The -wn,

when divested of its leaves, resembles so closely the cracked surface of an old *Polyporus igniarius*, that it might, on a superficial view, be taken for a fungus.

In the *Transactions of the Linnean Society*, vol. xxiv., may be found a beautiful series of drawings of this remarkable plant.

Wen (A.-Sax. wenn). A term commonly applied to fleshy and other tumours, more especially when they affect the face or neck.

Wendish Language. A name given to the dialect belonging to the Wendic class of the Aryan family of languages spoken in Lusatia. The people who use it probably do not exceed 150,000 in number.

Werewolves. The first part of this word is the same as the *were* (Lat. vir, *a man*) in wergild. The phenomena and history of werewolves or lycanthropes have been examined by Mr. S. B. Gould in his *Book of Were-wolves*. Whether the idea may not be traced back to phrases of which the original meaning had been forgotten, is perhaps worth consideration. [Lycanthropy; Lycaon; Rishis, the Seven.]

Wergild (A.-Sax. from wer; Lat. vir, *a man*, and gild, Ger. geld, *gold*). Among the Anglo-Saxons, the compensation paid by a delinquent to the party injured, or his relations, for offences against the person. This custom was common to all the Teutonic tribes, and to many Celtic. It is mentioned by Tacitus in his account of the ancient Germans. The great distinction between Saxon freemen was that between the *eorls*, or nobility, and *ceorls*, or commonalty; and the *were* of the former was usually rated at six times the amount of that of the latter. [Thane.]

Wernerite. A name given to the mineral Scapolite, after Werner, the German mineralogist. It is a silicate of alumina, lime, and oxide of iron, found in Norway and Sweden, and also in Switzerland.

Wesleyans. [Methodists.]

Western Empire. The name given by historians to the western division of the Roman empire, when divided, by the will of Theodosius the Great, between his sons Honorius and Arcadius, A.D. 395. (Gibbon, *Roman Empire*; Milman, *Latin Christianity*; Bryce, *Holy Roman Empire*.)

Whale. [Balæna.]

Whale Fishery. In early times the whale was frequently found on the shores of this country, sometimes in large shoals, and was hunted partly for its oil, partly for the sake of food, whale meat, *balæna* or *baleine*, being frequently mentioned in ancient accounts as an article of purchase and sale. Greater refinement, and especially the progress of agriculture, which has enabled the community to supply itself with fresh meat *all the year through*, have superseded the use of whale as an article of food; and, for the last two centuries or more, this animal has been hunted only for its oil and a few other of its products, especially the laminated and fringed cartilages, which form a strainer for holding the minute insects on which the northern whale feeds.

The developement and sustentation of the whale fishery was for a long period a subject of great anxiety to the British parliament. It was believed to be an important source of wealth, and with greater reason it was imagined, that the fishery afforded an excellent school for rearing hardy seamen, available for the public service. To further the whale fishery, it was provided by law that bounties should be given to any ship, proportioned to its tonnage, which was engaged in this pursuit. In 75 years, between 1750 and 1820, the bounties paid to this industry amounted to 2,500,000*l.*, the average annual value of the produce being favourably estimated at 100,000*l.* It is easy to see that, even if the labour and capital employed in the fishery were taken to be worth nothing, the country lost a round annual sum by the process. In short, the industry was wholly factitious and absolutely unprofitable.

The delusion which occupied the minds of those who legislated for the support of the whale fishery was in great degree sustained by the notion, that all which can be got from the sea is gain; and the fact that, in such a case, the community is sufficiently alive to the contingency of such absolute profits without the aid of a bounty, was never recognised.

The whale fishery was twofold: that of the northern seas, in which the common whale was hunted; that of the southern, in which the chief object of pursuit was the spermaceti whale. The produce of both these animals, before chemistry had supplied the public with substitutes for train oil and spermaceti, was of far greater economical importance than it is now. But as the materials for artificial light and for the lubrication of machinery are now supplied from many other sources, it is probable that the fishery will be almost superseded as a regular branch of industry. In such a case whales will again become plentiful, just as the beaver, since the use of its fur as a material for hats has almost ceased, is becoming plentiful in places where it had been almost exterminated. For further details on the whale fishery, the reader is referred to the *Commercial Dictionary*.

Wheat (so called as being the white plant—Goth. hvaiteis; A.-Sax. hvæte; Lith. kwetys; all these words pointing to the Sansc. sveta, *white*: Max Müller, *Lectures on Language*, second series, ii.). The name of a well-known Cereal Grass, belonging to the genus *Triticum*, the cultivated forms of which have been produced, it is thought, by progressive developement from certain forms of *Ægilops*. [Triticum.]

Wheat is by far the most important and most extensively cultivated species of bread-corn raised in England. It is sown after fallow, turnips, cabbages, potatoes, beans, clover, and grasses, &c.; but it never, at least in the best farmed districts, follows any other white crop. Wheat may be raised on all sorts of

soils; but those of a clayey nature are the most suitable. So peculiarly, indeed, is wheat adapted to heavy stiff lands, that they are usually termed *wheat soils*. The lighter the soil, the less is it suited to this species of grain; and it is an error in practice to force the cultivation of wheat on soils, and under circumstances, better suited to the production of other grain. In this country it does not admit of being raised at a great elevation. As it is a crop on which the farmer mainly depends, the preparation for it, in whatever rotation it comes, should be an object of great care and attention. If it be intended to sow wheat after fallow, the land is repeatedly ploughed, harrowed, and well manured; if after clover, only one ploughing is given, and seldom more after beans; where tares have been previously sown, they are got off the land in sufficient time to plough it more than once; when wheat follows turnips or cabbages, it must, unless they be stored or eaten before winter, be sown in the spring months.

The varieties of Wheat are perpetually changing, in consequence of variations of culture, climate, and soil, those most in use being distinguished by different local terms. They may be divided into the two great classes of *red* and *white*—the latter being superior as respects quality of produce, and the former as respects productiveness and hardiness.

Winter wheat is seldom sown in any part of England before the beginning or middle of September, or later than the end of November. Spring wheat is generally sown between the middle of February and the middle of April. The seed is often pickled or steeped; a process intended to prevent *smut*. The quantity of seed allowed to an acre usually varies from 1 to 2½ bushels.

Wheat harvest generally begins in the south of England, early in August; in the midland counties it is about ten days, and in the northern counties from a fortnight to three weeks later. In the southern counties wheat is generally ready in a week or ten days after cutting; whereas in the north it is necessary to let it stand out for two or three weeks. In the southern, eastern, and midland counties, it is frequently put into barns: in the north, it is almost universally stacked.

As this grain is so extensively cultivated, frequently on very inferior soils, and after very imperfect preparation, the produce per acre varies materially in different counties and districts. It is also very liable to injury from bad seed time, a wet winter, or a blight during the period of its flowering (which last is the most common cause of the failure or deficiency of our wheat crops); so that its produce varies as much in different seasons on the same farms, and under the same management, as it does during the same season on different farms. The lowest quantity of produce, except where an absolute deficiency from blight occurs, may, perhaps, be rated at from 10 to 12 bushels an acre, and the highest at from 48 to 56 or 64 bushels. Occasionally, indeed, even more than this has been reaped on deep loams, and in some of the more favoured and highly cultivated parts of Kent, Essex, Lincoln, Somerset, &c.

The southern counties are the most distinguished for the quality as well as the quantity of their wheat. In the north, this grain is sometimes raised of a very fine quality; but generally it is inferior, being colder to the feel, darker coloured, thicker skinned, and yielding less flour. In the best wheat counties, and in good years, the weight of an imperial bushel of wheat varies from 62 to 64 lbs. Where the climate is naturally colder, wetter, and more backward, or in bad seasons, the weight of the bushel does not exceed 58 lbs. The weight of the straw is about double that of the grain; so that an acre yielding 30 bushels of wheat, at 60 lbs. per imperial bushel, would yield 3,600 lbs. of straw.

The geographical range over which wheat can be grown is peculiar. It is not produced in tropical climates. Here its place is taken by rice. There is a northern limit to its growth, beyond which oats can be cultivated. Here, however, wheat is not seen, only because there is not sufficient heat to ripen it. It is, on the whole, the hardiest of the cereals, and it is said that its quality is always best when it grows on that margin beyond which it will not ripen at all. In the same manner the vine has a wide geographical range, will grow luxuriantly where its fruit cannot come to maturity, will stand severe cold in winter, and produces better wine in such regions as approach its highest geographical limit.

Wheat is the most costly of the cereals. The seed sown on any given area is not more than half the amount which can be sown of other kinds of corn. The crop is scantier, and more exhausting to the soil. It sends its principal roots deeply into the earth. Hence it thrives well on strong and stiff ground, and can bear drought better than any other kind of grain. The whole, or nearly the whole, nutriment contained in the plant is lodged in the seed. Wheat straw, as fodder, is worth less than the straw of other grain, though it is very valuable for certain economical uses.

The meal or flour of wheat is better adapted to sustain the various vital functions than that of any other kind of grain. For many reasons, the employment of wheat as an article of food produces special economical effects on the community with which its use is customary. From the very earliest times wheat has been the common food of the people in this country. Rye, the closest analogue to wheat, has never been widely used in England; and barley, oats, and the leguminous plants have never been the staple food of any large section of the English nation. Five hundred years ago the English peasant ate wheaten bread, brewed his beer from barley malt, and gave oats to the horses. Fortunately he has never condescended to live on the meaner kinds of corn, and he owes much

his physical and economical position to this ıbit of life.

Up to the middle of the eighteenth century heat was grown in England in excess of the ants of the population. It is probable that ıe inhabitants of England and Wales did not ıen exceed 7,500,000. Since that time, howrer, the home growth of wheat has seldom ɜen sufficient for the wants of the increasing ɔpulation. Of course, with this increase, the ecessity of importing wheat increases also. he fact that there was an excess of production ɔncurrently with a growth of population, is to e explained by the great improvements in griculture which were effected in the country etween the Restoration and the accession of ɫeorge III. It was during this time that the ystem of turnip farming was established, and rtificial grasses were introduced.

At the present time, from one-third to oneɔurth of the wheat consumed in Great Britain nd Ireland is imported from foreign regions. ʼill within the last ten years, the chief supply f foreign wheat was shipped at the two ports, ɔantzic on the Baltic and Odessa on the ɜlack Sea. Latterly, however, vast quantities ıave been imported from the Western States of he American Union, the principal entrepôt f American grain being Chicago, which in the ourse of a few years has grown from a small nd unimportant village to a vast city. It eems reasonable to conclude that, as large tracts f prairie land are broken up and brought into ultivation, and as the great valleys of Upper ɔanada are brought within the influence of the orn trade, the supply of wheat will be even nore abundant, and suffice for the sustenance f the various populations of those parts of he Old World, in which trade and manufactures ıre flourishing.

ıccount of the Quantities of Foreign and Colonial Wheat imported into the United Kingdom, in each Year from 1850 *to* 1864 *inclusive, with the Annual Average Prices of Wheat per Imperial Quarter.*

Years	Imported	Annual Average Prices of Wheat per Imperial Quarter	
	Qrs.	s.	d.
1850	3,738,995	40	3
1851	3,812,008	38	6
1852	3,060,268	40	9
1853	4,915,430	53	3
1854	3,431,227	72	5
1855	2,667,702	74	8
1856	4,072,833	69	2
1857	3,437,957	56	4
1858	4,241,719	44	2
1859	4,000,922	43	9
1860	5,880,958	53	3
1861	6,912,815	55	4
1862	9,469,270	55	5
1863	7,489,000	50	4
1864	7,137,450	48	0

The proportionate money value of the three principal kinds of grain, wheat, barley, and oats, varies little even if remote periods are contrasted. Thus for the 140 years between 1261 and 1400, the proportion of barley to wheat (taken at 100) is 73·14, of oats 42·05. In our own time, or till lately, barley has been somewhat cheaper, perhaps by the operation of the malt duty, and other charges levied on grain and for distillation; oats are a little dearer, owing, probably, to the great increase in the number of horses kept for draught. Taking the same proportion, and estimating an average from the ten years ending 1865, wheat being as before at 100, barley will be 70, oats 45·95. Nor is there any doubt that if any similar decade of years were taken, the proportion would follow the same or nearly the same rates.

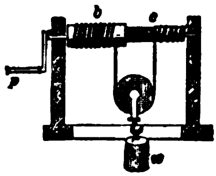
It must be borne in mind, that, in addition to the importation of wheat as grain, large quantities are annually imported as flour. Virtually the whole of the importation is retained for home consumption.

Wheel (A.-Sax. hweol). In a Ship, the wheel and axle by which the tiller is moved.

Wheel Animal or **Wheel Animalcule.** [ROTIFERS.]

Wheel and Axle. In Mechanics, one of the simple mechanical powers or machines, consisting of a wheel having a cylindrical axis passing through its centre, resting on pivots at its extremities, or supported in gudgeons, and capable of revolving. The power is applied to the circumference of the wheel, and the weight or force to be overcome to the circumference of the axle; equilibrium takes place when the power and weight are to each other inversely as the radii of the circles to which they are applied.

A form of the wheel and axle, called the *differential windlass*, is represented in the subjoined figure. The axle consists of two parts having different thicknesses; and the rope after being coiled round one of the parts is carried round a pulley attached to the weight, and coiled round the other in the opposite direction.



The power p is applied at the handle of the winch, which here takes the place of the wheel. In order to compute the advantage gained by this machine, let p denote the circumference described by the handle of the winch, b the circumference of the thicker part of the axle, and c that of the thinner part; then, while the winch makes one revolution in the direction which raises the weight, the part of the rope which passes from the one part of the axle to the other round the pulley will be shortened by the quantity $b-c$, and consequently the weight w will be raised through the height $\frac{1}{2}(b-c)$. But the space described in the same time by the power p is equal to that through which the

handle of the winch passes, or equal to a; therefore, by the principle of virtual velocities, $p : w :: \frac{1}{2} (b-c) : a$, or $p\,a = \frac{1}{2}\,w\,(b-c)$. As the circumferences of circles are to their radii in a constant ratio, it is evident that the formula will apply equally if the letters a, b, c be taken to represent the respective radii. In other words, the magnitude of the weight raised with any given force applied to the handle will be in the proportion of the slowness with which it is raised; and the more nearly the winding-up and the paying-out parts of the axle approximate in diameter, the slower will be the rate at which the weight is raised. The same principle is embodied in the contrivance termed *Hunter's screw*, and in all differential mechanisms.

Wheel Purchase. A simple contrivance for moving a wheeled carriage with increased power. It is formed by hooking a drag-rope to the tire of a wheel as near the ground as possible, carrying the running end up over the tire, and stretching it out so as to form a tangent to the wheel; when the rope is hauled on, the carriage advances. The power gained is in proportion to the diameter of the wheel.

Wheel Work. In Machinery, wheel work consists of a combination of wheels imparting motion to one another. The motion is communicated from the one wheel to the other, either by teeth cut in their circumferences, or on external surfaces, and working in one another, or by circular V grooves cut in the peripheries of the wheels, with corresponding circular projections for jamming tightly into the grooves—a combination usually known as *frictional gearing*. Pulleys driven by belts, though not commonly known as wheel work, come under the same general laws. In either of these ways the velocities of points in the circumferences of the impelled wheels are equal; and consequently their angular velocities, or the number of revolutions which they make in the same time, are inversely as their radii. When one wheel drives another by teeth, they necessarily turn in opposite directions; if united by a cord or belt, they will turn in the same direction, if the belt does not cross itself between the two wheels; but if the belt crosses itself, they will turn in opposite directions. The chief advantage of transmitting motion by cords or belts is, that the wheels may be placed at any convenient distance from each other, that they may be made to turn either in the same or in opposite directions, and that they may be driven at a higher rate of speed than would be suitable for toothed wheels.

When the resistance of the work is not great, wheels may be made to act on one another so as to communicate motion by the mere friction of their circumferences. In order to increase the friction, the surfaces of the rims are sometimes faced with buff leather, or wood cut against the grain, and pressed together with a certain degree of force. This method is sometimes used in spinning machinery, and has been applied successfully to the saw mill, and also to working cranes or hoists, but is seldom adopted in works on a great scale. Motion communicated in this manner proceeds smoothly and evenly, and is accompanied with little noise.

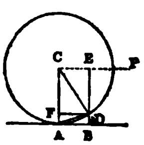
When motion is to be transmitted through a train of wheel work, toothed wheels are generally employed. A small wheel acted on by a large one is called a *pinion*, and the effect produced by any combination of wheel work is easily estimated by looking to the initial and final velocities. The number of revolutions made respectively by any engaged pair of wheels will vary as their circumferences, or, what is the same thing, as their diameters; if the diameter of a wheel, therefore, be ten times greater than that of a pinion engaged with it, then for every revolution made by the wheel, the pinion must make ten, or for every revolution made by the pinion the wheel must make $\frac{1}{10}$ of a revolution. Now, seeing that power is pressure multiplied by space, the less the space through which the axle passes, the greater must be the force with which it turns, and the greater the space the less the force. In winches and cranes, it is consequently easy to estimate the weight which will be raised by any given pressure applied to the handle, for we have only to ascertain the relative velocities of the handle and of the weight, and if the weight moves with only $\frac{1}{1000}$ of the speed of the handle, then the rotatory pressure applied to the handle will counteract 1,000 times the pressure at the other end of the machine, or raise 1,000 times the weight.

Toothed wheels, as distinguished by the position of the teeth relatively to the axis, are of three kinds: *spur wheels*, *crown wheels*, and *bevelled wheels*. When the teeth are raised upon the edge of the wheel, or are perpendicular to the axis, the wheel is a *spur wheel*; when they are raised parallel to the axis, or perpendicular to the plane of the wheel, it is a *crown wheel*; and when they are raised on a surface inclined to the plane of the wheel, it is called a *bevelled wheel*. The combination of a crown wheel with a spur wheel as pinion is used when motion is to be communicated round one axis to another at right angles to it. Two bevelled wheels are employed to transmit motion from one axis to another inclined to it at any proposed angle. Wheels moving in opposite directions with an intermediate wheel between them, which is capable of being carried round on a radial arm, are termed *differential wheels*. If the two wheels are made to perform the same number of revolutions per minute in opposite directions, but if one has a tooth more than the other, then at each revolution the intermediate wheel will be advanced a tooth, carrying the radial arm with it in slow revolution. Sometimes wheels are made elliptical, eccentric, and of other forms, for the purpose of imparting peculiar motions; and in the sun and planet wheels used in old varieties of the steam engine, one wheel was made to revolve round the other.

The proper mode of forming the teeth of wheels is described in a separate article. [TEETH

OF WHEELS.] In large wheels, and where a very smooth motion is necessary, the teeth of wheels are sometimes formed in steps, or the wheel is cut transversely into a number of thin and parallel wheels which are bolted together; but each succeeding wheel is set a little in arrear of the preceding one on the shaft, so that the teeth of the several wheels do not come in the same line with one another, but break bond. This expedient we owe to the ingenuity of Hooke, as we also owe to him the expedient of spiral gearing, by which the same end is attained. Sometimes an endless screw is made to work into teeth on the edge of a wheel, the wheel being thus advanced a tooth for each revolution made by the screw. In mill gearing, the teeth of the wheels are generally made too long, and thus more sliding friction is produced than would be the case if shorter teeth were employed. (Bourne *On the Steam Engine*.)

Wheels of Carriages. Wheels applied to carriages serve a twofold purpose. In the first place, they greatly diminish the friction on the ground by transferring it from the circumference to the nave and axle; and, in the second place, they serve to raise the carriage more easily over obstacles and asperities met with on the roads. The friction would be diminished in the proportion of the circumference of the axle to that of the wheel, even if the wheel could be well lubricated, and hence the larger the wheel, and the smaller the axle, the less is the friction. The mechanical advantage of the wheel in surmounting an obstacle may be computed from the principle of the lever. Let the wheel touch the horizontal line of traction in the point A, and meet a protuberance B D. Suppose the line of draft C P to be parallel to A B, join C D, and draw the perpendiculars D E and D F. We may suppose the power to be applied at E, and the weight at F, and the action is then the same as the bent lever E D F turning round the fulcrum at D. Hence P : W : : F D : D E. But F D : D E : : tan F C D : 1; and tan F C D = tan 2 (D A B); therefore P = W tan 2 (D A B). Now, it is obvious that the angle D A B increases as the radius of the circle diminishes; and therefore the weight W being constant, the power required to overcome an obstacle of a given height is diminished when the diameter is increased. Large wheels are therefore best adapted for surmounting inequalities of the road. There are, however, circumstances which prescribe limits to the height of the wheels of carriages. If the radius A C exceeds the height of that part of the horse to which the traces are attached, the line of traction C P will be inclined to the horizon, and part of the power will be exerted in pressing the wheel against the ground. The best average size of wheels is considered to be about 6 feet in diameter. The fore wheels of carriages and waggons are usually made much smaller than



this, to enable them to swivel beneath the floor of the vehicle.

Wheel-ore. A macled variety of Bournonite found at Herod's-foot Mine in Cornwall, and at Kapnik in Transylvania.

Whelps. Short upright pieces placed round the barrel of the capstan, to afford resting points for the messenger or hawsers.

Wherry (another form of FERRY). A boat with bow and stern nearly alike, and both making a very large angle with the keel.

Whetstone. A talcy slate containing silica, used for hones. [NOVACULITE.]

Whewellite. A native oxalate of lime from Hungary; named after Dr. Whewell, late master of Trinity College, Cambridge.

Whey (A.-Sax. hwæg). The limpid part of milk which remains after the separation of the curd and butter. It consists chiefly of water holding between three and four per cent. of sugar of milk in solution. [MILK.]

Whigs. The well-known designation of a political party in English history. It was first used in the reign of Charles II., the term being afterwards assumed as a party name by that body of politicians who were most active in placing William III. on the throne of England. Since that time it has been borne by successive generations of those who have followed in the same political line. Generally speaking, the principles of the Whigs have been popular, and their measures have tended to increase the democratic influence in the constitution. Defoe (*Memoirs of the Church of Scotland*, 1717, p. 173), speaking of the Covenanters, thus accounts for the origin of the name: 'This is the first time that the name of a Whigg was used in the world—I mean as applied to a man or to a party of men; and these were the original primitive Whiggs, the name for many years being given to no other people. The word is said to be taken from a mixed drink the poor men drank in their wanderings, composed of water and sour milk.' But Bishop Burnet, who lived nearer to the time in which the nickname was invented, gives the following explanation (*History of his Own Times*): 'The south-west counties of Scotland have seldom corn enough to serve them round the year, and the northern parts producing more than they need, those in the west come in the summer to buy at Leith the stores that come from the north; and from a word *whiggam*, used in driving their horses, all that drove were called Whiggamores, and, shorter, the Whiggs. Now, in that year, after the news came down of Duke Hamilton's defeat, the ministers animated their people to rise and march to Edinburgh, and they came up marching on the head of their parishes with an unheard-of fury, praying and preaching all the way as they came. The marquis of Argyle and his party came and headed them, they being about six thousand. This was called the Whiggamores' inroad, and ever after that all that opposed the court came, in contempt, to be called Whiggs; and from Scotland the word

was brought into England, where it is now one of our unhappy terms of distinction.'

Whin. [ULEX.]

Whinstone. A species of basaltic rock, or greenstone, forming hard dykes penetrating other rocks. The name is also sometimes locally applied to bedded rock of the same nature.

Whirlpool. A vortex, eddy, or gulf, where the water has a circular motion. Whirlpools are produced by the meeting of currents which run in different directions. Their danger to navigation is well known, but is perhaps not equal to the dread which sailors entertain of them. Some of the most celebrated are the Euripus, near the coast of Negropont; the Charybdis, in the straits of Sicily; and the Maelstrom, on the northern coast of Norway. The latter is now known to be of a very harmless character. (Murray's *Geography*, Introd.)

Whirlwind. A revolving column or mass of air, supposed with most probability to be produced by the meeting of two currents of air blowing in opposite directions. It is analogous to the *whirlpool*. When the opposite currents have the same velocity, the circulation will be maintained at the same spot; but if the motion of one of them is more rapid than that of the other, it will transport the whirling motion with its excess of celerity, and a progressive and rotatory motion are thus maintained at the same time. Whirlwinds generally occur in summer, and are most violent in tropical countries, where they frequently produce most destructive effects. The diminution of atmospheric pressure arising from the centrifugal force of the revolving column is thus computed by Professor Leslie: 'If r denote in feet the radius of the extreme circle described by the whirlwind, and t the time of circumvolution in seconds, the elasticity, or pressure of the column at the verge, will suffer a diminution corresponding to the fraction $\frac{5r}{4t^2}$. The amount of this diminution over the whole base would be reduced to three-fourths; and, consequently, h expressing the height of the revolving column of air, $\frac{15rh}{16t^2}$ would represent the mean effect of centrifugal action. Suppose the whirlwind to have an elevation of 200 feet, and a radius of 50, and to circulate in 3 seconds, the diminished pressure would be equal to the weight of a column of $\frac{15 \times 50 \times 200}{16 \times 9} = 1040$ feet. This example, assuming a celerity of sixty-five miles an hour, might be reckoned an extreme case; but it would occasion the mercury to sink in the barometer more than an inch, or 1·12.' (*Ency. Brit.* art. 'Meteorology.') [STORM; WINDS.]

Whisky (for the origin of the word, see USQUEBAUGH). A species of corn spirit, having the smoky flavour of burnt peat. [DISTILLATION.]

Whispering Domes or Galleries. Places in which whispers or feeble sounds are communicated to a greater distance than under any ordinary circumstances. The dome of St. Paul's church in London furnishes an instance. [SOUND.]

Whist (so called from whist, *be silent*, as requiring close attention). A game at cards, played by four persons, in a double combination, two of them being *partners* against a partnership of the other two. A full pack of fifty-two cards is used, and they rank in their natural order, except that the ace of each suit, instead of being the lowest, is made the highest. The cards are dealt round, thirteen to each player, the last or bottom one, belonging to the dealer, being *turned up* or shown; the suit to which this belongs is called the *trump* suit, and takes precedence of all the others.

The player to the left of the dealer then plays a card, to which the other players in succession must *follow suit*, i.e. play cards of the same suit, if they have them. These four cards constitute a *trick*, which is won by the person who plays the highest card, and is picked up by the winner or his partner. The winner of this then *leads*, or commences, a new trick, and so on till the whole thirteen are played.

When a player cannot follow suit, i.e. has no card of the suit led, he may either play a trump, which wins the trick by the precedence of the suit, or may *discard* a card of some other suit.

The score is made in two ways, by *tricks* and *honours*.

The partners who, together, gain the majority of tricks in the hand, score one for every trick made above six.

The ace, king, queen, and knave of the trump suit, are called *honours*, and score one each for whoever holds them. Thus, if one partnership hold two between them, the other partnership also holding two, they cancel each other, and no one scores. If one partnership hold three honours, and the other one, the former score the difference—two, and are said to count *two by honours*. If all four honours are in the hands of one partnership, they count *four by honours*.

The points thus scored by tricks and honours are called *game points*. In the old-fashioned or *long* whist, ten of these make a game; in the modern or *short* whist, the number has been reduced to five.

Two games, won by the same party, constitute a *rubber*, and the games have different values, depending on the state of the score of the losing party. These details, as well as other laws affecting the conduct of the game, may be found in books on the subject.

Although, as will be seen, the construction of the game is so exceedingly simple that a child may learn it in an hour, yet the option which each player has as to the card he shall play, leaves so much scope for voluntary action as to give whist an exceedingly high character in an intellectual point of view. A good player must, in the first place, be master of a somewhat re-

condite and elaborate *system* of play, which has been deduced by a long series of observations and reasonings as the best to be followed; he must then *observe* and *remember* very carefully the cards played, which furnish the data on which be proceeds; from these data he must next draw rapid *inferences*, as to the distribution in the various hands of the cards yet unseen; and finally he must act on the whole of the information thus gained, with judgment and skill, for which there is the widest possible scope. To do all this well requires not only very high mental and intellectual power, but considerable study and long practice. Hence this fine game has always commanded the attention of men of the first order of mind.

The origin of whist is somewhat obscure; but it has existed in its present form a long time. Hoyle appears to have been the first to perceive, a century and a quarter ago, that it was capable of being reduced to a scientific and logical system of high intellectual merit; and though his descriptions were somewhat obscure, they served to establish a well-marked school of play.

This has been adopted in its general form by all succeeding writers and players of eminence, whose experience and thought have gradually developed the system into a more complete and perfect form, and have added to it modern improvements of much interest and value, tending still further to raise the intellectual character of the game.

There are many books published which contain directions for the practice of whist-playing; but the clearest exposition of the theory on which the modern scientific system of play is based, will be found in an essay forming the second part of the sixteenth and following editions of *Short Whist*, by Major A.

It is shown in this essay that the basis of the true theory of the game lies in *combining* the hands of the two partners. It forbids the player to consider his own hand apart from that of his partner, but enjoins him to treat both in strict conjunction; teaching him, in fact, to play the *two hands combined*, as if they were one.

It is impossible here to explain this system more fully; but we may add a summary of the more important rules which characterise the modern scientific game.

1. Your first lead should *inform* your partner what is the most important component of your hand. Therefore it should be from your *best long suit*.

2. In this suit, having ace and king, lead king, then ace.

Having king and queen, lead king.

Having ace, queen, knave, lead ace, then queen.

Having ace and four small ones, lead ace, then smallest.

Having queen, knave, then lead queen.

In most other cases lead the lowest.

3. Lead your own suit before you return your partner's, unless he leads trumps, which return immediately.

4. In returning your partner's lead, if you hold not more than three cards of the suit originally, return the highest; if more, the lowest.

5. But, in any position, if you hold the master card, play it the second round.

6. When at a loss for a lead, lead up to the weak hand, or through the strong one.

7. Second hand, generally play your lowest, unless you hold ace and king, or king and queen, when put the lowest of them on.

8. Holding five or more trumps, always lead them the first opportunity, or signal to your partner to do so.

9. Look out for your partner's signal for trumps, to which, holding not more than three, lead out your highest; if more than three, your lowest.

10. Do not lead through an honour turned up, unless you otherwise wish trumps led.

11. Do not trump a doubtful trick second hand if you hold more than three trumps; with three or less, trump fearlessly.

12. Do not force your partner if you hold less than four trumps yourself.

13. But force a strong adverse trump-hand whenever you can.

14. Always play the lowest of a sequence, if not leading.

15. Discard from weak suits, not from strong ones.

White (A.-Sax. hwit, Ger. weiss, perhaps akin to Lat. videre, visus [WHEAT]). In Painting, a negative colour (if such definition may be allowed); the opposite is *black*, black being void of all colour, properly so called. White objects are assumed to reflect all the light that falls upon them, and black objects are supposed to absorb it all; coloured objects are such as partially absorb and partially reflect light.

WHITE. The colour produced by the combination of the complementary colours, yellow and blue, or crimson and green; and also, by all the prismatic colours mixed in the same proportions as they exist in the solar rays. This is proved both by decomposing white light by means of a prism, and by recompounding the primitive colours in due proportions. [COLOUR; LIGHT; REFRACTION.]

White Antimony-ore. Native oxide of antimony. [VALENTINITE.]

White Arsenic. Oxide of arsenic, or arsenious acid.

White Bait. The name of a small and peculiar species of *Clupea*; confounded, until studied by Mr. Yarrell, with the young of the shad (*Clupea alosa*). The young fish of the white bait (*Clupea alba*, Yarrell) ascend the Thames at the beginning of April, and continue in that part of the river where there is a mixture of salt with fresh water until September, when young fish of the year four or five inches long are not uncommon, though accompanied by others of smaller size; but the parent fish are believed not to ascend beyond

the estuary. The young of the shad are not two inches and a half long till November, when the white bait season is over; and they are distinguished by a spotted appearance behind the edge of the upper part of the operculum, which the white bait never exhibits.

White Caps. A name employed sometimes to indicate *Agaricus arvensis*, which is more commonly known as the Horse Mushroom.

White Cobalt-ore. Native arsenide of cobalt. [SMALTINE.]

White Copper. An alloy used by the Chinese, and called by them Packfong or Pakfong: it is composed, according to Dr. Fife, of 40·4 parts of copper, 25·4 of zinc, 31·6 of nickel, and 2·6 of iron. *German silver* is a modification of this alloy.

White Copper-ore. Native arsenide of copper. [DOMEYKITE.]

White Eagle, Order of the. An order of knighthood in Poland, instituted by Vladislas V. in 1325, and revived by Frederic Augustus I. in 1705.

White Flux. A metalluric reagent, chiefly composed of carbonate of potash.

White Fog. [HOLCUS.]

White Gunpowder. White gunpowder is made by powdering separately equal weights of chlorate of potash, white sugar, and ferrocyanide of potassium, and mixing them cautiously, as it may explode by percussion. It ignites if a drop of sulphuric acid, or a red-hot body, be brought into contact with it. Its explosive power is greater than that of ordinary gunpowder; but it is not available for guns, on account of the rapidity and violence of its combustion.

White Lead. Basic carbonate of lead. This important compound, of which from 17,000 to 20,000 tons are annually manufactured in England, is used chiefly as the basis of white oil paint: it is also employed, to a small extent, in the manufacture of cements. It is chiefly made in two ways: either by precipitation, as when carbonic acid or a carbonate is used to decompose a soluble salt, or a basic salt of lead; or by exposing plates of cast lead to the joint action of the vapour of acetic acid, air, and carbonic acid: it is by the latter process only that the resulting carbonate of lead is obtained of that degree of density and opacity, and perfect freedom from crystalline texture, which fits it for paint. This last, commonly called the *Dutch process*, was introduced into England about the year 1780. White lead is often largely adulterated with sulphate of baryta, which is detected by insolubility in dilute nitric acid, whereas pure white lead is entirely dissolved by it. [LEAD.]

White Lead-ore. Native carbonate of lead. [CERUSITE.]

White Leg. A disease which generally occurs in women soon after delivery, and which has been erroneously supposed to arise from redundancy of milk. It comes on with stiffness and pain of the limb, which afterwards becomes tumid and tense from the effusion of serum. The disease is essentially an inflammation of the femoral vein, followed by complete or partial plugging of the vessel by a coagulum of blood.

White Line. In Printing, a blank line across the page, formerly generally placed after a paragraph, but now used to mark a greater division of the subject there than that which is shown by the paragraph.

White Precipitate. The white powder which falls on adding ammonia to a solution of corrosive sublimate: it is a compound of peroxide and bichloride of mercury with ammonia: it is virulently poisonous, and is chiefly used in ointments and for killing vermin. It has been regarded as an *amido-chloride* of mercury, and represented as $Hg\ NH_2$, $Hg\ Cl$.

White Stone. A lapidary's name for limpid and colourless rock crystal when cut for jewellery.

White Tellurium. The name given to silver-white or slightly yellowish varieties of Sylvanite.

White Vitriol. The old name of sulphate of ZINC.

White Wood. One of the names applied to the timber of *Tilia americana*. It is also occasionally given to that of *Liriodendron tulipiferum*, *Oreodaphne Leucoxylon*, *Nectandra leucantha*, *Tecoma Leucoxylon*, *Tecoma pentaphylla*, *Lagunaria Patersoni*, and *Pittosporum bicolor*.

Whitefieldian Methodists. The name given to the most numerous body of the Methodists after the Wesleyans, so called from Whitefield, whose early connection with the METHODISTS will be found noticed under that term.

Whiting. The name of a species of the Cod tribe (*Merlangus vulgaris*, Cuv.), and the type of a subgenus, distinguished from the true cod by the absence of the barbules at the chin.

WHITING. Chalk, finely levigated by washing, and used for whitewash and distemper-painting, is sold under this name.

Whitlow (Sax.). A painful inflammation, tending to suppuration, at and about the ends of the fingers.

Whitneyite. A native arsenide of copper found on the north shore of Lake Superior, and named after Professor Whitney.

Whitsunday. In the Calendar, the seventh Sunday, or fiftieth day inclusive after Easter. *Whitsuntide* corresponds with *Pentecost*. This Sunday was called in the ancient church *Dominica Alba*, White Sunday; or *Dominica in Albis*, the Sunday in which *white garments were worn*, it having been formerly a custom with those who were baptised on this day to dress in white for the occasion. The term, however, has by some been derived from the Saxon *wlas*, octave, the eighth from Easter.

Whooping Cough. [HOOPING COUGH.]

Whortleberry (A.-Sax. heort-berg). The name of the *Vaccinium* genus, but especially applied in this country to the fruit of *Vaccinium Myrtillus*.

Wichtyne or **Wichtisite.** A mineral composed of silicate of alumina, with the silicates of iron, lime, soda, and magnesia, met with in black masses at Wichtis, in Finland.

Wickliffites. [LOLLARDS.]

Wildgrave (Ger. graf, *count*). A title assumed in the middle ages, like those of Raugrave and Rhingrave, by certain small dynasties of feudal chieftains in the neighbourhood of the Rhine. A branch of the family of Salm now claims this title.

Wilhelmite or **Willemite.** Native anhydrous silicate of zinc, named after Wilhelm I. king of the Netherlands. It is found crystallised, granular, and massive, at Vieille Montagne, near Aix-la-Chapelle. [WILLIAMSITE.]

Will or **Testament.** In Law, the legal declaration of a man's intentions as to what he wills to be performed after his death. In strictness of language, the term *will* is limited to land; *testament*, to personal estate.

Previously to the reign of Henry VIII. there was no general power of devising lands in England, though such a right existed in some exceptional instances. In that reign two statutes were passed (32 Hen. VIII. c. 1 and 34 & 35 Hen. VIII. c. 5) which authorised testators to devise their lands held in socage, and two third parts of their lands held by the then existing military tenure of knight's service; and the abolition of military tenures in 12 Ch. II., by converting all fee simple estates into socage tenure [TENURE], had the incidental effect of rendering them all devisable by will. The power of making a will over personal property existed from a much earlier period, although anciently a man could not dispose by will of more than one third part of his general personal property, if he left a wife *and* children, or of more than half if he left either wife *or* children. This ancient rule, however, gradually became subject to many exceptions by the effect of local customs, until the rule itself took the place of an exception, and became confined to such places as had a custom in its favour, and even in those places it was ultimately abolished by a series of statutes, the last of which was 11 Geo. I. c. 18. Ever since the passing of the Statute of Frauds (29 Ch. II. c. 3) it has been necessary that wills of real property should be in writing; but nuncupative or verbal wills of personal property were, previously to the year 1838, admitted under certain restrictions, which, however, were so stringent that such wills had become practically obsolete.

The Act of 1837 for the amendment of the laws with respect to wills (7 Wm. IV. and 1 Vict. c. 26) is now the governing statute as regards wills in England and Ireland. All wills (except those of seamen and soldiers on service), whether of real or personal property, must be in writing, and signed at the foot by the testator or some other person in his presence and by his direction; and such signature must be made and acknowledged by the testator in the presence of two or more witnesses present at the same time; and such witnesses must attest and subscribe the will in the presence of the testator. All appointments by will, whatever formalities may have been required by the creator of the power, must now be made according to the provisions of this statute, and require no further form. The same statute enacts that no will of a minor shall be valid. All devises and gifts by will to an attesting witness, or to the husband or wife of an attesting witness, are void. Wills can now be revoked only by the marriage of the testator, or by another will duly executed, or some writing declaring an intention to revoke, and executed in the same manner as a disposing will, or by burning, tearing, or otherwise destroying by, *or* in the presence and by the direction of, the testator, with intention to revoke. All wills now speak (with reference to the property comprised in them) from the death of the testator, unless they show on the face a contrary intention, i. e. the will acts upon the property which he possesses at his death.

A married woman cannot make a will of lands or tenements; nor, without the consent of her husband, of personalty, unless in either case she is authorised to do so by some special power of appointment.

A disposition by will of real property is termed a *devise*; of personal property, a *bequest* or *legacy*. The death of a devisee or legatee in the lifetime of the testator has in most cases the effect of causing the devise or legacy to *lapse* or fail.

In the construction of wills the courts have, from a wish to carry out the intention of testators, deviated in some few respects from the technical rules applicable to other dispositions of property. The effect of this has been, however, to create a most erroneous impression, less general perhaps now than formerly, that any testamentary disposition, however informal, may be relied upon to carry out the real intention of its framer, although such intention be expressed in careless or inaccurate language, or even left to be inferred from a presumed knowledge of the testator's family or circumstances. So far, however, is this from being the case, that it may be confidently stated that there are no documents so difficult to prepare as wills, none which require more care or deliberation, none whose construction is so frequently the subject of litigation. Every testator who wishes to feel reasonably sure that his intentions will actually be carried out, should be careful, in the first place, to frame his proposed testamentary dispositions in a manner as simple and free from complication as the circumstances of his family will admit of; and, secondly, to have those dispositions put into formal shape under able and deliberate professional advice.

In Scotland, the right of bequest, strictly so called, is confined to personal property, although real or heritable property, which includes many securities for money, and other

particulars ranked in England with personal property, may be disposed of by a deed of settlement of a testamentary nature, executed with certain formalities.

According to French (and, in general, civil) law, a will may be either *holograph*, i. e. written as well as signed by the testator; *public*, i. e. *received* by a notary in the presence of four witnesses (or two notaries with two witnesses); *mystic*, i. e. secret, which may be presented, sealed, to a notary in the presence of six witnesses. In France, however, a testator cannot dispose by will of more than the quotité disponible of his property, viz. half if he leaves one child, a third if he leaves two children, a fourth if he leaves three or more children; and the testamentary power is subject to many other restrictions. There is, indeed, probably no legal system under which testators enjoy a more unfettered power of disposing of their property by will, than they do under the English law, and it may even be urged that this liberty, by the complicated settlements or dispositions of which it admits, has materially restrained the free alienation of estates, and thus in some measure defeated its own object.

Will, Freedom of the. The doctrine of the freedom of the human will is generally maintained as the antithesis to the doctrine of Necessity. The difficulty of the doctrine is felt only in reconciling it to absolute foreknowledge in God. This difficulty Professor Mansel meets by saying that (like eternity and continuous duration, everlasting purpose, and accessibility to prayer, perfect action yet unexhausted power to act), 'complete foreknowledge, coexisting with human freedom, may be classed among elements which we cannot combine into a single whole, but which we can believe are capable of such combination.' Professor Bain, on the other hand, in his work on *The Emotions and the Will*, asserts that this position involves a complete misapprehension of the terms of the question, and maintains that the words *liberty* and *necessity* are utterly misapplied in speaking of human will and action, these terms being metaphors converted into scientific language, while the mental processes to which they are referred may, with as good reason, be described as 'circular or oval, wet or dry.'

Williamite. [WILHELMITE.]

Williamsite. A variety of Serpentine met with, of a pale green colour, at Haroldswick, in Unst, one of the Shetlands, with chromate of iron; and also at Westchester, in Pennsylvania, where it was first discovered by L. Williams, after whom it is named.

The name Williamsite has also been applied by some mineralogists to the native silicate of zinc, Wilhelmite or WILLEMITE.

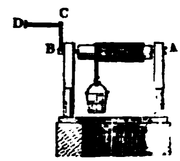
Willow. [SALIX.]

Wilson's Theorem. This theorem expresses a characteristic property of prime numbers, and may be thus ennunciated: The continued product, increased by unity, of all the integers less than a given prime is exactly divisible by that prime. Thus $1+1.2.3.4.5.6 = 721$ is exactly divisible by 7. No composite number could possess this property, since, being obviously a divisor of the continued product in question, it must necessarily be prime to that product increased by unity. Wilson's theorem may be easily deduced from FERMAT'S THEOREM; its demonstration is given in all text-books.

Wilsonite. A mineral of a rose-red or peach-blossom colour, named after Dr. Wilson, by whom it was discovered in the township of Bathurst in Canada. It bears some resemblance to Scapolite, and is a hydrated silicate of alumina, with potash and small quantities of soda and lime.

Wiluite. A name given to Grossular, from its occurrence near the river Wilui, in Siberia. [GARNET.]

Winch. A machine used for many common purposes. It is a particular modification of the wheel and axle, the power being applied by means of a rectangular lever or cranked handle. The arm B C of the winch represents the radius of the wheel; and the power is applied to C D at right angles to B C. This is the simplest form of winch, and is used for drawing water out of wells or foundations, and for other simple purposes. But for lifting heavier weights, wheel work is introduced into the construction of the winch, and, in many cases, small steam engines are employed for driving it. Steam winches are much employed in modern vessels for the removal of cargo from the holds.



Winchester Bushel. The local importance of Winchester, as the capital of the southern Anglo-Saxons, is illustrated by the universality with which the bushel of this city was accepted in the middle ages, and the steadiness with which it held its ground against the Windsor or royal bushel.

The Winchester bushel of 2150·42 cubic inches was the legal measure for centuries. The executive, from the time of the Anglo-Norman kings, gave such pains as they could in order to secure exactness in this measure. Thus, as early as the time of Richard I. it was provided that bushels should have iron rims, so that no fraud should be practised on buyers and sellers. The assize of measures was a perpetual matter of supervision in the manor court. The delinquencies of more important persons were chastised by other remedies. The inspection of measures was part of the coroner's duty, and even of the justices in eyre. Negligence in exacting due conformity to the various statutes which regulated measures would, in the case of the lord of a fair or market, work a forfeiture.

There are not, it appears, any existing measures more ancient than the reign of Henry VII. One, which was asserted to have been as

old as the days of King Edgar, and which is figured in Milner's *Antiquities of Winchester*, has, it seems, disappeared. But there are two measures of the reign of Henry VII. preserved in the Exchequer Office, one of which, being that of 12 Henry VII., contains about 84 cubic inches less than the imperial bushel, and about 26 cubic inches less than the modern Winchester standard. Another, preserved in the museum at Winchester, is only about 3 cubic inches less than the amount named above as representing the quantity of the Winchester bushel. There is a Winchester peck, also, in the Ashmolean Museum, at Oxford, which is even larger than the imperial standard.

It is said that the standard of Elizabeth corresponded exactly with the standards of Edward III. and Henry VII. The origin of the Windsor bushel is to be assigned to the custom of *purveyance*, the crown purchasing by its own bushel and quarter, and taking an advantage of one in twenty. In course of time the quantity in excess was reduced, and the uneven imperial bushel stands to the old Winchester measure in nearly the proportion of 32 to 31.

The Winchester bushel is still used in the United States. For further particulars on ancient measures, see Professor Rogers' *Agriculture and Prices*, vol. i. ch. x.; and Short *On Weights and Measures.*

Wincing Machine. The reel by which the dyer winds various articles through the dyeing vat or copper.

Winds (Lat. ventus). Currents in the atmosphere conveying air with more or less velocity from one part to another. A contraction or expansion in one part of the atmosphere, such as is caused by a variation in temperature, or by an increase or diminution in the quantity of aqueous vapour suspended in the air, will disturb the equilibrium, and produce a wind.

The theory of winds is exceedingly complicated, but the collected observations of many years have enabled meteorologists to trace certain laws even in the variable and apparently irregular winds. The most general of these laws is the *law of rotation* enunciated by Dove. This observer has shown that, from the two main currents of air—one from the poles to the equator, and the other from the equator to the poles—all other winds are derived, the modifications being caused by the relative distribution of land and water.

Winds may be divided into three classes: 1. Permanent winds, as the trade winds of the torrid zone. 2. Periodical winds, as the monsoons of the Indian Ocean. 3. Variable winds, as the winds of the temperate and frigid zones.

Permanent Winds are the winds of the torrid zone, which are caused by the solar heat and the rotation of the earth. If the earth were a sphere of uniform temperature, and at rest in space, the atmosphere would also be at rest; its height would be constant over every point of the earth's surface, and its density and elasticity at equal altitudes everywhere the same. But if the temperature of the motionless sphere, instead of being equal at every point, were greatest at the equator, and decreased towards the poles, then, though the pressure on every point of the surface would still continue the same, the altitude of the atmospheric column would become greatest at the equator, and consequently its specific gravity less there than at the poles. The heavier fluid at the poles would then, by virtue of its greater weight, pass beneath and displace the lighter, and a current be established in the lower part of the atmosphere from the poles towards the equator. In the higher regions of the atmosphere the effect would be reversed. The lower stratum of air in the equatorial regions being heated by its contact with the earth, becomes rarefied and ascends, and thus produces an accumulation, and causes a counter current in the higher regions from the equator towards the poles.

If we now suppose the sphere to revolve about its polar axis, an apparent modification will take place in the directions of the currents. If we consider places of different latitudes on the sphere, we find the velocity increases as the cosine of the latitude in going from the poles to the equator. A wind coming from the north will have a less velocity east than the places which it enters, and will, in consequence, be deflected towards the west. Thus the lower current, which, if the earth were at rest, would blow from the north, in consequence of the rotation of the earth, blows from a point more and more east. With the upper current exactly the opposite takes place. The air is thus carried back to the quarter whence it came, having veered all round the compass, blowing mostly in one direction, viz. that of the sun. This is the theory of the *trade winds*, which prevail within and to a considerable distance beyond the tropics in both hemispheres. These currents, however, receive important modifications, both as to their direction and the distance to which they extend, from the variation of the sun's declination and the configuration of the land. They prevail in the open ocean, in the Atlantic and Pacific, between the latitudes of 30° N. and 27° S. On entering this zone from either side, the deviation arising from the rotation of the earth towards the east is greatest; and this deviation becomes less and less as the equatorial zone is approached. In the immediate vicinity of the zone, the wind is nearly due north on the northern side of the equator, and nearly due south on the southern side. [TRADE WINDS.]

The zone of maximum temperature separates the circuits of the northern and southern currents of cold air, so that each current performs its own circuit. All places between the tropics will be for part of the year in the northern trade wind, and for part of the year in the southern trade wind. These periods are separated by intervals at which there is no particular direction of the wind. At the equator, both the northern and the southern currents are of the same length; north of the equator,

the northern current is the longer; south of the equator, the southern current is the longer; and at the tropics only one current occurs, interrupted by a calm at the time of the solstice.

The place of meeting of the northern and southern currents is thrown north of the equator, for, owing to the unequal distribution of the land, the mean temperature north of the equator is higher than that south of the equator, and consequently the relative masses of air in the two hemispheres differ.

The existence of an upper trade wind was first asserted by Halley in 1686. The upper trade wind has not been reached in the torrid zone; nevertheless, its existence has been proved beyond dispute. On the 30th of April, 1812, after an explosion had been heard at Barbadoes, ashes fell so thickly as to break down the trees. The trade wind was at its height, and it was concluded that these ashes came from the volcanoes of the Azores. They came, however, from St. Vincent, 100 miles to the west. The violence of the eruption had carried the ashes through the lower trade wind to the upper. On the 20th of January, 1835, the volcano Coseguina, on Lake Nicaragua, burst into eruption with a report which was heard 1,000 miles off. Clouds of ashes enveloped the seaport town Union, on the west of the bay of Conchagua, and caused darkness for forty-three hours. Ashes also fell at Kingston and other places in Jamaica, which is N.E. of Nicaragua; hence they must have been carried by the counter trade wind. These and similar facts prove the existence of an upper current.

The upper trade, as it passes northward into cooler regions, sinks gradually to the earth, and forms the prevailing W. and S.W. winds, which makes the sailors call the journey from Philadelphia to England *down hill*. At the Peak of Teneriffe it grazes the summit of the mountain, and all travellers who have visited the peak speak of the strong S.W. wind they encounter at the summit. But the place at which the upper current reaches the earth varies with the position of the sun. It descends to the surface in summer in somewhat higher latitudes than it does in winter.

As we have already remarked, the *law of rotation* of Dove is based on the assumption that there are, properly speaking, only these two atmospheric currents on which our relations of weather depend, a polar and an equatorial current. 'Within the tropics these currents flow one over the other; but beyond the tropics they flow beside each other in variable channels; and it is the preponderance of one of these currents over the other at a given place which determines extreme circumstances or conditions in respect to temperature, and their contest and alternate prevalence which determines the changeable character of the weather of our own countries. The *law of rotation*, as deduced from observations, is thus stated by its author: 'In the northern hemisphere, when polar and equatorial currents succeed each other, the wind veers, in general, in direction S., W., N., E., S. round the compass. Exceptions to this rule are more common between S. and W. and between N. and E. than between W. and N. or between E. and S. In the southern hemisphere, when polar and equatorial currents succeed each other, the wind veers, in general, in direction S., E., N., W., S. round the compass. Exceptions to this rule are more common between N. and W., and between S. and E., than between W. and S. or between E. and N.' (Dove *On the Distribution of Heat over the Surface of the Globe.*)

Periodical Winds.—In the Indian Ocean the trade winds receive a curious modification from the position of the surrounding land, and the effect of the solar heat on it. During one half of the year, from November to April, the winds blow in the ordinary direction of the trades, i. e. from the N.E.; but from April to November they blow in the directly opposite direction. This phenomenon is thus explained. The place of meeting of the two trade winds varies with the position of the sun; consequently, at places between the limits of this variation periodic winds blowing in exactly opposite directions are produced. These winds are called MONSOONS. The S.E. trade wind, as we have seen, owes its easterly direction to the fact that it moves towards points which have a greater velocity than the points from which it blows. These conditions are changed as soon as the wind crosses the equator, and the S.E. trade wind becomes the S.W. monsoon. Similarly the N.E. trade wind becomes the N.W. monsoon.

Between the equator and 10° south latitude, N.W. winds prevail from October to April, and S.W. the rest of the year. In other parts of the tropics, the regular trade winds are also modified by the configuration of the land. On the coast of Guinea the wind almost constantly blows from the S.W., in the opposite direction to the trades. Near the Cape Verd Islands calms and variable winds are usually experienced. Between the parallels of 30° and 40°, in both the North and South Pacific Oceans, westerly winds blow almost constantly, excepting only for a short time after each equinox. In the North Atlantic Ocean the prevalence of westerly winds between those parallels is less constant, in consequence of the comparative narrowness of that ocean, and the consequent influence of the opposite continents; they are still, however, the prevailing winds, except in the months of April and October, when a N.E. wind is more frequent.

Variable Winds.—According to the *law of rotation*, even the variable winds of high latitudes are merely occasional deviations from the two main directions. Beyond the trade wind zone, these winds continue to move in parallel channels. 'The characteristic differences of these currents may always be traced to their difference of temperature, and to the differences in the action exerted by the earth on them in their course.' When the two opposite currents come into collision, a rotatory motion is often produced; and thus arise revolving storms or *cyclones*. [STORM.] It is a disputed

point whether the storms of the British Isles occur according to this rotation theory. Sudden and violent local winds are produced by the rarefaction which attends the precipitation of aqueous vapour. The condensation into drops creates an immense void, the filling up of which must necessarily occasion violent atmospheric changes. Hence it is that an unusual fall of the barometer is generally followed by a gale of wind.

The different manner in which land and water are affected by radiation and the direct heat of the sun gives rise to the *land* and *sea breezes* which prevail on the coasts. They occur chiefly in tropical countries, though they are not confined to any particular latitude, and are perceptible sometimes as far north as Norway. During the day the surface of the land becomes more heated than that of the adjacent ocean, and the air over the land, in consequence of its greater rarefaction, is displaced by the denser air rushing from the sea. Hence a current, or *sea breeze*, beginning at some hour in the morning, and continuing till the sun is near setting, will flow from the water towards the land. At night the water remains warm, while the surface of the land cools rapidly; and hence the current sets from the land towards the water, and forms the *land breeze*. Winds of this sort are more frequent about islands and small peninsulas than in other situations. In mountainous districts periodic daily breezes also occur, probably produced by the copious nocturnal radiation from the summits of the mountains.

A variety of local winds have received particular names. The *Etesian* is a northerly or north-easterly wind, which prevails very much in summer all over Europe. The *Sirocco* is a hot, moist, and relaxing wind, which visits Naples and the south of Italy from the opposite shores of the Mediterranean. The *Samiel* or *Simoom* of Arabia is a hot, arid, pestilential blast, generally coming from the south. The *Kamsin* of Egypt is of the same kind. The *Harmattan* is a dry east wind, also of an unwholesome character, occurring in Guinea and some other countries.

Velocity of the Wind	Perp. Force on 1 Sq. Foot, in Lbs. Avoirdupois	Common Appellation of the Force of such Winds
Miles in an Hour		
1	·005	Hardly perceptible.
4	·079	Gentle pleasant wind.
5	·123	
10	·492	Pleasant brisk gale.
15	1·107	
20	1·968	Very brisk.
25	3·075	
30	4·429	High wind.
35	6·027	
40	7·873	Very high.
50	12·300	A storm.
60	17·715	A great storm.
80	31·490	A hurricane.
100	49·200	A violent hurricane.

The velocity of the wind varies from almost nothing to upwards of a hundred miles an hour; but the maximum is variously stated by different experimenters. In vol. li. of the *Philosophical Transactions* a table is given of the different forces and velocities of winds, drawn up by Smeaton from a considerable number of facts and experiments, by the assumption that the pressure varies as the square of the velocity. An extract from it is given above.

(Prof. Forbes' *Reports on Meteorology* to the British Association for 1831 and 1840; Experiments by Col. Beaufoy in the *Annals of Philosophy*, vol. viii. p. 94; Daniell's *Meteorological Essays*; Murray's *Geography*, Introd.; Pouillet, *Elémens de Physique*; and *Greenwich Meteor. Obs.*; Dove *On the Distribution of Heat* and *On the Laws of Storms*; Colonel Reid *On the Laws of Storms*; *Meteorology*, by Jenyns; Herschel's *Meteorology*; Maury's *Physical Geography of the Sea*; Fitzroy's *Weather Book*; and Buff's *Physics of the Earth*, edited by Hoffmann.)

Wind-sail. A tube or funnel of canvas, employed to convey a stream of fresh air down into the lower parts of a ship.

Wind-gauge. An instrument for measuring the force or velocity of the wind. [ANEMOMETER.]

Windage. In Gunnery, windage is strictly the difference between the area of a section of the bore at right angles to its axis, and the area of a great circle of the shot. It is, however, generally estimated by linear measurement, and is then taken as the difference between the diameter of the bore and that of the shot.

Windlass. A contrivance used in many vessels, instead of a capstan, for raising the anchor or lifting other heavy weights. It usually consists of a horizontal polygonal beam of timber, supported at a short distance above the deck by strong uprights called *windlass-bitts*, and in the older forms of the machine it is rotated by means of short poles called *hand-spokes*, which are introduced into mortices in the body of the windlass, and by which it is turned round, winding up the chain-cable as it revolves. To prevent the windlass from turning back when the strain of the chain comes upon it, a strong ratchet-wheel is fixed on its centre, into the teeth of which a number of *palls*, hinged on an upright timber called the *pall-bitt*, fall as the wheel revolves. Modern windlasses are rotated either by wheel-work or by a ratchet or friction contrivance, moved by handles like those of a pump, which catch a wheel on the windlass and turn it round through a certain distance at each stroke. Brown's capstan, however, in which there is a suitable indented groove for receiving and holding each link of the chain-cable as the capstan revolves, is now usually preferred to the windlass.

Windmill. In Mechanics, a mill which receives its motion from the impulse of the wind, the oblique sails forming virtually a great screw of four threads, which the wind puts into revolution. The building containing the machinery is usually circular. To the extremity

of the principal axis, or wind-shaft, are attached rectangular frames, generally four, on which cloth is sometimes stretched to form the sails; but the sails are now more usually made of wooden lattice work, like Venetian blinds, which may be opened in high winds to let part of the wind through. The surfaces of the sails are not perpendicular to the axis, but inclined to it at a certain angle, about 72° at the extremities nearest the axle, and 83° at the further extremities; so that their form is in some degree twisted, and different from a plane surface. If we suppose the axis to be placed in the direction of the wind, the wind will then strike the sails obliquely, and the force may therefore be resolved into two parts, one of which, acting in the direction perpendicular to the axis, gives a motion of rotation to the sails, and consequently to the main shaft, from which it is communicated to the machinery. The main shaft is inclined to the horizon in an angle of from 8° to 15°, chiefly in order to allow room for the action of the wind at the lower part, where it would be weakened if the sails came too nearly in contact with the building.

As the direction of the wind is constantly changing, some apparatus is required for bringing the axle and sails into their proper position. This is sometimes effected by supporting the machinery on a strong vertical axis, the pivot of which moves in a socket firmly fixed in the ground; so that the whole structure may be turned round by a lever. But it is now usual to construct the building with a movable roof, which revolves upon friction rollers, and the shaft being fixed in the roof, is brought round along with it. The roof is brought into the required position by means of a small vane wheel furnished with sails, which turns round when the wind strikes on either side of it, and drives a pinion which works into the teeth of a large crown wheel connected with and surrounding the movable roof. This wheel will settle itself where there is the minimum of motion imparted to it, which will be in the line in which the wind is blowing; and the main sails are by this expedient constantly made to face the wind.

Of the Form and Position of the Sails.—From the investigations of Parent and Belidor, it appears that the maximum effect of the wind on the sails is produced when their inclination to the axis of rotation is about 54¾ degrees; or when the *angle of weather*, i.e. the angle formed by the plane of the sail and the plane of its revolution, is 35¼ degrees. But this result, being obtained from considering the effect of the wind on the sails when at rest, does not agree with that which is found by experiment. In fact, as the velocity of the sail tends to withdraw it from the action of the wind, it is necessary to counteract the diminution of force by diminishing the angle of weather, or to bring the sail into such a position that the wind may strike its surface more directly; and since the velocity of the different parts of the sail is in proportion to their distance from the axis, it follows that in order to produce the greatest effect every elementary portion of it ought to have a different angle of weather, diminishing from the centre to the extremity of the sail. Euler has given a theorem which determines the law of variation. Let a be the velocity of the wind, and b the velocity of any given part of the sail; then the action of the wind upon that part of the sail will be a maximum when the tangent of its inclination to the axis, or the cotangent of the angle of weather,

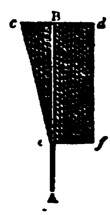
$$=\sqrt{2+\left(\frac{3\,b}{2\,a}\right)^2}+\frac{3\,b}{2\,a}.$$

Suppose that at a given part of the sail the velocity of the sail is equal to the velocity of the wind, we have then $a=b$; and the formula becomes

$\sqrt{2+\frac{9}{4}}+\frac{3}{2}=3{\cdot}561=$ tangent of 74° 19′, which gives 15° 41′ for the angle of weather.

This subject was investigated experimentally by Smeaton (*Phil. Trans.* vol. li.), who found that the common practice of inclining the sails from 72° to 75° to the axis is much more efficacious than the angle assigned by Parent, the effect being as 45 to 31. When the sails were weathered in the Dutch manner, or with their surface concave to the wind, and the angle of inclination greater towards the extremities, the effect was greater than when weathered either in the common way or according to Euler's theorem. But the effect was greatest when they were enlarged at their extremities, and had the form *c d f e*, represented in the annexed figure; so that *c d* was one-third of the radius A B, and *c* B to B *d* as 5 to 3. If the sails be farther enlarged, the effect is not increased in proportion to the surface; and besides, when the quantity of cloth is great, the machine is much exposed to injury from sudden squalls. In Smeaton's experiments the angle of weather varied with the distance from the axis; and it appeared from several trials that the most efficacious angles at the different parts of the sail were those in the following table:—

Fig. 1.



Parts of A B, which is divided into Six equal Parts	Angle with the Axis	Angle of Weather
1	72°	18°
2	71	19
3	72	18
4	74	16
5	77½	12½
6	83	7

If the radius A B of the sail be 30 feet, then the sail will commence at ⅙ of A B, or 5 feet from the axis, where the angle of inclination will be 72°. At 10 feet from the axis, the angle will be 71°; and so on, as in the table. In point of fact, the surfaces of windmill sails should be helical, or nearly so, while they

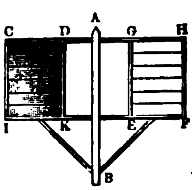
are in action. But as they are twisted somewhat by the action of the wind itself, the surfaces are not helical when at rest, but are more nearly so when in motion. In the best forms of mill, the Venetian work, of which the sails are composed, is so made that it is opened partly by the increased centrifugal force when the mill runs at a high speed.

Of the Effect of Windmill Sails.—The following maxims relative to the effect of the sails were deduced by Smeaton from his experiments:—

1. The velocity of windmill sails, whether loaded or unloaded, so as to produce a maximum effect, is nearly as the velocity of the wind, their shape and position being the same. 2. The load at the maximum is nearly, but somewhat less, as the square of the velocity of the wind, the shape and position of the sails being the same. 3. The effects of the same sails at a maximum are nearly as the cubes of the velocity of the wind, but somewhat less. 4. The load of the same sails at the maximum is nearly as the squares, and their effects as the cubes of their number of turns in a given time. 5. When the sails are loaded so as to produce a maximum effect at a given velocity, and the velocity of the wind increases, the load continuing the same, then the increase of effect, when the increase of the velocity of the wind is small, will be nearly as the square of those velocities; when the velocity of the wind is doubled, the effect is nearly as 10 to 27½. When the velocities compared are more than double of that where the given load produces a maximum, the effects compared increase nearly in the simple ratio of the velocity of the wind. 6. In sails where the positions and figures are similar and the velocity of the wind the same, the number of turns in a given time will be reciprocally as the radius or length of the sail. 7. The load at a maximum that sails of a similar figure and position will overcome at a given distance from the centre of motion will be as the cube of the radius. 8. The effects of sails of similar figure and position are as the square of the radius. 9. The velocity of the extremities of Dutch sails, as well as of the enlarged sails in all their usual positions, when unloaded, or even loaded to a maximum, is considerably quicker than the velocity of the wind.

Horizontal Windmills.—Windmills are sometimes constructed in such a manner that the planes of the sails intersect each other in the wind-shaft, in which case they are called *horizontal windmills*; because the wind-shaft being usually vertical, the sails have a horizontal motion. In this construction A B is the wind-shaft or arbor, which moves upon pivots. Cross-bars are fixed in this arbor, which carry the frames C D I K and G H E F. The sails

Fig. 2.



C K and G F are stretched on these frames, and are carried round the axis A B by the perpendicular impulse of the wind; and a toothed wheel fixed upon the arbor gives motion to the machinery. Two sails only are represented in this figure, but there are always two others at right angles to these. When the wind impels the two sails C K and G F equally, it is obvious that no motion can ensue. In order, then, that motion may be communicated to the machine, the impulse of the wind on the returning sail must be removed, either by screening it from the wind, or by making it present a less surface when returning against the wind. The first of these methods is said to be practised in Tartary, Persia, and some provinces in Spain. The other method was contrived by Hooke, and acts in the same way as a feathering paddle-wheel. Horizontal windmills, however, are greatly inferior to vertical, and even the last are going out of use, the steam engine being so much preferable as a prime mover, and being now so widely available.

Window (Dan. vindue, Span. ventana). In Architecture, an aperture in a wall for the admission of light and air to the interior. In distributing windows so that there be had a sufficiency of light, it is usual to make the piers or intervals between them never less than the width of the window, and never more than two widths of the same. Where it is required to ascertain the total area of light necessary for a room, the following empirical rule is frequently used: Multiply together the length, breadth, and height, and extract the square root of the product, which will be the area of light required.

Window Tracery. [Tracery, Window.]

Wine (Lat. vinum, Gr. *οἶνος*). The fermented juice of the Grape Vine, *Vitis vinifera*. The alcoholic strength of wine depends on the amount of glucose or grape sugar contained in the must; its flavour on certain essential oils produced in the grape itself when it has reached maturity, or perhaps on some ethers developed at once in the process of fermentation, or more slowly as the wine ripens by age. The latter is probably the true explanation of what is called the *bouquet* of wine, for common wines, though they may be often kept for an indefinite period, do not improve by age, while the highest class of wines become, within certain limits, much better by keeping.

The home of the grape is apparently Syria. It will not flourish in tropical regions; and though it grows luxuriantly even in the colder portions of the temperate zone, it will not ordinarily ripen its fruit higher than at about the 42nd degree of latitude in the Old World, the isothermal line in the New World being lower. It was not, it seems, cultivated in the plains of Mesopotamia, and it appears to have been slowly introduced even into Italy, if we are to trust the accounts given of the simple life of the Italian peasantry in the second century B.C. It is said to have been brought into France by Probus; and, according to common report, the best vintages of that country are even now

obtained from spots which had been selected originally by Italian cultivators. Such, for instance, is the Romanie Conti of Burgundy.

The vine grows best on exposed hills, on a light, calcareous, and especially on a volcanic soil, and with a south-east aspect. The nature of the soil is everything with the wine produced; for while the produce of a particular spot may be of the highest market value, that which is grown a few yards from the mysterious boundary may be almost valueless. No analysis of the soil of the best vineyards has given any clue to this remarkable difference in produce. All that is known is matter of experience, though as the juice of the grape always contains a notable quantity of cream of tartar in solution, which is deposited as the wine ripens, it is clear that the soil must contain potash.

The manufacture of the wine, and the manipulation of the grape harvest, are matters of careful and anxious interest to the vine-grower. A bad vineyard will not, of course, produce good wine, but the produce of the best vineyard may be spoiled by bad management or unskilfulness. The vintages most famous in antiquity have become poor or worthless. Either other localities have been more favourable, or the skill of the vinedresser has declined in Italy and the Ægean, for certainly the modern Falernian and Chian wines are very poor. At present, with the exception of Monte Fiascone, there is hardly a good Italian wine in the market, and the vintages of grapes must be manipulated in a very different manner from that to which they are subjected at present before they attain any reputation. It would be impossible, however, in a work like this, to give any account of the various wines which in increasing numbers are commended to the British public. The reader will find abundant information in the *Commercial Dictionary*.

Use of Wine in England.—In early English history, almost all the foreign wine (for some was manufactured at home) was imported from Bordeaux. From the time of our Henry II. to the rupture of the peace of Bretigni, a period of more than two centuries, Guienne was a dependency of the English crown, the intercourse between this country and the whole western sea coast of France was constant, and the commercial relations were very close. Wine was very cheap, and lay within the means of all but the poorest classes of society, being sold freely and generally at from 2*d.* to 3*d.* the gallon in money of the time, this sum being the ordinary wages of a day labourer. After the conquest of Guienne, at the close of the fourteenth century, the price was doubled. Spanish and Greek wines were known, but were dear, and rarely imported.

The constant wars between this country and France, and the frequent interruption of commercial relations, made the wine trade subject to violent fluctuations; but claret, i.e. Red Bordeaux, was the common wine of people in England till the negotiation of the Methuen treaty practically excluded the weaker produce of France by the enactment of what was in effect a prohibitive duty. The treaty was reluctantly acceded to, even by the stanchest friends of the New Settlement. It caused great discontent in Scotland, but it is believed that its terms were evaded by smuggling, a practice which at this time generally fell in with the tastes and political sympathies of the Scotch, who were dissatisfied at being debarred from the use of their favourite beverage, and not disinclined to cripple the resources of the new dynasty by avoiding as far as possible any contribution to the revenue. For many a year the charges of the customhouses at Leith and elsewhere exceeded the receipts.

The exigencies of the wars of the eighteenth century, and finally of the great continental struggle, led, along with many other fiscal expedients, to the extension of the duties on wine. They were raised from 4*s.* 10*d.* on French and 3*s.* 1¾*d.* on Portuguese growths, at which they were in 1794, to 10*s.* 6*d.* on French and 6*s.* 1*d.* on Portuguese; and in 1804 to 13*s.* 9*d.* and 8*s.* 10*d.* It is hardly necessary to say that the effect was a great diminution in consumption (the duties being so absurdly high that they almost amounted to prohibitions); a considerable developement of smuggling, and a general substitution of spirits for wine. In 1825, however, the duties were reduced to 7*s.* 3*d.* on French, 4*s.* 10*d.* on all other foreign wines, and 2*s.* 5*d.* on Cape produce. In 1831 the duties on all foreign wines were equalised at 5*s.* 6*d.*, and Cape wines charged 2*s.* 9*d.*

In course of time a general demand was made that the wine duties should be reconsidered, many persons advocating a uniform tax of 1*s.* the gallon, others suggesting an ad valorem duty, others an alcoholic duty. The last of the plans, and obviously that which is the most practicable, and, under the circumstances, the most just, was adopted in 1860. It is clear that, especially in a commodity like wine, the market value of which depends on fashion, and varies with age, the imposition of an ad valorem tax would have been very difficult, if not impossible. The government, therefore, proposed that all wines containing 25 per cent. and upwards of proof spirit should pay 2*s.* a gallon, those which contained less 1*s.*, the avowed object of the change, concurrently with the negotiation of the French commercial treaty, being the encouragment of light wine consumption. Sufficient time has hardly elapsed since the change, to give any proof as to the success of the experiment; but the revenue has suffered very little loss, and bids fair soon to reach and exceed the amount derived before the change. It is singular, however, that although the alcohol contained in wine is much less lightly taxed than that in spirits, the consumption of the latter has greatly increased. The duty on bottled wines, put in 1860 at the highest rate, was in 1866 reduced in the case of wines below 25 per cent. to the lower rate, the change having been provided by the terms of the Austrian commercial treaty.

Wing (A.-Sax. gehwing). In Architecture. [Alæ.]

Wings. In Botany, certain membranous expansions of different parts of plants. The two lateral oblong petals of a Papilionaceous corolla, the two lateral sepals of a *Polygala*, the expansion from the back of the fruit of the Ash-tree, from the sides of the seed of a *Bignonia*, and from the surface of many Umbelliferous fruits, are all called *wings*; as also are the membranes sometimes projecting from the angles of certain stems or leaf stalks.

Wings. In Military operations, the flank portions of an army, as distinguished from the centre. Each regiment is also divided into two portions, called the *right* and *left wings*.

Wings. In ships, wings are passages along the sides of the ship between the fore and after cockpit, to give the carpenters ready access to any leak.

Wing-transom. In a ship with a square stern, that transom on which the main body of the stern rests.

Winna. An Indian name for layers of the dried bark of *Lecythis Ollaria*, used in Guiana as wrappers for cigarettes.

Winter (a Teutonic word). One of the four seasons of the year. Winter is usually understood to begin with the shortest day, and to end when the sun returns to the vernal equinox.

Winter's Bark. The bark of the *Drimys Winteri*, or *Wintera aromatica*, a large forest tree growing in Chili, Peru, and New Granada, and which was first brought to England by Captain Winter, who accompanied Sir Francis Drake, in 1578, to the straits of Magalhaens, where he obtained his specimens. It is found in the market in large quills or rolled pieces of a dull yellowish grey colour, and has an aromatic odour and warm pungent flavour. It was at first confounded with *Canella bark*, which it much resembles in appearance and flavour, but its inner surface is reddish brown, whereas that of Canella is much paler, and solution of sulphate of iron gives a precipitate in its infusion, but not in that of canella. Canella is the bark of the *Canella alba*, a large tree growing in the West Indies and America.

Winter-green. The *Chimaphila umbellata*, a plant which, under the name of *Pipsissewa*, was first used medicinally by the aborigines of America. The infusion of the dried leaves is tonic and diuretic. It has been found useful in some chronic affections of the urinary organs. The name *winter-green* is also given to Gaultheria.

Wipers. In some kinds of Machinery, as oil-mills, powder-mills, fulling-mills, pieces projecting generally from horizontal axles, for the purpose of raising stampers, pounders, or heavy pistons, in vertical directions, and then leaving them to fall by their own weight. The principal object to be attended to in the construction of wipers is to give them such a form that the weight shall be raised with a motion slow at first and gradually increasing in velocity, like that of gravity; and to this end the outline of the wiper should be a parabola.

Wire-drawing. The art of extending the ductile metals into wire. The operation is performed by casting or hammering the metal into a bar, which is then successively drawn through holes in a steel plate, each being smaller than the other, until the requisite fineness is attained. The holes through which extremely fine wires of platinum, gold, or silver are occasionally drawn, are sometimes made in a diamond or ruby.

Wisby, Ordinances of. Maritime laws, principally compiled from those of Oleron. (Hallam, *Middle Ages*, ch. ix. part ii.) [Maritime Law.]

Wiserite. A hydrated variety of native carbonate of manganese (Diallogite), named after the Swiss mineralogist Wiser. It occurs in yellowish or reddish silky fibres at Gonsenz, in Switzerland.

Wish. In Teutonic Mythology, the embodiment of fruition or actual enjoyment of desire, as distinguished from mere longing. It is thus an attribute of Odin, or rather may be considered as only another name for Odin, Wish being endowed with bodily shape and powers, and rejoicing in his own works, as a father rejoices in his children. The form used to express this attribute in the Edda is Oski; and thence the word *osk* is employed as a prefix, as in *oska-steinn*, a wishing-stone, *oska-byrr* (Gr. *ἴκμενος οὖρος*), a fair wind, i.e. such a wind as a man may wish for; *oska-barn*, a wish-child, i.e. an adopted child. Thus the heroes whom the *Valkyries*, or oska-mær, guide to the *Walhalla*, are Odin's oska-barn, or choice children. This power of wish marked the spear of Odin, the hammer of Thor, which after doing its work returned of itself to his hand, and the necklace of Freya, which answers to the cestus of Aphroditè. (Dasent, *Popular Tales from the Norse*, xciii.) In a remarkable Vedic hymn, cited by Professor Max Müller, in his *History of Sanscrit Literature*, p. 561, the same idea apparently is conveyed by the word *kama*, in describing the work of creation. This word, which he translates by the term *love*, Professor H. H. Wilson interprets as wish, or desire. (*Edinburgh Review*, Oct. 1860, p. 384.)

Wistaria (after Caspar Wistar, Professor of Anatomy at Pennsylvania). A genus of climbing shrubs of the order *Leguminosæ*, natives of North America, Japan, the northern provinces of China, &c. Two species are well known, and largely grown in this country for the sake of their elegant racemes of lilac flowers, which are produced in great profusion when the plant is trained over on a south wall or other sheltered spot. *W. sinensis*, the Chinese species, has larger and paler flowers than those of *W. frutescens*, the American kind, the flowers of which, moreover, are slightly scented, and have a greenish spot at the base of the standard.

Wistit. [Ouistitis.]

Wit (A.-Sax.; akin to Ger. wissen, Lat. videre, Gr. ἰδεῖν, *to see*, *to know*). Wit has been defined briefly to be the unexpected combination of distant resemblances. The term *wit* has in the course of two centuries passed through more significations than most others in the English language. Without going farther back than the reign of James I., wit is used by Sir J. Davies as the most general name for the intellectual faculties. In the time of Cowley and Hobbes, it came to denote a superior degree of understanding, and more particularly a quick and brilliant reason. By Dryden it is used as very nearly synonymous with *talent* or *ability*; but after his time, and more particularly by Addison in his papers on Wit, we find a gradual approximation to the modern signification of the term. (For the difference of meaning between *wit* and *bulls*, see *Edin. Rev.* vol. iii. p. 399.)

Witch of Agnesi. In Geometry, a curve of the third order, first noticed by Maria Gaetano Agnesi in her *Istituzioni Analitiche*, Milano 1748 (translated by Colston), and called by her the *Versiera*. The equation to rectangular co-ordinates is $xy^2 = 4a^2 (2a - x)$, whence the curve may easily be traced.

Witch Meal. A popular name given to the pollen or powder sold in the shops under the name of *Lycopodium*, procured from the *Lycopodium clavatum*, or *Clubmoss*. It contains a large quantity of oily inflammable matter, and when thrown into the flame of a candle produces a sudden flash or blaze, whence it is used in theatres for imitating lightning. It has also, from its yellow colour, been called *vegetable sulphur*. In Pharmacy, it is used for enveloping pills to prevent their adhesion.

Witchcraft. The craft, cunning, or science of the wise, the words *wizard* and *witch* being connected with the Teutonic wissen, and the Greek ἰδεῖν, *to know*. [WITENAGEMOT.] But the term has been practically confined to those who are supposed to have dealings with the agencies of the spiritual or unseen world, and who thus become endowed with preternatural powers, exercised sometimes for the good, but far more commonly for the injury of mankind. This was especially the mediæval sense of the word, and it rested undoubtedly on the hypothesis that witches were enabled to do certain acts wholly by virtue of a compact with the devil or his imps. But the word is also used by the translators of the Old Testament, and it has been asserted by some that the laws enjoining the capital punishment of witches are directed merely against poisoners. But the phenomena described in such cases as that of the witch of Endor closely resemble those of modern witchcraft, while they exhibit no trace whatever of poisoning. The league of the Jewish witches with familiar spirits still further attests the identity of Jewish notions on the subject with those which were entertained through the middle ages.

For the origin of the idea it is difficult, if not impossible, to account. The power which words have exercised on the mind when their original meaning has been in part or wholly forgotten is manifest to all students of the history of language. If confusions such as those between λευκός, *shining*, and λύκος, *a wolf* —both words belonging to the same root, the brute being so named from the glossiness of his skin—may possibly have supplied the germ of notions which were afterwards expanded into the superstition of LYCANTHROPY [LYCAON; WEREWOLVES], the mysterious wisdom ascribed to the sun as seeing into all the hidden nooks and crannies of the universe, and to Phœbus Apollo as the sun-god or light-god, may perhaps furnish a clue to the notion of a wisdom which, although not naturally attainable by man, may be acquired from superior beings. Thus in the Homeric hymn HERMES is described as seeking this boon at the hands of Apollo; and although the latter cannot impart to him all his secrets, yet he grants his prayer in part, and directs him to the Thriæ, who dwell far down in hidden dales, and who will reveal to him many mysteries.

As a method of accounting for certain alleged or assumed phenomena, the hypothesis of witchcraft is not less rationalistic than the opinion which denies the possibility of such phenomena, or of the agency by which they are said to be brought about. Although there seems to be no adequate warrant for the assertion that 'everyone everywhere and always prefers the less wonderful to the more wonderful of two explanations of the same fact,' it may be safely maintained that the theory of witchcraft is an attempt to trace certain supposed results to a cause. But the preference of a natural to a supernatural causation could not present itself as an alternative to men on whose minds the idea of any order or cosmos had not yet dawned. This intellectual state characterises pre-eminently those ages to which the earlier Vedic literature [VEDA] and the Homeric poems belong. To the men of this pre-historic age the phenomena of the outward world were all brought about by a conscious and personal agency; and although some of these phenomena were of frequent occurrence, there was no reason for this beyond the arbitrary will of the personal agents. Hence the same arbitrary will accounted at once for all unusual phenomena, and for these they looked with an impatient eagerness as assurances that these agencies were not dormant. Hence if the Homeric Greek could have been supplied with a philosophical history of the past, such a history would have appeared to him, in Mr. Grote's words, 'not merely unholy and unimpressive, but destitute of all plausibility or title to credence.' (*History of Greece*, part i. ch. xvi.) A comparison of the Greek with the Jewish mind will exhibit to a certain extent the same characteristics in both, and account for the resemblances of their popular belief.

But whatever may have been the origin of the idea, its universality can scarcely be called into question. It has taken root in all coun-

tries, and gives way but slowly before the experimental results of inductive science. In almost all countries also it has led in great measure to the same results of fear, credulity, gross injustice, and cruelty.

Among the Greeks, a general belief prevailed in magical practices and incantations, especially by women; and Thessaly was the region most celebrated for the pursuit of these arts by its inhabitants. The same superstition was equally prevalent among the Romans. But, in the sense in which the word is used in modern times, a witch is supposed to derive her power from a peculiar compact with evil spirits; and this species of witchcraft is of course posterior to the rise of Christianity. The first traces of the modern superstition respecting witchcraft are perhaps to be found in Augustine, who speaks of magicians as living in society with devils, and having a compact with them. The witchcraft of more ancient times became easily connected in vulgar belief with the superstitions arising out of Christian theology. As early as the council of Ancyra (308), the belief in transformations by magical art (of which we find so remarkable an instance in the romance of Appuleius) is condemned as heretical. The gods of the ancient mythology, by the zealous preaching of the Christian clergy, acquired in popular imagination the attributes of demons; and it is possible that many of the supposed assemblies of witches and devil worshippers, which terrified the imaginations of the chroniclers and historians of saints in the early part of the dark ages, originated in the secret meetings of the proscribed worshippers of pagan deities, who endeavoured to secure their privacy by terrifying their orthodox neighbours. About the time of Charlemagne and his successors, we find one species of witchcraft peculiarly prevalent. Storms and tempests were attributed to certain magicians (defensores), who were believed to have acquired a power of controlling the elements. The very general superstition (which also is mentioned by Augustine) of assemblies of females riding through the air with the demon Diana, Minerva, or Herodias (from which, in later days, the notions of the witch festival on the Brocken in Germany, the French sabbat, &c. were all derived), is also reprobated by the divines of this period. Up to this time we have found the church generally condemning many of the popular fancies respecting demoniac agency as superstitious; but from the end of the twelfth century we find them gradually gaining ground, so as to become articles of religious credence. At the coronation of Richard I. Cœur de Lion, Jews and women were forbidden to attend: the latter because so many of them were suspected of witchcraft. The works of Gervase of Tilbury (at the beginning of the thirteenth century) give perhaps the best picture of the extent to which similar opinions prevailed about that epoch. In the same century, witches and heretics were first connected in the eye of the church: the commissioners who tried the various sectaries of the time were equally directed to enquire into and punish magical practices. In the fourteenth century the persecution of witches assumed a more regular and severe character. The well-known accusations against the Templars (1309), in which all the common charges of compacts with the devil, witch-assemblies, &c., were mingled with those of atheism and heresy, were but the prelude to a long series of similar proceedings. About this time the south of France, north of Italy, and some parts of Germany seem to have been most infested with demoniacal agency. The female sex seems from the earliest times to have been most implicated in the public horror of witchcraft; and from the commencement of the fifteenth century the decrees of councils, &c. which speak of witchcraft, are principally directed against women. From this time, therefore, we may date the separation in popular belief of the higher magic practised by learned and distinguished men, from the petty witchcraft in which the performers were poor, old, and ignorant women. Many of the great magicians were believed to operate their wonders by the control which they had acquired over inferior spiritual agents, without any express compact with the devil; and although such practices were often condemned by the church, always liable to suspicion, and sometimes brought those who indulged in them (together with alchemists and astrologers) under the cognisance of criminal tribunals, yet they were always considered as of a different order from the feats of common witches. In 1484 appeared the famous bull of Innocent VIII. 'Summis desiderantes affectibus.' In this remarkable instrument all the absurdities of the popular superstition are formally recapitulated, and a commission directed to three judges (Institor, Sprenger, and Gremper) to examine and punish witches in the German empire. Although immediately relating to Germany only, this bull is rightly considered by Herzog (the author of the article on witchcraft in *Ersch and Gruber's Encyclopædia*) as forming a period in the history of this superstition. Although much cruelty had been already committed in the pursuit of this imaginary crime, it is from this solemn confirmation of the vulgar superstition that we must date the continuous course of legal persecution which lasted for two centuries over the greater part of Europe.

So merciless was the crusade against sorcery and witchcraft, that probably its victims may be regarded as falling not far short of the numbers slain in fair field in the wars of the middle ages. 'Seven thousand victims are said to have been burnt at Trèves, six hundred by a single bishop of Bamberg, and eight hundred in a single year, in the bishopric of Wurtzburg. At Toulouse, the seat of the Inquisition, four hundred persons perished for sorcery at a single execution, and fifty at Douay in a single year. In Italy a thousand persons were executed in a single year in the province

of Como, and in other parts of the country the severity of the inquisitors at last created an absolute rebellion. The same scenes were enacted in the wild valleys of Switzerland and of Savoy. In Genoa, which was then ruled by a bishop, five hundred alleged witches were executed in three months; forty-eight were burnt at Constance or Ravensburg, and eighty in the little town of Valery in Savoy.' (Lecky, *History of Rationalism*, ch. i.)

The details of these legal proceedings bear a striking similarity in all the countries in which this baleful superstition so long prevailed. It has been seen that by the bull of Innocent VIII. witchcraft was rendered a crime peculiarly cognisable by ecclesiastical authorities; so it remained for the most part in Catholic countries, especially where the Inquisition was established; and this constituted the chief difference between the procedure in those regions and that which prevailed in Protestant districts, where the civil magistrate took cognisance of the offence. Thus the various forms of religious observance which were interwoven with the judicial proceeding in the former, exorcisms and so forth, were for the most part disused by Protestants. In other respects, the mode of investigation and punishment was much the same. Everywhere they exhibited a singular mixture of legal refinement with popular violence. Thus the various ordeals by which suspected witches purged themselves (one of the most vulgar superstitions connected with witchcraft) were conducted with gravity and regularity under the eye of the law. The best known in England was that of water; if the accused swam when thrown in, it was held as a proof of guilt. On the Continent a favourite mode, among many others, was by weighing. In the scales set apart for this purpose, a true witch was always found to weigh more than her previously ascertained weight. When, however, the suspected person was in the hands of the tribunal, there was in general one only mode of procedure—by torture. And thus everywhere the witch persecutions produced the same result—confessions, viz., of all the strange and monstrous crimes with which the accused lay charged. These appear to have grown more voluminous and more utterly incredible in every generation; and this may be naturally accounted for: for when a witch had made up her mind to confess, it cost her nothing to promulgate the most extravagant inventions; and these being regarded as undoubted truths, formed the basis of interrogatories to be administered to other unhappy beings who might be brought under the same accusation. The punishment was uniformly death, usually at the stake.

On this subject Luther expressed himself with a fury singular even in his own age. In all such cases he could see no room for compassion. All must be burnt without exception. 'In England,' says Mr. Lecky, 'the establishment of the Reformation was the signal for an immediate outburst of the superstition, and there, as elsewhere, its decline was represented by the clergy as the direct consequence and the exact measure of the progress of religious scepticism. In Scotland, where the Reformed ministers exercised greater influence than in any other country, and where the witch trials fell almost entirely into their hands, the persecution was proportionately atrocious.'

It appears, upon the whole, that the persecutions during the sixteenth and seventeenth centuries were most violent in those countries which were the scene of much strife between the two religions, or in which the Calvinist opinions were pushed to an extreme—France, the Netherlands, Northern and Western Germany, Switzerland, Scotland, England under the Commonwealth, and at a still later period New England. A singular example of the contagion of fanaticism suddenly spreading with extraordinary violence, and subsiding again after one terrible outbreak, is to be found in the history of the witch persecutions in Sweden, in the end of the seventeenth century.

The fall of paganism supplied large nourishment for the superstition, which grew to its greatest height in mediæval Christendom. The converts to Christianity, whether in Southern or Northern Europe, were not taught to question the existence of their old gods, while they renounced their worship. In Mr. Grote's words, 'The heathen gods and goddesses, deprived as they were of divinity, did not pass out of the recollections and fears of their former worshippers, but were sometimes represented (on principles like those of Euêmerus) as having been eminent and glorious men, sometimes degraded into demons, magicians, elfs, fairies, and other supernatural agents, of an inferior grade, and generally mischievous castes.' (*History of Greece*, part i. ch. xvii.) The former was the case in the north, where 'the Christian logographers felt it their duty to point out the Odin and Thor of the old Scalds as evil demons or cunning enchanters who had fascinated the minds of men into a false belief in their divinity.' Thus the whole multitude of heathen gods, nymphs, fauns, satyrs, and other beings were numbered among the diabolical agents with whom sorcerers and witches entered into compact; and the whole strength of pagan superstition went to swell the sum of credulous ideas already afloat in the minds of the early Christians. 'Wherever they turned, they were surrounded and beleaguered by malicious spirits, who are perpetually manifesting their presence by supernatural acts. Watchful fiends stood by every altar; they mingled with every avocation of life, and the Christians were the special objects of their hatred.' (Lecky, *Rationalism*, ch. i.) It needed only the notion, that these demons had those on earth who were in league with them, to open the floodgates of persecution against the supposed conspirators.

The outburst of this persecution in the latter portion of the middle ages (for up to the twelfth century the chief weapons employed against

witchcraft were charm and incantation) is by Mr. Lecky connected with the change which passed over religious thought, gradually investing the Divine nature and government with a more harsh and gloomy colouring. The Albigensian revolt against sacerdotal domination, the proclamation of doubts touching the deeper questions of the faith by Abelard, and the influence of the philosophy of Averroes, led to a general idea that the reign of Antichrist had begun, and that Satanic agency was in a pre-eminent degree operating on the affairs of men. The idea of applying relics only to stay the plague was regarded with contempt. Sterner measures were indispensable. 'The inquisitors traversed Europe, proclaiming that the devil was operating actively on all sides; and among the very first victims were persons who were accused of sorcery, and who were, of course, condemned. Such condemnations could not make the belief in the reality of the crime more unhesitating than it had been, but they had a direct tendency to multiply the accusations.' The state of insecurity and despair thus produced was heightened by the desolating effects of the Black Death, which, regarded as a direct chastisement for the sufferance of witchcraft, supplied a fresh incentive to still more frightful persecutions and massacres. The superstition which prompted these atrocities was not weakened by the advice of Luther, that a child reputed to be begotten by the devil should be thrown into a river; and Luther's convictions were shared by the most learned lawyers and judges of his age. If the multiplication of the most monstrous and impossible charges, and of testimony drawn from perjured accusers and tortured victims, could prove the reality of a conspiracy, the fact of a league between sorcerers and devils was proved beyond all reach of doubt; and the conviction that this fact was proved retained its hold on the mind of John Wesley, who declared that all belief in the Bible must stand or fall with belief in witchcraft. But the idea that this conspiracy was a well-attested fact, was a mere delusion. The nature of evidence was at that time most imperfectly known; and it has been said, not without justice, that the judicial processes of the middle ages exhibit little more than a tissue of prejudiced judgments based on a besotted credulity. The evidence of witnesses, whose perjury would now be self-evident, was received without hesitation, while the accused were supposed to speak the truth of themselves and their accomplices while under excruciating bodily torment. When at length the frantic excesses of the persecutors had roused some faint scepticism as to the reality of the crime, writers could be found to declare that, if such a crime had not been proved to exist, nothing existed; while lawyers and judges, not iniquitous in other matters, declared themselves profoundly satisfied with the evidence of knaves and fools. Thus when the executions in Italy had roused some sceptical opposition, Spina fiercely complained that men were not only refusing to believe what they ought to believe, but were exerting all their influence to obstruct those who were destroying the enemies of Christ. (Sprenger, *Malleus Maleficarum*, i. 460 &c.) This smouldering opposition betrayed itself in the treatise of John Wier, *De Præstigiis Dæmonum*. Wier, not questioning the existence of demons, sought to prove that all reputed cases of witchcraft were instances of direct possession, and that, as the intermediate agency of a witch was superfluous, the crusade against sorcerers and witches was unnecessary, and therefore cruel. The self-accusations of women he accounted for by 'the credulity and fragility of the female sex.' Yet Wier, who had not sought to limit the region of the supernatural, was stigmatised by Bodin (*Démonomanie des Sorciers*) as one who had armed himself against God and written a tissue of horrible blasphemies. The practical conclusions of Bodin were summarily rejected by Montaigne, who declared it to be quite unnecessary to believe evidence, even when it was impossible to explain it away. 'This is setting a high value on our opinions,' he said, 'to roast men alive on account of them.' Thirteen years later, Charron, in his treatise *On Wisdom*, systematised the scepticism of Montaigne; and it was in this interval that Boguet, presiding at the tribunal of St. Claude, is said to have burnt six hundred persons chiefly for lycanthropy. In England, the first protest was raised in 1584, by Reginald Scott, who, in his *Discovery of Witchcraft*, 'exposed the atrocious torments by which confessions were extorted, the laxity and injustice of the manner in which evidence was collected, the egregious absurdities that filled the writings of the inquisitors, the juggling tricks that were ascribed to the devil, and the childish folly of the magical charms.' So little effect had this protest in the prevailing temper of the age, that the zeal of James I. carried a law subjecting witches to death on the first conviction, even though they should have done no harm to their neighbours.

This law was passed when Coke was Attorney General, and Bacon a member of parliament. Later still, when a century had passed away from the time of Reginald Scott's protest, the sceptical Glanvil strenuously upheld the popular belief in witchcraft in his *Sadducismus Triumphatus*, and won the warm approval of Henry More, Casaubon, and Cudworth. Glanvil, employing a line of argument much in vogue at the present day, urged the credulity of unbelief as a reason for accepting the reality of witchcraft. 'Analysing with much acuteness à priori objections, he showed that they rested upon an unwarrantable confidence in our knowledge of the laws of the spirit world; that they implied the existence of some strict analogy between the faculties of men and of spirits; and that, as such analogy most probably did not exist, no reasoning based on the supposition could dispense men from examining the evidence.' This evidence appeared to him as conclusive as to Reginald Scott it appeared worthless, while he forgot apparently that, on his own hypothesis, he had first to prove the exist-

ence of spirits as well as their operation in the manner alleged. But while books continued to be written in favour of the belief, the belief itself among educated men was practically on the decline. Still, when at one of the latest trials, that of Jane Wenham, in 1712, the judge treated with disrespect the rector of the parish, who declared, 'on his faith as a clergyman,' that he believed the woman to be a witch, the jury convicted. The judge obtained a remission of the sentence; but the clergy who had been her accusers vehemently reiterated their belief, and ended their protest with the words 'Liberavimus animas nostras.'

In Scotland the belief in witchcraft was more obstinate, and the horrors of witch persecutions perhaps reach their culminating point in the country where John Knox shaped the Reformation. 'As late as 1773 the divines of the Associated Presbytery passed a resolution declaring their belief in witchcraft, and deploring the scepticism that was general.' (Lecky's *History of Rationalism*, ch. i.; for the part taken by the clergy in fostering this superstition, see Buckle, *History of Civilization in England*, vol. iii. ch. ii.) The last victim capitally sentenced was put to death in 1722; but the practice lingered to a later time in some continental districts, as in Catholic Germany, Spain, and Switzerland. The subprioress of a convent was burnt at Würzburg in 1749; and the last, probably, of all the victims of this superstition, Anna Göldi, a domestic servant, was burnt at Glarus, in Switzerland, in 1782. A painstaking collection of learning on this strange subject will be found in Horst's *Zauber-Bibliothek*. (Grimm's *Deutsche Mythologie*, passim; Michelet, *La Torture*.)

Witches' Besoms. A name given to the bunches of branches altered from their original form, which are developed on the Silver Fir in consequence of the attack of a minute fungus, called *Peridermium elatinum*. The leaves as well as branches are altered in form from their first appearance, and soon fall, a new crop of infested foliage being produced each year from the buds. The fungus is apparently confined to the besoms.

Witches' Butter. The vulgar name of *Exidia glandulosa*, a dark brown or black jelly-like fungus studded above with little glandular points, and below rough like crape.

Witena-gemot (A.-Sax.). The great national council of the Anglo-Saxon nation, probably the direct representative of the popular assemblies of which Tacitus (*Germ.* xi.) speaks as existing among the old German tribes; the *folkmot*, or meeting of the whole tribe or nation, having in a larger territory and among a more scattered population become converted by a natural process into the *witena-gemot* or meeting of councillors. The meetings of the witan appear to have been attended by the king, by prelates and abbots, and sometimes by inferior clergy, by dukes and ealdormen, by milites ministri or thanes, many of whom were no doubt reeves or other royal officers in the shires. The witan was convened by the king either pro hâc vice or generally. Many acts or charters passed at its meetings are extant, and bear signatures (often from 90 to 100 in number), which may be assumed to be those of the members of the witan present, and which in fact form a principal source of our information on the subject. The witan, though not elective in the modern sense, was considered as representing the whole body of the people; but it is probable that the freemen in the neighbourhood were allowed to be present at its meetings, and exercised at least a right of assent to its decisions. According to Mr. Kemble, the witan (1) possessed a consultative voice and right to consider every public act which could be authorised by the king; (2) deliberated upon new laws, which were then promulgated by their authority and that of the king; (3) had the power of making alliances and treaties of peace, and of settling their terms; (4) had the power of electing the king; (5) had power to depose the king if his government was not conducted for the benefit of his people; (6) had, with the king, power to appoint prelates to vacant sees; (7) had power to regulate ecclesiastical matters generally; (8) had, with the king, power to levy taxes for the public service; (9) had, with the king, power to raise land and sea forces; (10) had the power of recommending, assenting to, and guaranteeing grants of lands; (11) had the power of adjudging the lands of offenders and intestates to be forfeit to the king; (12) acted as a supreme court of justice both in civil and criminal cases. (Kemble, *Saxons in England*.)

Withamite. A variety of Manganesian Epidote discovered by Witham, both massive and in minute but brilliant and transparent carmine-red crystals, lining small cavities in trap-rock, at Glencoe, in Argyleshire. It is a ferro-silicate of alumina.

Witherite. Native carbonate of baryta, named in honour of Dr. Withering, who first discovered it at Anglezarke, in Lancashire. It occurs amorphous and in six-sided crystals, resembling the common form of Quartz, and generally white, but sometimes of a greyish or greenish colour, at Alston Moor in Cumberland, Fallowfield in Northumberland, Dufton Fells in Westmoreland, &c.

Witherite is used in the manufacture of glass and china, and also in France in the manufacture of beet-root sugar.

Withershins. In the witchcraft of Scotland, this word (the German wiederschein) was used to denote the wrong or unlucky way of going round a person who was to be restored from sickness. The leech made the circuit, or dessil, round the couch of the sick man three times, moving from east to west, according to the course of the sun. To go round in the opposite direction was considered unpropitious.

Witness (A.-Sax. witnesse). In Law, one who gives evidence in a judicial proceeding.

In civil cases, witnesses are compelled to attend by the process called SUBPŒNA AD TESTIFICANDUM, and punishable, if they neglect to do so, by attachment or action. In criminal cases, the process is by subpœna or by recognisance taken by the magistrate before whom the information is given. [EVIDENCE.]

Wizard (akin to *wise* and *witch*). The popular name in England for a sorcerer. [WITCHCRAFT.]

Woad (A.-Sax. wad). The *Isatis tinctoria*, a plant which yields by the fermentation of its leaves a blue colouring matter resembling indigo. It is the *Pastel* of the French.

Woden. In Mythology, another form of the name of the Norse god ODIN, who with THOR stands at the head of the Teutonic pantheon. The name Thor appears in the forms Thunor (as in the A.-Sax. Thunres-dæg, *Thursday*), and Donner, *thunder*. His *hammer* seems to be the same word as the Greek Acmon, the Slavonic form of *hamar* being Kamen, and the Lithuanian akmu, akmens. (Bréal, *Hercule et Cacus*, 141.) The name *Woden* is preserved in the English Wednesday.

Wöhlerite. A columbate of zirconia, with silicate of lime and silicate of soda, found embedded in the zircon-syenite of Norway in crystals of various tints of yellow, inclining to red, brown, or grey. Named after Wöhler, the eminent chemist.

Wölchite. An arsenio-sulphide of lead, copper, and antimony, found in short rhombic prisms of a blackish lead-grey colour, in the iron-mines at Wölch, in the Lavant Valley, in Carinthia.

Wolf Fish. The name of a species of fish (*Anarrhichas lupus*, Linn.), which subsists on whelks and other shell-fish. It seizes its prey by means of strong conical slightly curved anterior teeth, set in the jaws like grappling hooks, and bruises by the action of very powerful posterior molar teeth.

Wolfram. Native tungstate of protoxide of iron, met with in the primary rocks of Cornwall, Saxony, and other countries, frequently associated with tin-ore. It occurs both massive and crystallised, of a dark-greyish or brownish black colour, with a brilliant (often metallic) lustre, and is sometimes feebly magnetic.

Tungsten is used for the manufacture of tungstate of soda, which affords a mordant in dyeing, gives hardness to plaster of Paris, and is the best material for rendering dresses incombustible. Added to steel, it possesses the property of imparting a degree of hardness to the alloy far greater than can be given to the metal when used alone. The name Wolfram (from Ger. wolferig, *eating*) has reference to the smaller quantity of tin obtained from the ores in which it is present.

Wolframium. [TUNGSTEN.]

Wolfsbane. The popular name of the *Aconite*, which is also called *Monkshood* from the shape of its flowers. In sufficient doses it is virulently poisonous, its most characteristic effects being the production of tingling and numbness, vomiting, contracted pupil, failure of the circulation, and occasional convulsion. Fatal results have sometimes occurred from mistaking this root for horseradish, to which, however, it bears little resemblance. It has been medicinally used with great success in some obstinate cases of *tic douloureux*, or *neuralgia*. Its powers are ascribed to the presence of the alkaloid *Aconita*. [ACONITE.]

Wollastonite or **Tabular Spar.** A silicate of lime which occurs generally in broad prismatic or laminar masses, but sometimes in distinct tabular prisms, from which it has derived the common name of Table or Tabular Spar. It is met with in white fibrous masses at Dunmore Head, county Down; at Glengairn, in Aberdeenshire; and in the basalt of the Castle Rock, Edinburgh. Named after Dr. Wollaston.

Women, Condition of. The social position occupied by women varies not only as communities are civilised or barbarous, but in communities which have reached the same point of civilisation. Nor is the respect felt for women to be measured always by race, for tribes or subdivisions of the same race give their women very different privileges and award them very different degrees of consideration. Race, however, is, on the whole, the chief cause for variety. Thus, among the negro and Malayan races, women are generally enslaved, perform all the hard labour of the field and the household, and are looked on as drudges. Among Semitic tribes, on the other hand, the women are secluded, and condemned to idleness and privacy, whenever the husband's wealth enables him to establish a harem; and even among persons of poorer condition, women are as far as possible concealed from public view. Among nations of Aryan origin, on the other hand, women are treated with respect, sometimes with great tenderness and honour.

In the earliest pictures of social life which we possess, the sacred books of the Jews, the Homeric poems, and the Hindu vedas, women appear to have held a far higher social position and to have had far more personal freedom than they afterwards enjoyed in the same countries or among the same people. The whole course of Jewish history indicates a very different position for the women of the people than that of the inmates of a harem or zenana, jealously closed and carefully guarded.

So again with the domestic life of the Greeks. The picture of the faithful Penelope, importuned by a number of suitors for her hand, vexed at their effrontery and riot, but never insulted or threatened; the loves of Hector and Andromache; the chivalrous sentiment felt towards Helen, though the author of so many griefs to Troy, point to a different social condition from that with which we are familiar in later times, when at Athens a woman's best reputation was to have no fame either for good or evil (Thucyd. ii. 45), when the education of women was discouraged lest they should

rebel against the authority of their masters, and when they were shut up in the inner part of the house, in all but Oriental seclusion.

The early literature of the Hindus gives similar testimony as to the equality of the sexes. A striking illustration of this equality may be found in Prof. Max Müller's *Ancient Sanskrit Literature*, p. 22, where a wife asks her husband what are the means by which she might reach that perfection which formed the chief object of those who strove to the honours of Brahmanical saintship, and expresses her conviction that conjugal love may be the means to this end. Her husband, who has just resolved to quit his home in order to devote himself to a life of contemplation, seeks to disabuse her of this impression, and says that 'a husband is loved, not because you love the husband, but because you love in him the Divine Spirit; a wife is loved, not because we love the wife, but because we love in her the Divine Spirit; children are loved, not because we love the children, but because we love the Divine Spirit in them.' And the speaker goes on to state that the course towards perfection is the same both for women and men, in strong contrast to the language used by the later sacred writings, in which women are treated as inferior, are precluded from any partnership in the family sacrifices, are forbidden to read the Vedas, or to assume the right of judgment on sacred things. A similar tenderness towards women is to be found in the early romantic dramas of the Hindus, such as the Sacontala.

The condition of women in ancient Rome was peculiar. The head of the house was the centre of all power and authority. The father had the right of life and death over his children, even after they were married and had households of their own. There was no escape from this authority, unless the son were thrice formally emancipated before the prætor. A married woman was greatly in the power of her husband and male relations, who could punish her with death for certain offences. But such a power did not accrue to the husband, unless the marriage took place in the solemn form called *confarreatio*. Hence, in course of time, as women were made independent, this solemn marriage became more and more rare, and at last was almost disused. The facilities of divorce, the licentiousness of the wealthy Roman matrons, and the general dissoluteness of Roman social life, are well known.

It was, however, among the German tribes that the greatest respect was paid to women. This fact was known to Tacitus, and commented on by him, for he speaks of these tribes as looking on women as possessed of a sort of inspiration. Of similar character also was the respect paid to their women by the Anglo-Saxons.

It is not easy to trace the origin of that chivalrous devotion towards women which constituted one of the best traits of the knightly character, and of that gallantry which ensued from the feeling. It was no doubt partly derived from the habits of race; it was probably increased by the quasi-religious character which belonged to most orders of knighthood. It became possibly still stronger by the contrast in which it stood to the treatment shown to women on the part of the Mohammedans, and which must have been taken note of in the time of the Crusades. For it is especially among Mohammedan nations, and in India among such communities as have imitated the social system without the faith of Islam, that the social position of women is the lowest, except, of course, among negro tribes.

Mr. Mill has of late years argued strongly that women should be, as far as regards the suffrage, on an equality with men. [REPRESENTATION.] It is singular that when the reformed mutineers of the Bounty established a constitution for their small settlement, they gave the suffrage to all adults, without distinction of sex, in the annual election of their chief magistrate. The rights which by English law a husband and wife have in each other's property, and the usual manner in which those rights are modified by agreement, are fully explained under MARRIAGE and SETTLEMENT.

For some singular customs attaching to women, and for regulations, intended, it would seem, on some occasions, to protect them, see Mr. E. B. Tylor's *Researches into the Primitive History of Mankind*, see also the treatise of Cornelius Agrippa, *De Excellentia Fœminini Sexus*.

Wonder-earth. [TERATOLITE.]

Wood (A.-Sax. wuda, Dutch woud). The solid part of the stems and branches of a plant, as distinguished from the pith which occupies the centre, and the bark which envelopes the whole. The wood of most trees, i.e. of all exogens, is formed in annual layers deposited below the bark, but on the exterior of the wood of previous growth. It consists of fibrous matter, called *woody tissues*, formed during the growth of the plant. Thus, when a seed germinates, and the plumule has become developed, it begins at once to send down fibres into the centre of the radicle, and these fibres constitute the first rudimentary wood. As leaves form and come into use, more perfect descending fibres are developed, these forming a cylinder of alburnum between the medullary sheath [MEDULLARY SHEATH] and the bark, and in this way, by the end of the first season of growth, there is formed a woody axis, surrounding the pith, and enclosed by the bark. The growth of the wood of a timber-tree is but a repetition of this process year after year.

It has been observed that wood is formed in annual layers, which layers, though not separable from each other, are seen in the grain of the wood when cut, so that by counting the rings of wood in the trunk of an exogenous tree, its age may be pretty clearly ascertained. In the accompanying figure, these layers are distinctly visible. The pith is shown at *a*, and the bark at *b*, while *d e* and *f* represent three

distinct layers of wood. In the end section the medullary rays [MEDULLARY RAYS] are evident, radiating from the centre outwards. The first year there is the pith, bark, and one ring of the wood formed (*a*, *b*, *d*). The second year new matter is deposited between the bark and the wood already formed; this consists of a viscous mass called *cambium*, which is gradually organised, and separates into two parts, the one forming an addition to the wood, the other to the bark. The third year new matter is again similarly interposed, while the old bark is pushed out and ruptured, and is gradually replaced by the new layers.

At the age of a few years wood acquires a different colour from that which it first possessed. It is then called *Heartwood* or *Duramen*. In the Beech, this is light brown; in the Oak, deep brown; in Brazil-wood and Guaiacum, green; and in Ebony, black. In all these it was at first colourless, and it owes its different tints to matter deposited gradually throughout its tissues. That part in which no such colouring matter is yet deposited, the portion exterior to the heartwood, is called *Sapwood* or *Alburnum*.

The wood of endogens differs from that of exogens in not being formed in concentric layers. It has no distinction of pith, wood, and bark, nor any medullary rays, and consists of bundles of woody fibres, dispersed irregularly among a mass of lengthened cellular tissue, the bundles being more crowded towards the circumference.

The value of wood, in the constructive arts, depends upon the toughness and cohesion or compactness of its tissues, that which has been most quickly grown being, cæteris paribus, of the best quality. The different colours, smell, and taste of different kinds of woods, are imparted by their peculiar resinous, gummy, or oily secretions. The colouring matter is sometimes deposited in such abundance as to render it useful for dyeing, as in the Logwood. Some woods have deposited in them volatile oils, which render them odoriferous, as in the Sandalwood; and bitter and other secretions give them a medicinal value, as in the Quassia.

Wood Coal. A synonym of BROWN COAL, and also of Cannel Coal.

Wood Engraving. [ENGRAVING.]

Wood Opal. A variety of Opal with a peculiar ligneous structure, which is made into snuff-boxes and other ornamental articles, at Vienna. (Bristow's *Glossary of Mineralogy*, p. 411.)

Wood Spirit. Crude wood spirit is now mixed by the excise to the extent of ten per cent. with alcohol; and the mixture, under the name of *methylated spirit*, is then allowed to be sold free of duty. [PYROXYLIC SPIRIT.]

Wood Stone. Petrified or mineralised wood. [WOOD OPAL.]

Wood Tin. Fibrous oxide of tin. An opaque, fibrous, and nodular variety of Cassiterite or Tin-stone, of a brown colour, and presenting a ligniform appearance, which is met with only in a few Cornish mines and in some of the principal stream-works of that county.

Woodbine. The Honeysuckle, *Caprifolium Periclymenum*.

Wooden Bottoms. [SABÔT.]

Woodlock. A block of wood nailed on each side of a ship's rudder to prevent it from being lifted off its hinges and unshipped.

Woodroof. The common name for the fragrant *Asperula odorata*, sometimes called Woodrow or Woodruff.

Woody Fibre. In Vegetable Physiology, the name given to very slender transparent membranous tubes, tapering acutely to each end, lying in bundles in the tissue of plants, and having no direct communication with each other. They are of extreme tenuity, and form the substances called *hemp* and *flax*. The same tissue forms wood.

Wool (A.-Sax. wul). In Commercial language, this term is applied to the hair of the alpaca, the goat, the beaver, the rabbit, and to similar substances, for weaving or felting; but strictly it belongs to the sheep only, the hair of which has, from time immemorial, been woven into cloth. According to Thucydides, however (book i.), the use of woollen garments was subsequent, in Athens, to that of linen. But woollen clothing is frequently mentioned in the Homeric poems.

In the middle ages, and especially in the thirteenth and fourteenth centuries, the best wool was produced in this country, part being exported to the Netherlands, part consumed in the home manufactures, the seat of which was at that time principally Norfolk, though cloths were woven in the West of England and in Ireland. The wool was of very different qualities, the best coming from Shropshire and Derbyshire, the worst from the mountain pastures of Westmoreland, and from the South Downs. It is probable that the great excellence and abundance of the English wool was in the main due to the comparative effectiveness of the police of this country, or, as it was styled, to the maintenance of the king's peace. As a sheep is of all animals the most defenceless, and on the whole the most eatable, it was difficult to rear flocks during those times of feudal anarchy in which France and Germany were ravaged by the companies and the Rhenish barons. At any rate, existing specimens of mediæval cloth, of the date of which there can be no doubt, do not indicate a very high quality in the wool of which they are composed.

The export of English wool was so important a matter to the Flemish manufacturers, that the foreign policy of the two countries during the fourteenth and fifteenth centuries was mainly determined by the wool trade. The supply of English wool drew James Arteveldt into his alliance with Edward III. The prosperity of Flemish manufactures was the object which in great measure determined the policy of the duke of Burgundy in the beginning of the fifteenth century. The risk of checking this prosperity put a stop to the intrigues of Mary, duchess of Burgundy, at the conclusion of the same period. Concurrently with these foreign relations, the English government strove, and with some success, to encourage a home manufacture, and therefore occasionally prohibited the export, or regulated it, or fixed the price of the article, or defined the places at which it should be sold. So important was the produce that it frequently formed the material of a tax; and the grant of some thousands of sacks, or a tithe of fleeces, was a familiar subsidy. The taxes levied on this principle give us an insight into the distribution of wealth in England; and the licenses to export denote generally the value of the produce in different localities. [TREATY, COMMERCIAL.]

English sheep are said to have been exported to Spain—the date for the transaction is not to be found—in pursuance of a treaty, and in exchange for Spanish horses. It is stated that this flock was the origin of the merino wool, for which Spain was so famous. At the beginning of the present century, some of the descendants of these sheep were taken to Germany, and produced the fine wools of Saxony. The belief, however, in the vast superiority of English wool, induced the legislature to place heavy restrictions on its exportation, and to continue these by penalties made increasingly severe, and ultimately capital, long after this superiority had passed away. It was only in 1825 that the prohibition laid on the exportation of British wool was abolished, abundant evidence being given that the English manufacturer made no gain by the prohibition, and that the agriculturist suffered a serious loss.

No duty was levied on foreign wool up to the year 1802, when it was subjected to a tax of 5*s.* 3*d.* per cwt. The tax was raised to 6*s.* 8*d.* in 1812, and increased by Mr. Vansittart, whose name is to be identified with every conceivable folly in finance, to 56*s.* per cwt., i.e. 6*d.* per lb. Fortunately his policy was reversed by Mr. Huskisson in 1825, when colonial wool was made free, and foreign wool subjected to an ad valorem duty of 1*d.* if worth more than 1*s.* the lb., or ½*d.* if less. In 1840 foreign wool was freed from duty.

Excellence in wool is seldom attained concurrently with excellence in the flesh of the sheep, and thus improvements in the herd are fatal to the fineness of the fleece, to the softness of the hair, and the length of the fibre. Nor is the climate of this country so favourable to the growth of the best wools as that which is hotter and drier. Hence the superiority of merino, Saxony, and finally Australian wools. Up to the time in which the elector, afterwards the king of Saxony, developed the produce of wool in his dominions, Spanish wool was the best; but after the introduction of Saxony wool, the Spanish imports rapidly declined. Since the introduction of sheep farming on an extensive scale in Australia, the Saxony produce has undergone a similar fate. Latterly, the employment, and consequently the production, of wool has received a powerful stimulus by the comparative scarcity of cotton. (*Commercial Dictionary.*)

The various processes of the woollen manufacture, as at present carried on, are more numerous and complex than those of any other of our textile manufactures; but our limits do not allow us to specify them.

Many methods of cheapening woollen cloths have been introduced. [MUNGO; SHODDY.] Among these may be mentioned the use of cotton warps with woollen woofs. Cloths with cotton warps are generally called *union cloths.*

Mr. Baines' Estimates of the Annual Value of the Woollen Manufacture of the United Kingdom, 1858.

(1) Raw material—		
lbs.		£
75,903,666	foreign and colonial wool .	4,717,492
80,000,000	British wool at 1*s.* 3*d.* per lb.	5,000,000
	Shoddy and Mungo—	
45,000,000	{ 30,000,000 lbs. shoddy at 2½*d.* per lb. . . . . 15,000,000 lbs. mungo at 4½*d.* per lb. . . . . }	609,370
	Cotton and cotton warps, $\frac{1}{10}$ of the wool	206,537
200,903,666		£10,533,399
(2) Dye-wares and soap		1,500,000
(3) Wages—150,000 work-people at 12*s.* 6*d.* per week		4,875,000
(4) Rent, wear and tear of machinery, repairs, coal, interest on capital, and profit—20 per cent. on the above		3,381,680
	Total	£20,290,079

Woollen Manufacture, Middle Ages.—The chief seat of the woollen manufacture of England 500 years ago was Norfolk, especially at the towns of Norwich, Aylesham, and Lynn. It is probable, however, that the art of weaving was general over the whole county, for it appears that Norfolk was by far the wealthiest of the English counties at the time referred to. (Rogers, *Agriculture and Prices in England.*) The art of weaving was either brought into England, or at least improved, by the Flemings, between whom and the inhabitants of the eastern English counties close commercial relations subsisted. The fact of these relations will explain the political alliances between the English sovereigns and the weavers of Bruges, Liège, and Ghent.

Certain specimens of early English cloth may yet be seen. New College in Oxford still possesses the mitre case of the founder, a strong wooden box covered with leather, banded with iron, and lined with stout cloth; but the

wool is coarse and full of hairs, and the texture of the cloth is rude. The high market price of English wool was owing, doubtless, to the absence of such security on the Continent as was necessary for the raising of sheep. The greatest care was taken to secure, by means of a police [ULNAGE], that imported cloth should come up to the standard of length and breadth.

The chief mart of English and foreign cloth was Stourbridge fair, which was held in a field about two miles from Cambridge, and lasted about a month. This fair was to the mediæval Englishman as important as that of Novgorod or Leipsic to the Russian and German.

Woold. In Naval language, to strengthen a made or started spar, by winding tarred rope tightly round it at the weak or suspected place.

Woolsack. The seat of the Lord Chancellor, in the House of Lords, is said to be so called from its having originally been a large square bag of wool without back or arms. There can be no doubt, at all events, that the ancient name represents the great importance of the wool trade of the middle ages.

Wootz. A species of steel of excellent quality, imported from India, and of which it is believed that the celebrated Damascus sword blades were made. It is made by melting small pieces of wrought iron mixed with some twigs from a tree and covered by a green leaf in small crucibles luted close with clay; these crucibles are then built up in a pyramidal form in a furnace and exposed to a strong heat. The pieces of wootz are taken out after the crucibles have cooled, and are of the size of about half a hen's egg. To form a Damascus sword blade, each piece of wootz was drawn out under the hammer into a thin riband, and a bundle of these was then welded together. Woots has been known from a remote antiquity. It contains traces of silicium and aluminium.

Words (A.-Sax. wyrd; Ger. wort, from werden, *to become*). In Language, the names assigned to conceptions or phenomena. According to the realistic doctrine, words were things, and the existence of a word implied not merely the existence of a conception, but the existence of an object answering to that conception. This notion underlies the Aristotelian dictum *de omni et nullo* [LOGIC]; its practical effects are noticed in the articles PROPOSITION and SYLLOGISM. The analysis of LANGUAGE shows that all abstract terms, denoting intellectual or transcendental ideas, are derived by METAPHOR from words originally expressive only of animal or bodily sensations. The so-called UNIVERSALS are thus mere labels or tickets, for the more convenient arrangement of our observations of phenomena; and such a term as *humanity* is merely a name for all men collectively, and must not be taken as implying the existence of any abstract thing or essence existing out of or apart from all individual men. The same may be said of such words as Virtue, Justice, Truth, and other like terms. For the origin of names, the reader is referred to the articles ROOTS, POLYONYMY, and SYNONYMY; and for their influence in the formation of religious ideas, to THEOLOGY, VRITRA, WERE-WOLVES, WITCHCRAFT, &c.

Work (A.-Sax. weorc, Ger. werk, Gr. ἔργον). In Mechanics, the work performed by any force is measured by the product of the force into the space through which it is exerted. In Britain the *unit of work* is called the *foot-pound*, and is that which is performed in raising a pound weight, in opposition to gravity, to a height of one foot. The work required to raise five pounds to a height of ten feet, therefore, is fifty *foot-pounds*.

World (A.-Sax. werrold, Swed. verld). A name sometimes used to denote the earth, and sometimes the whole cosmos. The ancient myths on the origin of the world are noticed in the article THEOGONY, while the philosophical theories of the earliest philosophers on the same subject are sketched in the articles ELEATIC PHILOSOPHY, IONIAN PHILOSOPHY, and PYTHAGOREANS. All these theories, like the astronomical science of the Greeks, are deductive in character, and start with some arbitrary hypothesis with which observed phenomena must be made to harmonise. A summary of the results obtained by inductive observations of phenomena is given in Humboldt's *Cosmos*. For the physical systems of mediæval thinkers, see Hallam, *Middle Ages*, part ii. ch. iii.

Worm Bark. The bark of the *Andira inermis*, or *Cabbage bark tree*, of the West Indies. It is cathartic, emetic, and narcotic, in doses of from twenty to thirty grains. It is usually given in the form of decoction.

Worm Seed. The substance sold under this name, or that of *Semen contra*, consists of broken peduncles, mixed with the calyces and flower buds of some species of *Artemisia*, and is not the seed of *Artemisia Santonica*, as usually represented. Worm seed is imported from the Levant, and used as a vermifuge in doses from ten to thirty grains. This name is also applied to *Ambrina anthelmintica*, *Erysimum cheiranthoides*, *Artemisia Vahliana*, and *A. judaica*. [SANTONIN.]

Worm Tea. A preparation kept in the shops of the United States, and much used: it consists of spigelia root, savine, senna, and manna.

Wormia (after Olaus Wormius, a Danish naturalist). One of the species of this genus of *Dilleniaceæ*, *W. excelsa*, is a very large forest-tree, native of Java and the Malayan Peninsula, where it is called Kayu Sipur by the Malays, and is valued for its excellent timber, which bears some resemblance to oak.

Wormwood. The *Artemisia Absinthium*, a composite shrub, containing a peculiar bitter principle, called *Absinthine*, to which its medical virtues may be ascribed. Its infusion was formerly a favourite popular remedy for worms, but it is now disused. A liqueur flavoured by wormwood is in great repute in France, under the name of *Crême d'absinthe*.

Wort (A.-Sax. wyrt; Ger. wurz, *a herb*). A plant or herb. The word was formerly used in a general sense, but is now chiefly employed in compounds, as Spleenwort, Woundwort, Mugwort, &c.

Woulfe's Apparatus. A series of two or three necked bottles, connected by intermediate tubes, used in the chemical laboratory for impregnating water and other liquids with various gases or vapours. It is also a convenient form of apparatus for the generation of gases where the assistance of heat is not required.

Wound Balsam. The compound tincture of *Benzoin* of the *Pharmacopœia*, known also as *Friar's Balsam.*

Wourali or **Wourara.** The Woorari, Ourari, or Urari, an arrow-poison prepared by the South American Indians, from *Strychnos toxifera.* [OURALI; STRYCHNOS.]

Wrack (Fr. varech). The *Zostera marina*, a common weed of the sea, though not belonging to the sea-weed family (*Algæ*), is the Sea Wrack, or Grass Wrack. It has been referred to the *Naiadaceæ*, but is sometimes regarded as the type of an order *Zosteraceæ*. Its long grass-like leaves are collected for packing, and for stuffing mattresses, under the name of *Ulva marina*. The term *Wrack* is also applied to sea-weed generally when thrown ashore. This wrack is collected by farmers who cultivate coast land, and is used as a manure.

Wrangler. At Cambridge, those who attain the highest honours in the public mathematical examinations for the degree of bachelor of arts are so called. At the close of the last day of examination, those who have most distinguished themselves (to the number of thirty at least) are arranged in order of merit by the examiners, and divided into three classes: wranglers, senior optimes, and junior optimes. The first or senior wrangler is the most distinguished mathematician of his year. The name is probably derived from the public disputations in which candidates for degrees were formerly required to exhibit their powers.

Wrecks (A.-Sax. wræc, akin to Lat. frango, freg-i; Gr. ῥήγνυμι; Ger. brechen, *to break*). Goods cast up by the sea after a shipwreck, and left on land within the limits of some county. The goods so brought to land belong at common law to the king, or to the lord of the manor enjoying the franchise of wreck. It was ordained by Henry I. and Henry II. that such forfeiture should not take place if any man or beast escaped alive from the wreck; and we find in Bracton (Henry III.) that in his time if the goods could be known by marks to appertain to any owner, it was no wreck, even if no living creature escaped. The limitation of claims by the owner, by stat. West. 1 (3 Edw. I.), was within a year and a day. The Board of Trade now appoints receivers of wreck, who are to keep the goods a year; if not claimed within that time they go to the crown. (See Merchant Shipping Act of 1854, and amending Act.) Plundering wrecked vessels or goods stranded is felony. Goods cast overboard at sea, and not stranded, are divided into JETSAM, i.e. things sunk to the bottom; FLOTSAM, things found floating; and *ligsam*, things sunk, but fastened to a buoy or cork in order to be found again. These do not pass by the ordinary grant of wreck, but are expressly included in the statutory jurisdiction of the Board of Trade.

Wreckers. A name commonly applied to persons who make it their business to pillage shipwrecked vessels. In the Bahamas, the *wreckers* are vessels licensed by government to succour ships in distress, and they are allowed a salvage on the property recovered by them.

Wrestling (A.-Sax. wræstlian, *to struggle*). This practice of wrestling answers to the Greek πάλη, in which the wrestler had to throw his adversary either by swinging him round or tripping him up. [TEUTONIC.]

Wrightia (after Dr. W. Wright, a Scotch physician). A genus of *Apocynaceæ*, consisting of shrubs, or small, sometimes scandent and aërial rooting trees, confined to the eastern hemisphere, ranging from Silhet and Nepal to Western Australia. An inferior kind of indigo is prepared from the leaves of *W. tinctoria* in some parts of Southern India, and called Pala Indigo, from Pala or Palay, the Tamil name for this and some allied milky trees. The wood of the Palay is beautifully white, close-grained and ivory-like, and is commonly used in India for making toys. It is well suited for turning, carving, and inlaying, and has been tried for engraving as a substitute for boxwood, but found unsuitable. The wood of *W. antidysenterica* has also been made the subject of a similar experiment without success. It is very hard in centre, and is used in India for posts and rice-beaters. The bark is the Conessi-bark of the *Materia Medica*, and is valued as a tonic and febrifuge, and as a remedy for dysentery. The oat-like seeds also are reputed to possess valuable medicinal properties.

Wrist Drop. A disease to which compositors are liable, caused by using new type, which cuts the skin of the thumb and fingers. Lead poison enters at the abraded places, and paralysis of the wrist is the result. It may be cured by soaking the hand in a solution of potassium, and eliminating the lead.

Writ (A.-Sax. writan, to *engrave*). In Law, a precept in writing under seal, in the name of the king, judge, or any other person having jurisdiction in the particular subject-matter, and directed to some public officer or private person, requiring him to do something in relation to a suit or action, or otherwise.

Writers to the Signet. A society of lawyers in Scotland, equivalent to the highest class of attorneys in England. [SIGNET.]

Writing. [ALPHABET; CUNEIFORM LETTERS; PAPER.]

Wryneck. A permanent inclination of the head towards one of the shoulders, not necessarily connected with distorted vertebræ, but arising mostly from a contraction of the

sterno-cleido-mastoideus muscle. This is often a spasmodic affection, and connected with nervous lesion.

WRYNECK. The *Yunx torquilla*, a common English scansorial bird, observed in spring.

Wulfenite. A name for the native molybdate of lead, after the Austrian metallurgist, Wulfen. It occurs crystallised and massive, generally of an orange or wax-yellow colour passing into grey, green, or brown, in Dauphiny, Carinthia, Hungary, Saxony, &c.

Wuotan. [WODEN.]

Wyvern. In Heraldry, an imaginary animal resembling a flying serpent.

X

X. A letter borrowed from the Greek, and used chiefly in words derived from that language. As a Roman numeral, it denotes 10.

Xanthein (Gr. ξανθός, *yellow*). The yellow colouring matter of flowers.

Xanthic Acid (Gr. ξανθός). *Sulphocarbethylic acid.* An acid composed of sulphur, carbon, hydrogen, and oxygen, and obtained in combination with potassa by agitating bisulphuret of carbon mixed with solution of pure potassa in strong alcohol. Its compounds are of a yellow colour, whence its name. Its atomic composition has been represented as $HO,C_6H_5OS_4$.

Xanthic Oxide. A yellow substance found by Dr. Marcet in a urinary calculus; its solution in nitric acid, when evaporated to dryness, left a bright lemon-coloured residue. Its composition is $C_{10}H_4N_4O_4$.

Xanthin (Gr. ξανθός). The yellow colouring principle of madder.

Xanthite (Gr. ξανθός). A variety of Idocrase found in small rounded grains or imperfect crystals of a yellow or greyish colour, at Amity in New York: its principal constituents are silicate of alumina and silicate of lime.

Xanthochymus (Gr. ξανθός, and χυμός, *juice*). This genus of arboreous *Clusiaceæ*, which is named in allusion to the yellow resinous juice which exudes from their trunks, consists of three tropical Asiatic species. *X. ovalifolia* is confined to Ceylon, and was at one time supposed to be the tree which afforded the Gamboge of that island; but this is now known to be the produce of *Garcinia Morella*, the juice of *X. ovalifolia* being valueless. *X. pictorius*, a native of the mountains of Northern India, and *X. dulcis*, found in the islands of the Indian Archipelago, both yield edible pleasant-tasted fruits about as large as apricots, of a beautiful bright shining yellow colour, of a nearly globular form.

Xanthocone (Gr. ξανθός, and κόνις, *dust*). An arsenio-sulphide of silver found in very thin six-sided tabular crystals, but generally in small crystalline kidney-form masses at the Himmelfürst Mine, near Freiberg, in Saxony. It is of a dull-red or clove-brown colour, but affords a yellow powder (whence the name).

Xanthophyll (Gr. ξανθός, and φύλλον, *a leaf*). The yellow autumnal colouring matter of leaves.

Xanthophyllite. A variety of Clintonite found in implanted globules and in foliated crystalline individuals in the talcose slate of the Schischimskian Mountains of the Ural. It is a combination of silicate of alumina with silicate of magnesia.

Xanthopicrin or **Xanthopicrite** (Gr. ξανθός, and πικρός, *bitter*). A crystalline bitter principle contained in the bark of the *Xanthoxylon caribæum*, which is used in the Antilles as a febrifuge. It forms yellow acicular crystals, insoluble in ether, but readily soluble in alcohol, and sparingly in water.

Xanthoprotein (a word coined from Gr. ξανθός, and πρωτεῖον, *the chief rank*). A yellow acid substance formed by the action of nitric acid upon fibrine.

Xanthorhamnin (Gr. ξανθός, and ῥάμνος, *a prickly shrub*). A yellow substance extracted from the berries of *Rhamnus tinctoria*, the *Persian berries* of commerce. It contains $C_{23}H_{12}O_{14}$.

Xanthorrhiza (Gr. ξανθός, and ῥίζα, *a root*). A genus of *Ranunculaceæ*, represented by an undershrub, *X. apiifolia*, inhabiting the Southern States of North America. The name is given to this plant from its long roots and rootstocks, which are of a bright-yellow colour; whence also it is commonly called Yellow-root in the United States. Its inner bark wood and pith are also of the same colour. The whole plant was formerly employed by the American aborigines for dyeing yellow; and the American physicians of the present day use it medicinally as a tonic, all parts of it having a purely and intensely bitter taste.

Xanthorrhœa (Gr. ξανθός, and ῥέω, *to flow*). The genus of *Liliaceæ* to which belong the Black-boy or Grass Gum trees of the Australian colonies, most of the species of which have thick trunks like those of palms, covered with a dense coating formed of the persistent bases of old leaves glued together by the yellow or red resin with which these plants abound, and usually burnt and blackened outside by bush-fires. Their leaves are long, wiry, and grass like, and are borne in a dense tuft at the top of the stem, and hang down gracefully all round it; their long flower-stalks rising out of the centre, and sometimes growing as high as fifteen or twenty feet, bearing at the top a dense cylindrical flower-spike.

The tall-growing species, *X. arborea*, *X. hastilis*, &c. form a conspicuous feature in

some Australian landscapes; and when denuded of leaves have been compared to or even mistaken for black men holding spears, hence their common colonial name. Their leaves afford good fodder for cattle, while the natives eat the tender white centre of the top of the stem. Two kinds of fragrant resin —one of a yellow colour, called Botany Bay or Acaroid resin, and the other red like Dragon's Blood, and called Black-boy Gum—are obtained from them.

Xanthorthite (Gr. ξανθός, and ὀρθός, *straight*). A yellowish variety of Orthite from Eriksberg and Kullberg in Sweden.

Xanthosiderite (Gr. ξανθός, and σίδηρος, *iron*) A variety of Brown Iron-ore, occurring in yellowish-brown concentric and radiating aggregations of fine fibres with a silky lustre, at Ilmenau in the Harz.

Xanthoxylaceæ (Xanthoxylon, one of the genera). A natural order of hypogynous Exogens, closely allied to *Rutaceæ*, of which some botanists have regarded them as a section. They are distinguished from *Rutaceæ* chiefly by having unisexual flowers, with small spreading petals, a lobed ovary with two ovules in each cell, and lateral or basal styles often united at the top only, the fruit usually separating into distinct cocci varying from two to five in number.

The type of the order is *Xanthoxylon* (Gr. ξανθός, *yellow*, and ξύλον, *wood*), a rather extensive genus, having representatives in most of the tropical countries of the world, and in some parts of the temperate regions—one reaching as far north as Canada in the western, and several as far as Japan in the eastern hemisphere. The species differ considerably in appearance, some being large trees, while others are erect or climbing shrubs. The fruits of most of the species have an aromatic pungent taste like pepper. Those of *X. piperitum*, a Japanese species, are called Japan-pepper; and those of *X. hastile* are the Tej-bul of Northern India, where they are used for intoxicating fish. The popular name of Toothache-tree is applied to several American species (especially *X. fraxineum*), their bark and fruits being employed as a remedy for toothache. *X. caribæum*, a West Indian, and *X. nitidum*, a Chinese species, are reputed to be febrifugal; while the young prickly stems of *X. Clava-Herculis* are commonly made into walking-sticks in the West Indies.

Xebec. A small three-masted lateen-sailed vessel, constructed for conveying merchandise or stores: it is found chiefly in the Mediterranean and on the coasts of Spain and Portugal.

Xenelasia (Gr. ξενηλασία, *the expulsion of strangers*). An ordinance attributed to Lycurgus, which forbade strangers to reside in Sparta without permission, and empowered magistrates to expel strangers if they saw fit to do so. Pericles reproaches the Spartans for this, as being grounded on a fear of imparting dangerous knowledge to an enemy. (Thuc. ii. 39): it more probably arose from a desire to repress any liking for novelties or foreign fashions. (Xenophon, *De Rep. Laced.* xiv. 4.)

Xenolite (Gr. ξένος, and λίθος, *stone*). A fibrous kind of Sillimanite, found at Peterhoff, in Finland. It is a silicate of alumina, resembling Kyanite, of which it was formerly supposed to be a variety.

Xenotime (Gr. ξένος, and τιμή, *honour*). A phosphate of yttria, found at Ytterby in Sweden. The name has reference to the mistake which was made in supposing phosphate of yttria to be a new metal, to which the name Thorium was given, but which is now assigned to the metal discovered in the mineral called Thorite.

Xeque. The Spanish form of the Arabic Sheikh.

Xeringue. A South American name for the caoutchouc-yielding *Siphonia* and *Micrandra*.

Xerophagia (Gr. from ξηρός, *dry*, and φάγω, *I eat*). In Ecclesiastical Antiquities, a name given to the rigorous practice of certain fasts, during which nothing was consumed but bread with salt, and water. It was particular observed in Holy Week.

Ximenia (after Francis Ximenes, a Spanish writer on medicinal plants). The three or four species of this genus of *Olacaceæ* are either large shrubs or small trees, frequently armed with spines. *X. americana* produces oblong yellow fruits about an inch in length, which are eaten by the natives in various parts of the tropics, and which have an acid-sweet aromatic taste, with some degree of austerity. Its flowers are very fragrant, smelling something like cloves; and its wood is also odoriferous, and is used in India as a substitute for sandalwood, but it is obtainable only in pieces of small size. *X. elliptica*, a native of the Feejees and other islands of the Pacific Ocean, bears round orange-coloured fruits, of which the natives are very fond, though they are rather tart: before they are ripe they possess a powerful odour of essential oil of almonds. It also produces an extremely hard wood.

Xiphirhynchs (Gr. ξίφος, *a sword*, and ῥύγχος, *a snout*). The name given by Latreille to a family of Acanthopterygious fishes, of which the sword-fish (*Xiphias*) is the type.

Xiphosures (Gr. ξίφος, and οὐρά, *a tail*). A name of a tribe of Crustaceans, comprehending those in which the body terminates posteriorly in a long, hard, sword-shaped appendage.

Xylite (Gr. ξύλον, *wood*, and λίθος, *stone*). An asbestiform mineral from the Ural, allied to Xylotile in composition and structure, as well as in its brown colour.

Xylochlore (Gr. ξύλον, and χλωρός, *green*). A mineral closely resembling Apophyllite, and found in olive-green crystals in Iceland.

Xylography (Gr. ξυλογραφέω, *to write on wood*). Wood engraving. [Engraving.]

Xyloidin (Gr. ξύλον). A white granular substance, formed by the action of nitric acid upon starch, and upon certain modifications of

lignin: it is related to Schönbein's *gun cotton*. [PYROXYLINE.]

Xylol. A colourless liquid hydrocarbon, occurring among the oils contained in crude wood-spirit.

Xylophagans (Gr. ξυλοφάγος, *eating wood*). The name of a tribe of Coleopterous insects, comprehending those of which the larvæ devour the wood of trees in which they are developed; also applied to a family of Dipterous insects, the larvæ of which have similarly destructive habits.

Xylophilans (Gr. ξύλον, and φιλέω, *I love*). The name of a tribe of beetles, consisting of those which live on decayed wood.

Xylophylla (Gr. ξύλον, *wood*, and φύλλον, *a leaf*). A genus of *Euphorbiaceæ* or (as some regard it) a section of *Phyllanthus*, consisting of shrubs, without leaves, but having the branches flattened out and leaf-like, and bearing the flowers in tufts in the notches of their margin. The plants are natives of the West Indies and other tropical countries, and receive their generic name from the singular appearance of their leaf-like branches.

Xylopia. A genus of *Anonaceæ*, consisting of trees or shrubs indigenous to Brazil and other warm districts of South America, the West Indies, &c.

The species are noted for the bitterness of their wood, and the aromatic properties of their fruit and seeds. *X. frutescens*, a native of Cayenne, yields seeds which are eaten by the natives instead of spices. *X. grandiflora*, a Brazilian species, is sought for on account of its carminative fruits, which are also esteemed for their febrifugal properties. The Bitter-wood of the West Indies is the wood of *X. glabra*. Sugar placed in hogsheads made of this wood becomes so highly impregnated with the bitter flavour as to be useless, and even cockroaches will not touch the casks. The bark and fruits are said to taste like orange-seeds. *X. aromatica*, a native of South America, furnishes fruits used by the natives in place of pepper—hence the fruits are sometimes spoken of under the name of Ethiopian Pepper. *X. sericea*, a native of Brazil, also supplies aromatic pepper-like berries. The tough bark of this tree, as of *X. frutescens*, is in esteem, owing to the excellent cordage manufactured from its fibres. The fruits of *X. undulata* are employed in the Sandwich Islands in place of spice. Some of the Javanese spices, according to Blume, are not altogether free from noxious properties, for if too often or too largely partaken of, they give rise to vertigo and hæmorrhage.

Xyloretine (Gr. ξύλον, and ῥητίνη, *resin*). A crystalline resinous substance, found in certain varieties of turf.

Xylotile (Gr. ξύλον, and τίλος, *flock* or *down*). A delicately fibrous variety of Chrysotile, of various shades of wood-brown, and green, from Sterzing in the Tyrol.

Xylotroges (Gr. ξύλον, and τρώγω, *I gnaw*). The name of a tribe of Serricorn beetles, comprehending those which perforate timber.

Xyridaceæ (Xyris, one of the genera). A small natural order of Endogens, consisting of rush-like or sedge-like herbs, with fibrous roots, and long narrow radical leaves, the yellow flowers growing in heads which are enclosed in imbricate scales, at the top of leafless scapes. The perianth consists of three outer segments, of which one is more petal-like than the others, or of that one only, and either two or three inner petal-like segments. There are three stamens. The ovary is free, with three parietal placentas; and the capsule opens in three valves, containing numerous small albuminous seeds. The species are almost all tropical, dispersed over both the New and Old Worlds.

Xyst or **Xystos** (Gr. ξυστός, from ξύω, *I polish*). In Ancient Architecture, an open, or sometimes covered court, of great length in proportion to its width, with porticoes on three sides, used for the exercises of wrestling, running, &c.

Y

Y. A letter borrowed from the Greek υ. It is considered a consonant at the beginning, and a vowel in every other place, in English words. As a vowel, it has exactly the sound of *i*, being short or long according to its position. It is one of the letters represented by the Greek DIGAMMA.

Y Shaft of an Engine. The shaft for moving the valve, so called because in the old atmospheric engines the forked lever for giving motion to the valve or regulator was made in the form of the letter Y. The name is sometimes corrupted into *weigh shaft*.

Yacca. *Podocarpus coriacea*, which yields an ornamental wood used in the West Indies for cabinet-work under the name of Yacca-wood.

Yacht (Dutch jagt, Ger. jacht). A decked pleasure vessel. Yachts belonging to clubs recognised by the Admiralty have many of the privileges of the royal navy. This is an excellent arrangement, as they are an admirable nursery for daring seamen, and that without expense to the state. There are about 1,300 yachts in the several clubs of the United Kingdom, the average being about 30 tons.

Yagers or **Jägers** (Ger. *hunters*). Light infantry armed with rifles (*chasseurs, riflemen*). In the Prussian service, the yagers form a distinct corps with peculiar discipline; in that of Austria, light infantry generally from the mountain districts. In Germany the term *jäger* is applied to a peculiar species of higher servant attached to the families of the aristocracy.

Yam. The name applied to the fleshy edible roots of different species of *Dioscorea*, which are much cultivated as food in tropical countries. The common Yam is *Dioscorea sativa*. [DIOSCOREACEÆ.]

Yankee. The popular name for the New Englanders in America, and among English people indiscriminately applied to all inhabitants of the United States. Many ridiculous etymologies have been assigned for this word, which appears to be only a corruption of the word *English* by the Indians of North America.

Yanolite. A Mineralogical synonym of AXINITE.

Yapon. The South Sea Tea, *Ilex vomitoria*.

Yard (A.-Sax. geard, gyrd). The British standard measure of length. In early times the yard and ell appear to have been synonymous. The later ell, containing five quarters of a yard, was an introduction from the Low Countries. The imperial yard was defined to be 'the straight line or distance between the centres of two points in the gold studs in the straight brass rod now in the custody of the Clerk of the House of Commons.' This standard was destroyed in the fire which consumed the houses of parliament. With a view to recovering the measure, it was declared, that when compared with a pendulum vibrating seconds of mean time in the latitude of London, in a vacuum at the level of the sea, it would be in the ratio of 36 inches to 39 inches and $\frac{1393}{10000}$ of an inch. This calculation is, however, said to be inexact. The proportion of the yard to the mètre is as 3 to 3·280916.

The *yard* or virgate is also an ancient land measure, the exact quantity of which is not perhaps recoverable. It was probably determined by the quality more than by the quantity of land. It continued in use as late at least as the middle of the last century. [MEASURES.]

YARD. A spar suspended across a mast, by a rope called the *halliards* and *lifts*, for the purpose of extending a sail. A yard is called a *square yard* when hung horizontally by the middle: such a yard is adjusted to the wind by braces.

Yard-arm. In Naval language, the extremity of the yard. *Yard-arm and yard-arm* is a term descriptive of two ships engaging each other as close as possible.

Yarn. The threads of fibre of which the strands are composed which make a rope.

Yarrow (A.-Sax. gearwe, Span. yaro). The *Achillea millefolium* of botanists, a common native perennial weed of the Composite order, remarkable for its finely cut leaves, its large corymb, of small white flower-heads, and its strong aromatic odour. It yields a peculiar bitter principle. [ACHILLEINE.]

Yaruri. A Demerara name for the Paddle-wood, the strong but light and elastic timber of *Aspidosperma excelsum*.

Yaw. The Sea term for temporary deviation from a direct course.

Yawl. A decked boat carrying two masts, of which one is at the extreme stern. The rig is usually like a lugger.

Yaws. A disease in which eruptions form upon the skin somewhat resembling a raspberry. [FRAMBŒSIA.]

Year (A.-Sax. gear, Ger. jahr). A period of time determined by the revolution of the earth in its orbit, and embracing the four seasons. The year is either *astronomical* or *civil*.

The astronomical year is determined by astronomical observations, and is of different kinds, according to the celestial body or the point of the heavens to which the earth's revolution is referred. When the earth's motion in its orbit is referred to an immovable point in the heavens (to a fixed star, for example), the time of revolution is that which elapses from the instant at which the star, the sun, and the earth are in a certain relative position, till the earth returns again into the same position with regard to the sun and the star. This interval is called the *sidereal year*. But when the earth's motion is referred to a point of the ecliptic, as one of the equinoctial points or the tropics, the time of revolution is that in which the earth returns to that point, and is called the *equinoctial* or *tropical* or *solar year*. On account of the precession of the equinoxes [PRECESSION], the equinoctial and solstitial points, in reference to the fixed stars, have a retrograde motion on the ecliptic, in consequence of which the earth returns to one of these points in a shorter time than it returns to the same fixed star.

The length of the *sidereal year* is 365·2563612 mean solar days; or 365 d. 6 h. 9 m. 9·6 s.

The length of the *equinoctial* or *tropical year* is 365·2422414 mean solar days, or 365 d. 5 h. 48 m. 49·7 s. (Bailey's *Tables*, p. 16.)

The difference is 20 minutes 19·9 seconds of mean solar time, being the time in which the earth describes in its orbit an arc of 50·1″, the annual precession of the equinoxes. [EARTH.]

The earth's motion may also be reckoned by the time in which a revolution is completed with respect to the line of the *apsides* or the line of the *nodes*. In these cases the times of revolution may be called respectively the *anomalistic year* and the *nodical year*: the former term is sometimes met with.

The *civil year* is the year of the calendar. As it is always supposed to begin with the beginning of a day, the civil year contains a whole number of days; and hence, in order that the seasons may always correspond with the same parts of the year, it is necessary from time to time to vary the length of the year, or to intercalate a day when the fractional parts

neglected have accumulated to a whole day. The ancient Egyptian year consisted invariably of 365 days, and hence was called a *vague* or *erratic* year, because the first day of the year in the course of 1,460 years *wandered* as it were over all the seasons.

The *Julian year*, which is frequently employed in chronological reckoning, consists of 365¼ days. Julius Cæsar, advised by the astronomer Sosigenes, ordered that the civil year should consist of 365 days for three successive years, and that the fourth year should contain 366 days. This practice of intercalating a day every fourth year, has been adopted in all European countries, with the modification introduced by the Gregorian calendar. The mean Julian year is longer than the true tropical year by 11 m. 10·3 s., a difference which amounts to a whole day in about 120 years. The years which contain 365 days are called *common years*; those which contain 366 days are called *leap years*. [LEAP YEAR.]

According to the regulations of the Gregorian calendar, the intercalations are omitted in the years which end centuries, excepting when the number of the year is divisible by 4, after leaving out the two zeros. Thus the years 1700, 1800, 1900, which would be leap years in the Julian calendar, are common years in the Gregorian; but 1600 and 2000 are leap years in both calendars. [CALENDAR.] The mean length of the Gregorian year is 365 d. 5 h. 49 m. 12 s., exceeding the true tropical year by 22·38 s., which amounts to a whole day only in about 3,866 years.

The civil or legal year, in England, formerly commenced on March 25, the day of the Annunciation, though the historical year began on January 1, the day of the Circumcision. Between these two epochs it was usual to date the year both ways, as 1745–6, or $174\frac{5}{6}$. By the Act of Parliament for the alteration of the style in 1751, the beginning of the year was transferred to January 1. It is frequently necessary to keep this circumstance in mind in referring to old dates.

The fraction by which the tropical years exceed 365 days is ·2422414; and the series of approximating vulgar fractions alternately greater and less than this quantity is—

$$\frac{1}{4}, \frac{7}{29}, \frac{8}{33}, \frac{39}{161}, \frac{281}{1160}, \text{\&c.}$$

The fractions in this series indicate the intercalations by which the coincidence between the civil and solar year may be restored to any degree of exactness. The third, $\frac{8}{33}$, offers a very convenient mode of intercalation which would preserve the coincidence with great accuracy. It requires eight intercalations to be made in thirty-three years, i. e. one at the end of four years seven times in succession, and the eighth at the end of the fifth year. The mean length of the civil year would by this arrangement differ in excess from the solar year only by 15·38 seconds, while the Gregorian year is too long by 22·38 seconds. In a period of thirty-four years it therefore produces a nearer coincidence between the civil and solar years than the Gregorian method does in 400 years; and by reason of its shortness it also confines the evagations of the mean equinox from the astronomical within much narrower limits. The modern Persians are said, but not on very good authority, to intercalate in this manner. (Delambre, *Astronomie Moderne*, tom. 1.) [CALENDAR.]

Lunar Year.—Though the return of the seasons obviously depends on the motion of the sun, or rather of the earth in its orbit, some nations have chosen to regulate their civil year by the motions of the moon; and many others have formed luni-solar years, by combining periods determined by the revolutions of both bodies. The proper lunar year consists of twelve lunar months or lunations, and consequently contains only 354 days: its commencement, therefore, anticipates that of the solar year by upwards of eleven days, and passes through the whole circle of the seasons in about 34 lunar years. The inconvenience attending this circumstance has been so universally perceived, that, excepting the modern Jews and Mohammedans, almost all nations which have regulated their months by the moon have employed some method of intercalation for the purpose of retaining the beginning of the year at nearly the same place in the seasons. These methods are founded on certain luni-solar periods or cycles, which were established in the most ancient times, and which, with other relics of a barbarous age, are still preserved in our ecclesiastical calendars. [CALENDAR; CHRONOLOGY; CYCLE.]

Year to Year, Tenancy from. This is the common mode of letting houses or lands when occupied for more than a year without any definite term of years being granted. It is determinable at the option of either party on half a year's notice, but the notice must be given so as to expire at the end of a current year of the tenancy. Thus, as soon as the first half year of such a holding has expired, the tenancy becomes an absolute one for two years at least from the date of its commencement. When a house or land is occupied under an annual rent, and nothing is stated as to the duration of the occupancy, the law will assume that the tenancy was intended to be one from year to year.

Yeast (A.-Sax. gist, Ger. gäscht). The substance produced during the vinous fermentation of vegetable juices and decoctions, rising partly to the surface in the form of a frothy, flocculent, and somewhat viscid matter, insoluble in water and alcohol, and gradually putrefying in a warm atmosphere. It excites fermentation, and accelerates the process when added to saccharine and mucilaginous liquors. The nature of yeast, and the part which it plays in the process of vinous fermentation, have given rise to much theoretical discussion, and to many valuable investigations. (Pasteur, in *Annales de Chimie et de Physique*, third series, lviii. p. 323.) [BARM; FERMENTATION.]

Yeast Plant. It has been long known (observes Mr. Berkeley in the *Treasury of Botany*) 'that the particles of which yeast is composed germinate, and are multiplied with extraordinary rapidity when placed in a solution of sugar kept at a proper temperature. It was therefore at once allowed that the substance was organised, whether belonging to the animal or vegetable kingdom; and while some pronounced it an alga, others as confidently asserted that it was a fungus. Dr. Hassall and others observed that a particular mould grew pretty uniformly on a solution of malt; but we believe that Mr. Hoffmann, in union with Mr. Berkeley, first watched the growth of single yeast-globules in a drop of water surrounded by air enclosed in a glass cell, and ascertained that a *Penicillium* and a *Mucor* grew immediately from the globules. They were also convinced that these were not the only moulds to which the yeast-globules gave rise. It was clear, then, that yeast consists of a mixture of different moulds in a peculiar condition due to their developement in a fluid, and that when a fit opportunity offers, these globules are capable of being developed into their ordinary form. The globules, however, preserve their character without developing their perfect forms when the fluid in which they float is drained away, and in this condition the mass is called *German yeast*, a substance largely imported into this country, and both on account of its freedom from the bitter principle of hops, as well as from some peculiarities in its action on fermentable substances, often preferred to ordinary fluid yeast. It is a singular fact respecting yeast in this condition, that a sudden fall from a great height will sometimes completely destroy its power of vegetating.

'Yeast is of very different qualities, according to the nature of the liquor in which it is generated; and though there is little difference, if any, to the naked eye, the yeast-merchants distinguish several varieties, which, according to their respective energy and activity, are employed for different purposes. It has not yet been ascertained whether these different varieties are composed of the germs of different species of *Fungi*, or of the same species in different proportions. It is often said that yeast works by catalysis, but this is merely the substitution of a hard word for the naked fact that yeast promotes fermentation. There is no doubt, however, that it acts partly by presenting a large surface over which the fluid is spread, and thus favouring the disengagement of the carbonic acid gas, formed in the process of fermentation, exactly as that gas is set free when a lump of sugar or a piece of bread-crumb is placed in a glass of effervescent wine which has apparently previously parted with all the gas which it contained. It is moreover conjectured, that as chemical change always takes place when there is an interchange of two fluids of different densities separated by a membrane, the decomposition of a fermentable fluid containing yeast is favoured by this interchange, which is known to chemists and physiologists under the names of *endosmose* and *exosmose*.

'Substances which are hostile to the growth of fungi, generally, are hostile to fermentation. Hence a mixture of sulphites of soda, or the ignition of sulphur, are used to arrest the process where it is necessary.'

Yellow (A.-Sax. gealew, Ger. gelb, Lat. gilvus). In Painting, a colour of golden hue, and of many varieties. It is one of the seven so-called primary colours, and is complementary to blue, with which it forms white. [Colour; Light.]

Yellow Berries. The dried unripe berries of *Rhamnus infectorius*, imported in large quantities from the South of Europe and the Levant for the use of dyers.

Yellow Copper-ore. [Copper Pyrites.]

Yellow Earth or **Yellow Iron-ochre.** A mixture of Limonite (hydrated peroxide of iron) with hydrated silicate of alumina, found at Pary's mine in Anglesea, in the Forest of Dean in Gloucestershire, France, Bavaria, the Harz, and elsewhere. It is sometimes used as a coarse yellow pigment, and is stated by Bunsen to be a valuable antidote to the poison of arsenic. [Yellow Ochre.]

Yellow Fever. This disease is described under two forms, one being a bilious fever, of malarious origin, in which the remissions are so connected that the disease rather resembles a continued fever. The skin becomes yellow during its progress. Intense heat assists much in producing this fever wherever marshy lands exist.

The other form, or the specific yellow fever, is of continuous type, and is considered contagious. It is attended by yellowness of skin, delirium, suppression of urine, black vomit, black dejections, and small, thready, intermitting pulse. This disease becomes endemic in low sea-coast districts, rarely occurring at an elevation more than 2,500 feet above the sea level. It has been stated, however, that it once prevailed in Jamaica at a height of 4,000 feet above the sea. Some writers regard the two forms of fever here described as being essentially the same, and only varying in the degree of malignancy.

Yellow Lead-ore. [Wulfenite.]

Yellow Mineral Resin. [Amber.]

Yellow Ochre. An earthy variety of Brown Iron-ore, which occurs in amorphous and earthy masses, of a dull yellow colour and streak, in the Forest of Dean in Gloucestershire, France, Bavaria, &c. It leaves a yellow trace when drawn across paper, and is used as a pigment. [Yellow Earth.]

Yellow Orpiment. Yellow arsenic or sulphuretted oxide of zinc, of a beautiful bright and pure yellow colour, used as a pigment. In its native state it is used under the name of *Zarnic* or *Zarnich*, varying in colour from warm yellow to greenish yellow. Orpiment in all its varieties, as a colour, is subject to change and to be changed by all pigments containing oxygen; and if used must be employed alone.

Much of the artificial Orpiment is only a glassy variety of arsenious acid, coloured with a variable proportion of yellow sulphide of arsenic, and is of no definite composition. It is produced by subliming arsenious acid and sulphur.

Yellow Tellurium. [SYLVANITE.]

Yenite. A name given to LIÉVRITE in commemoration of the battle of Jena.

Yeoman (A.-Sax. gemæne, Ger. gemein, *common*). Camden ranks yeomen as the next class to the gentlemen, and calls them *ingenui*. The name seems to have been generally appropriated in the middle ages to small freeholders below the rank of esquire. In several departments of the royal household, there are subordinate officials, styled *yeomen*.

YEOMAN. A seaman appointed to certain duties, as to attend to the storerooms.

Yeomanry Cavalry. A denomination given to those troops of horse which were embodied during the revolutionary wars of France, and afterwards among the gentlemen and yeomen of this country. There are at present (1867) 48 corps, comprising 264 troops, and forming a total of 14,268 of all ranks. Arms and ammunition are provided by the War Office, and there is an allowance of 2*l*. per man per annum; each man has to provide his own horse. The yeomanry are volunteers, but are liable to be called out in aid of the civil power in case of riot at any time; and in case of actual invasion or appearance of an enemy on the coast, or during a rebellion, they may be assembled for actual service; they are then subject to the Mutiny Act and Articles of War, and may be called on to serve in any part of Great Britain. [VOLUNTEERS.]

Yeomen of the Guard. [GUARD, YEOMEN OF THE.]

Yew. [TAXUS.]

Yezdigird, Era of. [ÆRA.]

Yezidis. [JEZIDS.]

Ynca. [INCA.]

Yoke (Ger. joch, Fr. joug, Lat. jugum, Gr. ζυγόν, *that which joins two things together*). A piece of wood or light frame of two arms, placed over the head of a boat's rudder instead of a tiller, and having two lines (*yoke lines*), by pulling on which the boat is steered. It is the most convenient arrangement in a narrow boat.

Yoni. The Hindu name for the female power in nature. The Yoni is the special emblem of Vishnu. It is exhibited in the form of a vesica, and is the boat-shaped vessel of which Iswarra is the lord, reproduced in the symbol spoken of by Tacitus as 'signum in modum liburnæ figuratum,' as well as in the ship over which the PEPLUS was carried in the Panathenaic procession. Ornaments in the shape of a complete or imperfect vesica have been popular in all countries as preservatives against dangers, especially from evil spirits; hence the practice of nailing up horseshoes on walls by way of protection against unknown perils, and of throwing a shoe after a newly-married pair by way of securing good luck. The name Yoni belongs to the root *jan*: for cognate words from the same source, see LANGUAGE. [LINGA; MYSTERIES; PHALLUS; SACTI.]

Ypoleime (Gr. ὑπόλειμμα, *a remnant*). [PHOSPHOROCHALCITE.]

Ytterbite. A Mineralogical synonym of Gadolinite, after one of its localities, Ytterby in Sweden.

Yttria Spar. [XENOTIME.]

Yttrium. The metallic base of an earth, discovered in 1794 by Gadolin in a mineral found at Ytterby in Sweden, whence it was called Yttria. The metal was first obtained by Wöhler in 1828: it is of a dark grey colour, and brittle. Very little is known of yttria or its salts. According to Mosander, three bases have been confounded under the name of yttria, two of which he distinguishes as ERBIA and TERBIA.

Yttro-Columbite. [YTTRO-TANTALITE.]

Yttro-Ilmenite. [SAMARSKITE.]

Yttrocerite. A native sesquifluoride of cerium, with fluoride of yttrium and fluoride of calcium (Fluor-spar), from Finbo and Broddbo in Sweden.

Yttrotantalite. A mineral from Ytterby, in Sweden, and the Ilmen Mountains in the Ural; composed chiefly of Yttria and Tantalum.

Yu. The Chinese name for Jade or NEPHRITE.

Yucca (Yuca, its name in St. Domingo). A genus of *Liliaceæ*, sometimes assuming an arborescent habit, producing a crown of linear-lanceolate more or less rigid leaves, and from the centre of each crown a tall erect panicle of showy whitish flowers. They are chiefly found in the Southern States of America and in Mexico, one or two extending to tropical America. They are very handsome garden plants, most of them nearly or quite hardy. In *Y. gloriosa*, one of the stateliest of the species, the crown of leaves becomes elevated on a stout stem, and the panicle is three feet or more in length, branching out on every side. In some, as *Y. filamentosa*, the leaves give off from their margin thread-like bodies, which hang loosely; and in one tender species, *A. schidigera*, these bodies are so large and broad as to resemble carpenters' shavings. The leaves, treated like hemp and flax, afford a fibre which may be used in the manufacture of cloth or cordage; and the macerated stems deposit a feculent matter, from which starch may be obtained. At Carthagena a starch or glue of this kind is made from the stem of *Y. gloriosa*.

Yugs or **Yogues.** Hindu eras or periods, four in number, and extending over millions of years. [SOTHIAC PERIOD; TABULATION OF CHRONOLOGY.]

Yule. The common Scottish name for Christmas. It appears to be a very ancient Celtic word. In Welsh, wyl or gywl signifies a holiday; whence also the old phrase *Gule of August*, the first day of August, or fast of St. Peter ad Vincula, for which various absurd

etymologies have been found. Possibly the old French word *Noël* for Christmas (used also generally as a popular cry of rejoicing) has the same original. (*Archæol.* vol. ii.) Some, however, derive yule from a supposed primitive word, connected with the idea of revolution or *wheel*; while Mallet (*Northern Antiquities* ii. 68) traces it to hiaul and houl (Lat. sol, Gr. ἥλιος), the word for *sun* in the dialects of Brittany and Cornwall. The term on the last supposition refers to the winter solstice. (Brand's *Popular Antiq.* vol. i. p. 346.)

Z

Z. The last letter in the alphabets of all the modern languages, usually regarded as a double consonant, from its having the sound in some languages of *ts* or *ds*. Like the letter *x*, it begins no word originally English; and Dr. Johnson has remarked, that although it is found in the Saxon alphabets, set down by grammarians, it is read in no word originally Teutonic.

Zachun. A fixed oil, expressed from the seeds of *Balanites ægyptiaca*.

Zaffre. This word is applied to the residues obtained by roasting native arsenides of nickel and cobalt, mixed with a certain proportion of silicious sand. The roasted ore without such addition is known as SAFFLOR. The process of roasting is conducted in such a manner as to leave a sufficient quantity of free arsenic in the product to yield a fusible arsenide or *speiss* of nickel in the subsequent fusion in the smalt furnace. By the addition of carbonate of potash, and fusion, Zaffre is converted into a blue glass, which, when ground and levigated, produces the colour known as *smalt blue*.

Zafran. The Indian name for *Crocus sativus*, whence our name Saffron.

Zagreos (Gr.). In the Orphic *Theogony*, the horned child of ZEUS and PERSEPHONE. He is the favourite of his father, and is represented as seated on the throne beside him, guarded by Apollo and the CURETES. But as in the case of Io, Hera is jealous, and incites the Titans, who kill the child with a sword while he is amusing himself by looking at his own face in a mirror. They then cut up his body and boil it in a cauldron; but Athena bears his heart to Zeus, who punishes the Titans by hurling them into Tartarus. The heart is given to Semele, and Zagreos is born again from her under the form of DIONYSUS. For the probable age of the Orphic *Theogony*, see Grote, *History of Greece*, part i. ch. i.

Zakkoum. An oil obtained in Palestine from *Elæagnus hortensis angustifolia*.

Zaleucus (Gr. Ζάλευκος). The mythical or semi-mythical legislator of the Epizephyrian Locrians. He is described by Diodorus as a disciple of Pythagoras; but nothing can be satisfactorily ascertained from the contradictory legends respecting his life, and in fact his code of laws seems to be the only evidence of his personal existence. How far such evidence can settle the question, can be determined only by a diligent scrutiny of the tales which have gathered round the names of Lycurgus, Numa, ROMULUS and SERVIUS TULLIUS.

Zalmoxis or **Zamolxis** (Gr.). In the Thracian Mythology, a god who dwelt beneath the earth, like Andvari in the Volsung tale. [SIGURDR.] The rationalised Greek version of the myth states that Zalmoxis was a slave of Pythagoras at Samos, and that by abilities and artifice he gained a religious ascendency over the minds of the Thracians. This story Herodotus (iv. 94) refuses to believe. (Grote, *History of Greece*, part i. ch. xvi.)

Zambarone. A Sicilian name for the fibre of the *Agave*, used for making cordage and mats.

Zamia. A genus of *Cycadeaceæ*, consisting of moderate-sized trees, having much of the appearance of palms, and in some particulars of ferns. They have stout generally unbranched stems terminated by tufts of thick pinnated leaves, often spiny at the margins or points. The male and female flowers are borne in cones, composed of woody scales, with a truncated six-sided summit, and each scale of the female flower has two seeds.

The species are natives of Central America, the West Indies, the Cape of Good Hope, and South-eastern Africa, where they frequently constitute a conspicuous feature in the vegetation. The stems of these plants contain an abundance of starchy matter, which is sometimes collected and used as arrowroot. *Z. tenuis* and *Z. furfuracea* are employed for this purpose in the Bahamas. There is abundant evidence to suggest that in former ages some of these cycads grew in this country, as fossilised stems of plants apparently belonging to this or to a closely allied genus are found in abundance in some of the oolitic strata in the Isle of Portland, where they are known to the workmen as fossil birds'-nests, or fossil pineapples.

Zamite. Fossil zamia.

Zasmidium. A genus of Fungi, including that known as the Cellar Fungus. This species, *Z. cellare*, observes Mr. Berkeley, 'is commonly known as hanging down from the roofs of cellars in large masses, or covering corks, bottles, and other matters. It sometimes even penetrates the tissue of the corks, but does not seem to injure the wine like some of the white mycelia. Indeed, the wine merchant en-

courages its growth, as he thinks it an ornament to his vaults, and an indication to customers who visit them that his wine is old.' The cellar fungi are, however, sometimes very injurious.

Zavalite. The name given to a hydro-carbonate of nickel found in Spain; it is probably identical with Emerald-nickel.

Zea (Gr. ζεά, Sansc. and Zend yova, Lith. jawas). A genus of grasses of which *Z. Mays*, or Maize, is the well-known and important cereal so largely grown in the United States of America, where it is generally known under the name of Indian-corn. Though not now found in a wild state, there is little doubt that America is the native region of this plant. Maize is largely cultivated throughout most of the warm-temperate zones of the globe, and probably ranks next to rice as the grain which affords nutriment to the largest number of human beings. It has many qualities to recommend it for culture where the climate is sufficiently warm to ripen the grain properly, growing as it does freely in very different kinds of soil, as well as under dissimilar states of moisture and dryness. The crop is easily saved, and with ordinary care the grain is as easily preserved. Some of the finest samples which have reached Britain in the cob or ear have been grown in Australia, where the climate is very favourable for producing Indian-corn. It is also extensively consumed in many parts of Africa. More than 7,000,000 cwt. of Indian-corn were imported into this country in 1865, the computed value of which was 2,234,396*l.*

Zeagonite. A Vesuvian mineral found in rhombic crystals on Somma. It is identical with GISMONDINE.

Zebra. A name applied, in a general way, to striped species of the section *Asinus*, of the horse kind (*Equidæ*), characterised by a longer tail, tufted at the end, by callosities on the inner side of the fore legs only, and by *braying* instead of *neighing*. Of these striped wild asses, three species are defined: the Zebra proper (*Equus Zebra*, Linn.), the Quagga (*Equus Quaccha*, Gmel.), and Burchell's Zebra (*Equus montanus*, Burch.).

Zebra Wood. A beautiful fancy wood used by cabinet makers, and obtained in Demerara from a tree called *Omphalobium Lamberti*. Another kind is obtained from the wood of the West Indian *Eugenia fragrans*.

Zechstein (Ger.). The upper or calcareous member of the Permian system is thus named in Germany. It consists of: (1) a marly series, *Letten*, often containing rolled fragments of dolomite and crystals of gypsum. It is generally a greyish, bluish, or greenish clay. (2) A fetid limestone, *Stinkstein*, a compact or granulated rock of blackish brown or green colour. (3) A hard cellular magnesian limestone, *Rauwacke*. The whole thickness reaches nearly 100 feet. The zechstein occasionally contains copper ores of galena.

Zedoary. The name by which certain species of *Curcuma* are known. Thus *C. Zerumbet* is the Long Zedoary, and *C. Zedoaria* the Round Zedoary of the shops. They are aromatic plants related to gingers.

Zeilanite or **Zeylanite.** A species of Pleonaste (Spinel) found in black octahedrons, near Candy in Ceylon, from which circumstance it has also been called *Candite*.

Zemindar (from the Persian zemin, *land*). A title introduced into India by its Mohammedan conquerors, conferred in Bengal, and generally throughout the Mogul empire, on the agent employed to collect that share of the produce of the soil which belongs to it. The zemindars were the great landowners of the Mogul empire; but the nature of their tenure has given rise to much dispute. Whether they were hereditary absolute owners of the soil, or only tenants of the sovereign at a fixed rent by way of land-tax for which they were personally responsible, was a question much agitated by writers on Indian subjects at the period of the 'Permanent Settlement' in 1793. By that settlement the rent was to be fixed in the first instance by custom, and the zemindar was then to give the ryot a lease restricted to himself and his assignees on performance of its conditions; his own share being fixed as before at 10 per cent. of the assessment, and his hereditary right secured. A zemindary, i. e. the district of a zemindar, is liable to be sold by government for arrears of revenue, and existing leases with the ryots to be set aside. The zemindary system was a failure. The men who were appointed to this position were frequently persons of low caste, and were despised by the natives. They abused their privileges, to oppress the peasantry, and squandered their resources in extravagance and profligacy. (See Dr. Whewell's edition of the works of Professor Jones; Mill's *History of British India*, vol. v.; M'Culloch's edit. Smith's *Wealth of Nations*, note 19; *Ed. Rev.* vols. xxxi. lxxi.) [RYOT.]

Zenana. This Persian word, more properly written *Zanana*, is used to denote the apartments in Eastern houses set apart for the use of the women in a family.

Zend. The language in which the books of the ZEND AVESTA are composed.

Zend Avesta. The sacred books which embody the religious system of ZOROASTER. The text of these books was brought to Europe by Anquetil du Perron, in the form of a modern Persian translation of the original; but the first European scholar who acquired a knowledge of the Zend language was Eugène Burnouf. This language is closely allied to the Sanscrit of the Veda, and it was chiefly by aid of the latter that the Zend MSS., preserved by the Parsee priests of Bombay [PARSEES], were deciphered. The word Zend is connected by Professor Max Müller with the Sanscrit *chhandas*, a name given to the Vedic hymns [VEDA], Avesta meaning *a settled text*, from the Sanscrit Avasthita, *settled* or *laid down*. The Zend Avesta now consists of four books, the fourth and most celebrated being the Vendidad, which contains an account of the temptation of

Zoroaster, and also furnishes evidence for the existence of *Airya* (Aryans) as a national appellation, the whole space of Asia, vîspem airyô-s'ayanem, being contrasted with the non-Aryan countries, anairyâo dain-hâvô. (Max Müller, *Lect. on Language*, first series, v.—vii.; Gibbon, *Roman Empire*, ch. vii.; Milman, *Hist. of Christianity*, bk. i. ch. ii. and bk. iii. ch. i.)

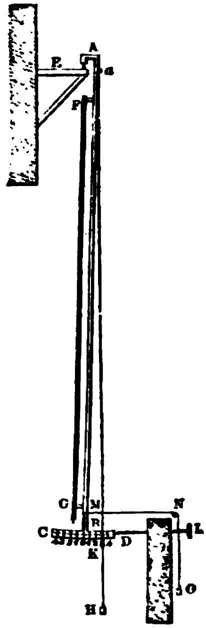
Zendik. In Arabic, a name given to those who are charged with atheism, or, rather, disbelief of any revealed religion, or with magical heresies. The sect of Zendiks opposed the progress of Mohammedanism in Arabia with great obstinacy. It appears to have had many features in common with Sadduceeism among the Jews.

Zenith (from the Arabic). In Astronomy, the top of the heaven, or vertical point; the point directly overhead. The zenith is that point of the celestial sphere which would be intersected by the plumb line, supposed to be indefinitely extended. It may also be defined as the pole of the horizon, from which it is 90° distant. All vertical circles or azimuths necessarily pass through the zenith.

Zenith Distance. The angular distance of any celestial object from the zenith; or the complement of the altitude of the object above the horizon.

Zenith Sector. An astronomical instrument, contrived for the purpose of measuring with great accuracy the zenith distances of stars which pass near the zenith. It was by means of a zenith sector that Bradley discovered the existence and magnitude of two most important astronomical elements—the aberration of light and the nutation of the earth's axis. The instrument has also been generally used (in this country at least) in trigonometrical surveys for determining the difference of latitude of two stations, a purpose for which it is very convenient; for the difference of the zenith distances of the same star, observed at its meridional passages at two places, gives the difference of the astronomical latitudes of the places without any regard to the star's declination. The general description of the zenith sector has been given by the present Astronomer Royal as follows (*Ency. Metr.* art. 'Figure of the Earth'):—

'In the annexed figure AB is a bar of iron with a cross piece CD, the whole in one piece. The top A is formed in such a way that the instrument can be turned half round in azimuth when suspended at the top, and that the bottom can be moved freely in the directions DC or CD. The bracket or other support E, on which it rests, is attached to some firm part of the building. To the bar AB is firmly attached a telescope FG. At a point *a*, near A, is attached a plumb line *a*H; sometimes it is fastened at a point of attachment which is movable, in order that by moving the point of suspension the plumb line may be made to pass over a fine dot at *a*. The limb CD is graduated, sometimes on a circular arc of which *a* is the centre, and sometimes on a straight line. LD is a screw passing through a block strongly connected with the floor, and acting with its point against the end D of the piece CD; and MNO are a string and weight pressing the sector against the point of the screw.'



The method of observing with the zenith sector is this: A clock being regulated by transits of stars, the direction of the meridian is found, and guides fixed to compel the sector to move in the meridian. When a star is to be observed, the screw LD is turned till the plumb line falls exactly on some point K of the graduated arc, such that the telescope is very nearly directed to the point through which the star will pass when it comes to the meridian. When the star enters the field of view, the screw is again turned till it appears to glide exactly along the horizontal wire fixed in the focus of the eye-glass; and the motion of the screw being ascertained, and the value of the divisions known, the apparent zenith distance of the star is found. But it is evident that this is not the true zenith distance, unless the zero point of the divisions on the scale be quite accurate, i. e. so placed that when the plumb line falls on it the optical axis of the telescope shall be exactly vertical. It is impossible to insure this accuracy; but it is easy to see that if the instrument be turned half round in azimuth, and the same observation made, the apparent zenith distance will be just as much greater than the true as in the former determination it was less. The mean of the two will therefore be the true zenith distance of the star.

The advantages of the zenith sector are these: The stars observed being very near the zenith, the tremor and dancing which generally affect stars in other positions are seldom seen; there is no uncertainty about the effects of refraction; the telescope and the whole instrument are not subject to flexure; and the variation of temperature produces no sensible effect.

For a detailed account of Ramsden's zenith sector used in the measurement of the English arcs of the meridian, see the second volume of the *Trigonometrical Survey of England and Wales*, or *Phil. Trans.* for 1803. This superb instrument was unfortunately burnt in the great fire which took place in the tower of London

in October 1841. Another sector, on a different plan from that above described (the zenith point being determined by levels), has been constructed for the use of the survey by Troughton and Simms, under the direction of the Astronomer Royal. A description and drawing of the new instrument is given in the *Monthly Notices of the Royal Astronomical Society* for May 1842.

Zeolite (Gr. ζέω, *to boil*). A name formerly given to Mesotype and Stilbite. It is now, however, used in a more extended sense to denote a family of silicates, the chief distinguishing feature of which is that they always contain a large proportion of water, varying from 4 to 20 per cent. They also possess in common the property of melting with considerable ebullition before the blowpipe, and of forming a precipitate of gelatinous silica in hydrochloric acid, and of yielding a colourless streak.

The Zeolites usually occur in volcanic rocks in the form of crystals, or of foliated and radiated masses, filling cavities, veins, and fissures—sometimes, as in basalt, they constitute an essential ingredient of the rock itself. The principal species composing the group of Zeolitic minerals are: ANALCIME, APOPHYLLITE, CHABAZITE, GMELINITE: HARMOTOME, HEULANDITE, LAUMONTITE, MESOLITE, NATROLITE, PHILLIPSITE, PREHNITE, SCOLEZITE, STILBITE, THOMSONITE.

Zephyrus (Gr. ζέφυρος, akin to ζόφος, *darkness*, a word which has many forms, as δνόφος, γνόφος, κνέφας, νεφός, νεφέλη, Lat. nubes). In Greek Mythology, the west wind blowing from the dark land, in which dwell NEPHELÊ and the children of the mist. In the Hesiodic *Theogony*, Zephyrus is described as a son of Astræus (*the starry*) and Eos (*the morning*). By the Harpy Podargê (of the glistering feet) he became the father of Xanthos and Balios, the undying horses of Achilleus. [CHARITES.]

Zero (Ital.?). A term generally used in reference to the thermometer, implying the point at which the graduation commences. The zero of Réaumur's and of the centigrade thermometer is the freezing point of water. The zero of Fahrenheit's scale is 32° below the point at which water congeals, being about the temperature of a mixture of salt and snow. [THERMOMETER.]

Zetes (Gr. ζήτης). In Greek Mythology, a son of Boreas and Oreithyia. Like his brother Calais, he was born with wings, and took part in the Argonautic expedition. [MYSTERIES.] They were engaged also in pursuit of the HARPIES, and were slain by HERACLES in Tenos.

Zeugite (Gr. ζευγίτης, *yoked* or *joined together*). A native phosphate of lime which is met with in white or slightly yellowish and brownish amorphous masses, in guano at the Key of Sombrero.

Zeuglodon (Gr. ζεύγλη, *a yoke*, and ὀδούς, *a tooth*). A genus of gigantic cetacean animals, the remains of which have been found in the miocene strata of Europe and North America. The teeth of this carnivorous whale were first described and figured by the mediæval palæontologist Scilla. The American remains have been erroneously referred to a genus of reptiles, and termed Squalodon, Basilosaurus, and Dorudon by various American authors. The entire skeleton of the largest species (*Zeuglodon Harlani*) indicates an animal about seventy feet in length. The skull is very long and narrow; the nostril single, with an upward aspect, above and near the orbits. The jaws are armed with teeth of two kinds, set wide apart; the crown of the tooth being contracted from side to side in the middle of its base, so as to give its transverse section an hour-glass form (whence the name). The Zeuglodonts form a distinct family of Cetacea, intermediate between that order and the Sirenia.

Zeugma (Gr. *a yoke*). A figure in Grammar, by which an adjective or verb which agrees with a nearer word is referred also, by way of supplement, to one more remote.

Zeus (Gr.). This name for the supreme god of the Greeks is etymologically identical with the Sanscrit *Dyaus*, the Latin *Jovis* (Jupiter), the Anglo-Saxon *Tiw* [TUESDAY], the Eddic god TYR, the Old High German Zio. The analysis of language and mythology shows that this god was originally the supreme deity of the whole Aryan family of nations. Among the Hindus this deity was at a comparatively early period eclipsed by Indra, the god who by smiting VRITRA brings rain upon the earth; but Indra is himself the son of Dyaus-pitâr, the Ζεὺς πατὴρ of the Greeks, the Diespiter and Jupiter of the Latins. This name Dyaus is derived from the same root which yields the verb *dyut*, to beam; and in the modern Hindustani dyu remains the name for *sky* and *day*, with which latter word it is identical. In this fact we have the reason for the slender hold which the name retained in the formation of their mythology. Among the Homeric Greeks, with whom words like ἀήρ, αἰθήρ, and οὐρανός, were the common names for air, æther, and heaven, Zeus became more and more a person, being either exalted as the Supreme Impassible Creator, just and holy, or debased by the anthropomorphising process inseparable from the growth of mythology. But although the name ceased to be to the Greek a mere appellative for the heavens, still, in harmony with the original idea, Zeus in the partition of all things remains the lord of the æther or highest heaven, while he bestows the nether regions on HADES, and the sea on POSEIDON. The same idea is manifest in the prayer, ὗσον, ὦ φίλε Ζεῦ, κατὰ τῆς ἀρούρας τῶν Ἀθηναίων (*rain, O dear Zeus, on the land of the Athenians*), as well as in the expression of Ennius, Aspice hoc sublime candens quem invocant omnes Jovem (*see this glistening heaven which by all is named Jove*). With these may be compared the phrases, *sub dio vivere*, to be in the open air; *sub Jove frigido*, under a cold sky; *malus Jupiter*, stormy weather. Of the original epithets of Dyaus, some were transferred to Indra, who thus becomes, for

example, Indra-sthâtas, the Jupiter Stator of the Latins.

Thus, then, among the Greeks, the conceptions of Zeus parted off into two streams almost at the fountain head. On the one hand we have the anthropomorphised god, with his relations to other gods and beings duly defined according to the laws which determine the growth of myths; on the other, we find the idea (which, as time goes on, becomes clearer and stronger) of an Infinite and Eternal God, holy, just, and true, who desires righteousness in men and watches over them for their good. Although the mythical notions come uppermost in the language of ordinary life, yet, whenever the man is thrown back upon his own thoughts in times of need, distress, or excitement of any kind, he reverts instantly to a Zeus, who has nothing in common with the Zeus of the Homeric Olympus. For this Zeus is capricious, tyrannical, and lustful, as every being must be for whom language, both harmless and beautiful when applied to the phenomena of the heavens, has been translated into the conditions of human society; and such a Zeus could be no fit object of reverence, for, in the words of Euripides,

εἰ θεοί τι δρῶσιν αἰσχρὸν, οὐκ εἰσὶν θεοί.

'If the gods do aught unseemly, then they are not gods at all.'

Zeus then, as the sky or air, might be regarded as producing time or as produced by time. In the former case he would be Zeus Kronion, or the ancient of days: in the latter, he would be the son of Kronos, who is probably nothing more than a mythical being evoked from that which had been a mere epithet. But the air or heaven covers everything as with a garment, and so Zeus would be Ouranion; from which name sprang the concrete Ouranos [Uranus], who in the Hesiodic *Theogony* is assigned as a father to Kronos, and who reappears in the Vedic Varuna. Having advanced thus far, the growth of the myth next assigned to him a wife in Hera, a name connected by some with the Sanscrit svar, *the bright sky*, and sûrya, *the sun*. (Cox, *Manual of Mythology*, p. 24.) But the bright heaven through which the sun journeys may be regarded as the cause of all fertility, and the fruits of all lands may be looked upon as his children; and thus Zeus, like Heracles, became a being who had his earthly loves wherever he went, and took pride in recounting their numbers. It is obvious that the extension of this process must render the character of the being portrayed continually more gross and repulsive; and thus we have in Pindar and in Plato strong expressions of disgust for the coarseness and immorality of tales which were not only harmless but exquisitely graceful in their original form. [Theology.]

But while the mythical descriptions were becoming more and more sensual, the conception of the spiritual Zeus was becoming more pure and refined. The former process is seen in the Hesiodic *Theogony* as compared with the Homeric poems, the latter in the Hesiodic *Works and Days*. This poem, which in the view taken of human life exhibits a temper not unlike that of the book Ecclesiastes, manifests a religious spirit which cannot be too carefully taken into account. Zeus here is the avenger of injustice (237); he looks down from heaven upon the children of men to see if they will do righteousness (247); the eye of Zeus is everywhere, and he knows all things (265); and for the good of men he has ordained labour to be the lot of their life (287). But even in the Homeric poems, the Zeus to whom real prayer is offered is not the Zeus who indulges himself in sensuality and cruelty; the prayer of Achilleus is not offered to a lying god who owns no law for himself and cannot be a law for man. The later poets rise to the knowledge that the word Zeus is a mere name, utterly inadequate to express the conception of the Infinite and All-righteous Maker and Preserver of all things.

The etymological changes of the name are almost numberless. To those which have been already mentioned may be added the forms connected with it by the transition of *dy* (Dyaus) into *j* (Jupiter) or *dj*, as in the old form Diovis, met with in Oscan inscriptions, in the old Italian divinity Vejovis, in Jan, the older form of Janus (January), which again is the same as Juno, and is resolved also into Dianus and Diana. This last name with the so-called Digamma becomes Divâna, the heavenly, dív-inus, the divine. Akin to the root of Dyaus, is the Sanscrit deva, *a god*, a word denoting originally *brightness*; and thus Vritra is called adêva, the *atheist* or enemy of the gods. Deva then is the Latin Deus, the Greek θεός, the Lithuanian Diewas.

The common Homeric epithet of Zeus, εὐρύοπα, or *broad-faced*, explains itself, and is referred to the class which includes Europa, Euryanassa, &c. [Telephassa.]

The cave of Dictê, in which, according to the Cretan legend, Zeus was born, is the cave or abyss from which springs the light of day. The name Dictê belongs, as some have thought, to the same root with δείκνυμι, *to show*; Sanscrit, dic; Latin, indicare; German, licht, zeichen; English, *light*, *token*. To this root also belongs, probably, the epithet Dictynna, applied to Artemis as employing δίκτυα, or nets, in hunting, and the name of Dictys, who rescues Danaê from the sea at Seriphos.

For a more full examination of the subject, the reader is referred to Max Müller, *Comparative Mythology*, and *Lectures on Language*, second series, x.; Bréal, *Hercule et Cacus*; Cox, *Gods and Heroes*, and *Thebes and Argos*, Introductions. The mythical relations of Zeus to gods and men are minutely traced by Mr. Grote (*History of Greece*, part i. ch. i.); and the most important of these are noticed in the following articles: Aphroditê; Arês; Charites; Hephæstus; Hera; Heracles; Hermes; Io; Lycaon; Memnon; Minerva;

PANDORA; PARIS; PERSEPHONE; PERSEUS; POSEIDON; PROMETHEUS; RHEA; SARPEDON; SEMELÊ; TANTALUS; THESEUS; TITANS; URANUS; VESTA; ZAGREOS.

Zeuxite (Gr. ζεῦξις, *a yoking*, from its occurrence in the *United Mines*). A variety of Iron-Tourmaline formerly met with at Huel Unity in Cornwall, in small translucent and acicular blackish-green crystals much interlaced, and having the appearance of asbestiform Actinolite. It is a ferro-silicate of alumina.

Zeysoum. An Egyptian name for the flower-heads of *Santolina fragrantissima*, a substitute for chamomiles.

Ziega or **Serai.** After rennet has ceased to produce the coagulation of milk, the addition of acetic acid occasions a further separation of curd, to which the above names are applied.

Zieria (after M. Zier). A genus of *Rutaceæ* confined to the continent of Australia, and chiefly to the eastern coast, extending as far as the tropics. They are small trees or shrubs, with opposite simple or trifoliate leaves, full of pellucid dots; and they usually bear axillary, few or many flowered panicles of white flowers.

The *Z. lanceolata* of Tasmania is a shrub, and is called Stinkwood by the colonists, on account of its fetid smell. One common at Illawarra, and there called Turmeric-tree, has a very yellow inner bark, suitable for dyeing, and also a yellow close-grained hard wood, which is valuable for ornamental purposes, and probably might be used for engraving.

Zigzags. In the attack of a fortress, approaches connecting the parallels. They are directed so that their prolongations fall alternately to the right and left of the fortress, and clear of the most prominent salients of the covered way. [FORTIFICATION.]

Zillah (Hind. Zilâ). In British India, the designation of a province or tract of country constituting the district of a commissioner or circuit judge, and the extent of a chief collectorate.

Zinc (Ger. zink, perhaps akin to zinn, *tin*). (Zn.) This metal was first mentioned by Paracelsus, but its ores were resorted to at a much earlier period for the manufacture of brass. The zinc of commerce is procured from the native sulphide (*blende*) or from the carbonate (*calamine*). The ore is wasted in a reverberatory furnace (by which carbonic acid is driven off from the calamine, and sulphur from the sulphide), and is then mixed with charcoal, and put into earthen pots, not unlike oil-jars, six of which are usually placed in a circular furnace. Each pot has an iron tube passing from its lower part, through the floor of the furnace, and dipping into water; they are everywhere else firmly luted. Upon the application of a full red heat, the metal distils through the tube into the water beneath, whence it is collected, melted, and cast into cakes. This process is called *distillatio per descensum*. Commercial zinc generally contains traces of sulphur, iron, and arsenic.

Zinc is a bluish-white metal, rather hard, of a specific gravity of 6·8 to 7. It has a peculiar odour when breathed upon, or handled with moist fingers. In its ordinary state and at common temperatures it is tough, but becomes brittle when its temperature approaches that of fusion, which is about 770°. At a temperature between 220° and 300°, it is ductile and malleable. If slowly cooled after fusion, its fracture is very crystalline.

A surface of clean zinc exposed to dry air remains bright; in damp air it tarnishes. Under water it becomes enfilmed with hydrated oxide, or carbonate. At common temperatures it does not decompose water, but it does so at a red heat, or in the presence of acids. The energy with which zinc is acted on by dilute sulphuric acid is greatly dependent upon the purity of the metal: when perfectly pure, the action is feeble; but when it contains other metals, it becomes rapid, owing to a galvanic action. Zinc, in consequence of its lightness and cheapness, is much used for roofing, gutters, and chimney-tops; but it should not be riveted with copper or iron, the contact of which accelerates its destruction by electric action.

The great attraction between zinc and oxygen is shown by the facility with which many of the other metallic oxides, in solution, are reduced to the metallic state by its means. Its important electro-generative power in voltaic arrangements, must also be referred to this cause.

The only salifiable oxide is obtained by intensely heating the metal exposed to air, when its vapour takes fire, burns with a very bright flame, and forms a white flocculent tasteless substance, formerly called *nihil album*, *philosopher's wool*, and *flowers of zinc*. Zinc-leaf may also be inflamed by a spirit-lamp, and will continue to burn brilliantly even when removed from the flame. For pharmaceutical use, oxide of zinc combined with the carbonate is procured by decomposing a hot solution of sulphate of zinc by carbonate of soda. It is commonly met with in the form of a white powder, and is much used as a pigment, and in medicine as a tonic, and external application. Sir William Burnett's *disinfectant liquid* and preservative against dry rot is a strong solution of *chloride of zinc*: it is an acrid poison.

Sulphate of zinc, or white vitriol, is used in astringent lotions, and also as an emetic. Two important native compounds of zinc, BLENDE and CALAMINE, are described under those heads.

Zinked Iron; *Galvanised Iron*.—Plates of hot iron dipped into melted zinc acquire an appearance in some measure like that of tin-plate, for which they are a valuable substitute, inasmuch as the iron is prevented from oxidation by the electrical relations of the metals. Hurdles, fences, and all out-of-door iron-work, as well as implements used in damp situations, and employed in contact with water, may be thus defended. The wires of electric telegraphs are also usually of zinked iron. The zinking of iron is generally per-

formed by dipping the iron, previously well cleaned, into melted zinc, the surface of which is covered with sal-ammoniac to prevent oxidation, and so to enable the iron to become thoroughly wetted, as it were, with the zinc. The zinc is fused in large wrought-iron vessels, placed over proper furnaces; and after the frequent dippings of the iron articles, there is ultimately found at the bottom of the melted metal a quantity of a granular alloy of zinc and iron. The process is not applicable to the generality of vessels used for culinary purposes, in consequence of the contaminations by oxide of zinc which would often ensue, especially with acidulous liquors. In using zinked iron, care should be taken that where nails or rivets are required, they should also be coated with zinc. [Bell Metal; Brass; Bronze.]

Zinc Bloom. A hydrated carbonate of zinc or a mixture of carbonate of zinc with the hydrous oxide, resulting from the decomposition of Calamine. It occurs in white, yellowish or greyish incrustations, or reniform earthy masses, at Bleiburg and Raibel in Carinthia, also at Santander in Spain.

Zinc Spar. [Smithsonite.]

Zinc White. The product of the combustion of zinc in air. It is a white powder forming an excellent paint where mixed with the requisite proportions of oil and turpentine. The paint must not be too thin, or it will not cover; nor must the oil be in excess, or it will dry of a brownish tint.

Zincamide. A white solid obtained by the substitution of zinc for one-third of the hydrogen in ammonia.

Zincethyl. A colourless volatile liquid, composed of zinc and ethyl. It has powerful affinities for oxygen, igniting spontaneously on exposure to air. It is formed by heating zinc with iodide of ethyl under pressure.

Zincite. Native oxide of zinc found with Franklinite and Calc Spar at Franklin and Stirling Hill in New Jersey. Its colour is owing to the accidental presence of a small quantity of oxide of manganese.

Zinckenite. [Zinkenite.]

Zingiber (Gr. ζιγγίβερις). This name is now adopted by botanists to designate the typical genus of *Zingiberaceæ*, which consists of herbaceous Indian plants, with creeping jointed woody rootstocks, from which are sent up, every year, stems surrounded by sheathing leaves arranged in two ranks, cone-shaped spikes and flowers protected by bracts. The distinguishing features of the flowers are that the lateral inner lobes of the corolla are absent, and that the filament is prolonged beyond the anther in the form of a long beak.

The most important species is called *Z. officinale*, the rhizomes of which furnish the well-known spice called Ginger. The plant is largely cultivated in the East and West Indies, as well as in Africa and China. It is supposed that there are two varieties, one producing darker-coloured rhizomes than the other, this difference in colour being independent of the mode of preparation. The young rhizomes preserved in syrup are imported from the West Indies and China, and form the conserve known as preserved ginger, that imported from the West Indies being preferred to the Chinese kind.

The dried rhizomes or (as they are called in commerce) *races* are in the West Indies prepared for use when they are about a year old. They are then dug up, cleansed, scraped, and dried in the sun, and in this state form the uncoated ginger of the shops; but when the outer skin is not thus removed, the ginger is called *coated*, and has a dirty appearance. The softer kinds of ginger are preferred by the merchants, the hard shrivelled inferior kinds being used for grinding. The darker kinds of ginger are sometimes bleached by exposure to the fumes of chloride of lime or burning sulphur. East Indian gingers are not so largely imported or so highly esteemed as the West Indian kinds, the latter being less liable than the former to the attacks of worms. African ginger is imported in small quantities from Sierra Leone, while China exports only the preserved ginger already mentioned.

Zingiberaceæ (Zingiber, one of the genera) or **Scitamineæ.** A natural order of herbaceous monandrous Endogens, inhabiting the tropics, and characterised by its solitary stamen with a two-celled anther, and the presence of the vitellus around the embryo. The group is distinguished from *Musaceæ*, by the latter having five or six stamens, with a calyx and corolla of the same texture; from *Iridaceæ*, by two of the stamens being either deformed or abortive; and from *Marantaceæ*, by the single stamen being placed opposite to the labellum or anterior division of the inner series of the corolla, and proceeding from the base of the posterior outer division, and having only one cell. Cardamoms are the seeds of several plants of this order, which are, however, principally valued for the aromatic stimulating properties of the root or rhizome; such are found in Ginger (*Zingiber officinale*), Galangale (*Alpinia racemosa* and *Galanga*), and Zedoary (*Curcuma Zedoaria* and *Zerumbet*). Turmeric, a substance half dye and half condiment, is the powder of the rhizoma of *Curcuma longa*.

Zinkenite. A native sulphantimonite of lead, composed of 40 per cent. of sulphide of lead and 60 sulphide of antimony. It occurs in bright steel-grey six-sided prisms terminated by low six-sided pyramids at the antimony mine of Wolfsberg, near Holberg in the Harz. Named after its discoverer, Zinken.

Zinnwaldite. A variety of Lithia-Mica (*Lepidolite*) from Zinnwald.

Zinzeyd. A Persian name for the fruit of *Elæagnus orientalis* as an article of dessert.

Zippeite. A native sulphate of Uranium (named after Professor Zippe), of which there are two varieties, one containing copper, of which the other exhibits no trace. It has been found in Cornwall at the Callington tin-mine, at

Carharrack near St. Day, at the Withiel iron-mine, at Restormel, Huel Edward near St. Just, and at St. Michael's Mount, coating Mica.

Zircon. A silicate of zirconia found in the sand of the rivers of Ceylon [HYACINTH; JARGOON], in the syenite of Norway, &c., also at Strontian in Argyleshire, the isle of Harris in Sutherlandshire, and in the auriferous streams of the Croghan Kinshela mountain in Ireland.

Zircon occurs in crystals, generally square four-sided prisms terminated by four-sided pyramids, and also in grains, sometimes white, but more frequently red, brown, yellow, green, or grey. The colourless or slightly smoky kinds are called *Jargoon*; the bright red, *Hyacinth*, and the greyish or brownish, *Zirconite*.

When of a fine colour and transparent, these are sometimes used in jewellery.

Zirconite. A greyish or reddish-brown variety of *Zircon* found at Minsk in the Ural, and also at Scalpay in the island of Harris, one of the Hebrides.

Zirconium. The metallic base of *zirconia*, an earth discovered in 1789 by Klaproth in the jargon or zircon of Ceylon. Zirconium has only been obtained in the form of a black powder, which when heated in the air burns into the oxide. The salts of zirconia are distinguished from those of alumina and glucina by being precipitated by all the pure alkalies, and by being insoluble when they are added in excess. Its equivalent is 34, and the formula of its oxide Zr_2O_3.

Zizania (Gr.). A genus of grasses, the most interesting species of which is the *Z. aquatica* or Canadian rice, a well-known plant of North America, where the large seeds yield a considerable amount of food to the wandering tribes of Indians, and also feed immense flocks of wild fowl. It is sometimes called *Hydropyrum esculentum*.

Zizyphus (Gr. *ζίζυφον, the jujube-tree*). The Jujube or Lotus genus, a rather extensive group of *Rhamnaceæ*, having a wide geographical range, abounding, however, principally on the borders of the tropics in the Old World. The fruits of several species have an agreeable flavour. Those of *Z. vulgaris* are commonly eaten, both in a fresh and dried state, in the countries bordering on the Mediterranean, and afford the Jujube fruits of the shops; they are rather acid when fresh, but the dried fruits are more agreeable, and are given to allay cough. The lozenges sold as Jujubes are commonly but erroneously said to be flavoured with them. *Z. Jujuba*, an Indian species, yields an excellent dessert-fruit, and is largely cultivated by the Chinese, who recognise a great number of varieties, differing in the shape, colour, and size of the fruits. Those of one variety are called Chinese Dates, from their resemblance to dates. Some of them are sold in the market under the name of Japonicas. *Z. Lotus* is one of the many plants supposed to have yielded the seductive sweet fruits from which the ancient LOTOPHAGI took their name. Another African species, *Z. Baclei*, is the Lotus mentioned by Mungo Park as being used for making into bread, which has the taste of gingerbread, and also for the preparation of a pleasant beverage.

Zoanthus (Gr. *ζωός, living*, and *ἄνθος, a flower*). The name of a genus of Polypes, comprehending those which possess the complex structure of the *Actiniæ*, but consist of different individuals adhering to a common fleshy basis, in which calcareous spicules are sparingly scattered.

Zocle. [SOCLE.]

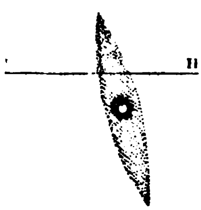
Zodiac (Gr. *ζωδιακός*, from *ζώδιον*, dim. of *ζῷον, an animal*; because the constellations of the ecliptic are for the most part represented in celestial charts by the figures of animals). An imaginary zone or belt in the heavens, extending to about 8° or 9° on each side of the ecliptic, which divides it in the middle. No use is made of the zodiac in astronomy; the name only indicates that region of the heavens within which the apparent motions of the sun, moon, and all the greater planets are confined. Three of the new planets, Juno, Ceres, and Pallas, have inclinations which exceed the limits of the ancient zodiac, and are therefore sometimes called *extra-zodiacal* planets; but Vesta is also sometimes included in the same description. [PLANET.]

The zodiac is divided into twelve equal parts, called *signs*; which are designated by the names of the constellations with the places of which the signs anciently corresponded. They are, Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricornus, Aquarius, and Pisces. The signs are counted from the vernal equinox, one of the points in which the equator intersects the ecliptic; whence, in consequence of the regression of the equinoctial points, their position with respect to the constellations or fixed stars is greatly different from what it was in remote ages. Some time prior to Hipparchus, the first points of the constellations Aries and Libra corresponded to the vernal and autumnal equinoxes; those of Cancer and Capricorn to the summer and winter solstices: at present, the difference is about 30°. The vernal equinox now happens in the constellation Pisces, the summer solstice in Gemini, the autumnal equinox in Virgo, and the winter solstice in Sagittarius; but the vernal equinox always corresponds to the first point of the sign Aries, the summer solstice to the first of Cancer, and so on. On this account it is necessary to distinguish between the *signs* of the zodiac, which follow the motions of the equinoctial points, and the *constellations* of the zodiac, which are immovable in the celestial sphere.

It has been supposed that the constellations of the zodiac were invented in Egypt in a very remote age, and that they had reference to the divisions of the seasons and the agriculture of that country at the time of their invention. If we go back to a period of about 4,500 years, the constellations Aquarius and Pisces, at the season of the overflow of the Nile, would be diametrically opposite to the sun, and would

consequently rise at sunset. Virgo, usually represented as a woman with an ear of corn in her hand, would be the constellation rising at sunset in the time of the harvest in Egypt. Such conjectures, however, it is easy to conceive, are at best extremely uncertain. (Dupuis, *Mémoire sur l'Origine du Zodiaque*; Biot, *Recherches sur l'Astronomie Egyptienne*; Montucla, *Histoire des Math.* tom. i.; Bailly, *Hist. de l'Astr. Ancienne.*)

Zodiacal Light. In Astronomy, a faint nebulous aurora which surrounds the sun in the plane of its equator. This curious phenomenon was observed by Kepler, who supposed it to be the solar atmosphere; but it was first accurately described by Dominic Cassini, who gave it the name by which it is now known. It is visible immediately before sunrise or after sunset, in the place where the sun is about to appear or has just quitted in the horizon. It has a flat lenticular form, as represented in the annexed figure, extending from the horizon HH obliquely upwards, and following the course of the ecliptic, or rather of the sun's equator. For this reason it is scarcely visible in our latitudes, excepting in those seasons when the plane of the sun's equator is most nearly perpendicular to the horizon. The most favourable times for observing it are in the months of April or May, in the evening, or at the opposite season of the year before sunrise. At other times, the plane of the solar equator being more oblique, and the luminous pyramid inclined in the same degree, it rises so little above the horizon that its light is effaced by the atmosphere of the earth. The apparent angular distance of its vertex from the sun varies, according to circumstances, from 40° to 90° or 100°, and the breadth of its base perpendicular to its axis from 8° to 30°. It is extremely faint and ill-defined, at least in this climate; though it is better seen in tropical countries.



Many opinions have been entertained respecting the nature and cause of this singular phenomenon. Cassini thought it might proceed from the blended light of an innumerable multitude of little planets circulating about the sun, as the Milky Way owes its appearance to the light of agglomerated myriads of stars. Euler endeavoured to prove that it proceeds from the same causes which produce the tails of comets. Kepler had ascribed its appearance to the solar atmosphere; and the same hypothesis was adopted by Mairan and others, till it was shown by Laplace to be untenable for the following reasons: In the first place, the solar atmosphere cannot extend beyond the distance at which the centrifugal force would be balanced by the attraction; but this point lies far within the orbit of Mercury, the greatest elongation of which is 28°, whereas the zodiacal light has been observed to extend to 100° from the sun. In the second place, in order that the spheroid of the solar atmosphere may be in equilibrium, the ratio of the equatorial to the polar axis cannot exceed that of 3 to 2; whence its form would not correspond with the lenticular appearance of the zodiacal light. Sir John Herschel remarks, that 'it may be conjectured to be no other than the denser part of that medium, which, as we have reason to believe, resists the motion of comets; loaded, perhaps, with the actual materials of the tails of millions of those bodies, of which they have been stripped in their successive perihelion passages. An *atmosphere* of the sun it cannot be.'

According to the most recent hypothesis of Mayer and William Thomson, the zodiacal light has been held to consist of a vast number of meteorites which circulate around the sun, and are gradually falling into that luminary, their impact contributing to restore the solar heat and light lost by radiation. But considerable doubts have been thrown on this theory, and moreover some observers who have had ample opportunities of observing the phenomenon in the tropics, where it is generally to be seen in all its splendour, affirm that the ring instead of being within the earth's orbit is actually outside it. In fact, M. Liais, who has observed it with the greatest attention in Brazil, asserts that he has often seen it spanning the sky from west to east. If this be confirmed by subsequent observers, the fact either that it really lies outside the earth's orbit, or that it is of considerable eccentricity, will be established.

Zohac. In Mythology. [Thraetana; Vritra.]

Zohar (Heb. *splendour*). A Jewish book, highly esteemed by the rabbis, and supposed to be of great, though altogether unascertained, antiquity. It consists of cabalistical commentaries on Scripture, especially on the Pentateuch. It has been translated into Latin (ed. 1680).

Zoisite. A silicate of alumina and lime, formerly considered a variety of Epidote, and named after its discoverer, the baron von Zois. It is said to occur in fine crystals of a greyish-brown or olive colour at Hollyhill near Strabane, Tyrone.

Zollverein (Ger. *toll-union*). Up to the year 1837, the inconveniences which affected trade in consequence of the various customs duties levied at the frontier of the numerous German states, were exceedingly vexatious and mischievous, besides which the costs and charges of collecting the revenue were exceedingly large. At the instance, therefore, of Prussia, on August 23, 1837, at a convention held at Munich, a number of states entered into a union for fiscal purposes. It was agreed that fixed taxes should be levied on commodities at their entrance into any parts of the German frontier which should be occupied by any of the states taking part in the convention, that the pro-

ceeds should be paid into a common fund, should be distributed among the several states forming the convention, on the basis of population, and that the arrangements should be subject to subsequent and periodical revision.

The establishment of the Zollverein was an act of great financial wisdom, and reflects great credit on the intelligence and sagacity of Prussia. But no states in Northern Germany at first entered into the arrangement, and for a considerable time the effectual working of the plan was much impeded. In time, the great inconveniences which ensued to states which excluded themselves from the Zollverein, amounting in effect to considerable penalties, brought the malcontents gradually round, and at the beginning of the year 1866 all the North German communities and most of the Southern were enrolled. It is not likely, since the face of Germany must needs be changed by the events of the late war, that the extent of the Zollverein is likely to be narrowed, or its efficiency impaired in future.

In order to facilitate the estimate of taxes, an arrangement was entered into by which the North and South German currencies, the chief elements in which are the thaler and florin respectively, were mutually valued. According to the reckoning of the former, the *Nord Deutsche Währung*, the pound of fine silver is equal to 30 thalers; according to the latter, the *Süd Deutsche Währung*, it is equal to 45 Austrian and 52½ Rhenish florins; so that two North German dollars are equivalent to three Austrian and 3½ South German or Rhenish florins; or, to interpret these values in English money, the thaler, or North German dollar, is worth 2*s.* 10¾*d.*, the Austrian florin 1*s.* 11¼*d.*, the South German or Rhenish 1*s.* 7¾*d.*

The original members of the league were Prussia—North; Bavaria, Würtemburg, Baden, Hesse, Nassau, and Frankfort—South.

At the beginning of the year 1866, the Northern states were Prussia, Saxony, Hanover, Electoral Hesse, the grand duchy of Saxony, Saxe Altenburg, Saxe Gotha, Brunswick, Oldenburg, and Birkenfeld, the two Anhalts, the two Schwarzburgs, Waldeck, Pyrmont, the two principalities of Reuss, Schaunberg Lippe, and Lippe. The Southern were Bavaria, Würtemburg, grand duchies of Baden and Hesse, Saxe Coburg, Nassau, Schwarzburg Rudolstadt, Hesse Homburg and Frankfort.

Zomidine (Gr. ζωμός, *broth*). The aqueous extract of flesh: one of the substances giving the odour to meat-broth, and probably the same as OSMAZOME.

Zona Pellucida (Lat.). In Embryology, the external investment of the ovarian ovum in mammalia, which consists of a thick transparent membrane, and appears, under the microscope, as a bright zone or ring.

Zone (Gr. ζώνη, *a girdle or belt*). In Astronomy, a portion of the celestial sphere included between two parallel circles. In Geography, the terrestrial zones are the five broad spaces or belts into which the surface of the earth is divided by the two tropics and the two polar circles. The space included between the tropics is called the *torrid zone*; its breadth is equal to 47°, or twice the sun's greatest declination, and it is divided into two equal parts by the equator. That included between the tropic of Cancer and the arctic circle is called the *north temperate zone*; and that between the tropic of Capricorn and the antarctic circle, the *south temperate zone*. The breadth of each of these is 43°. The space between the arctic circle and the north pole is the *north frigid zone*; and that between the antarctic circle and the south pole is the *south frigid zone*. [EARTH; GEOGRAPHY.]

Zoography (Gr. ζῶον, and γράφω, *I write*). The description of animals.

Zooid (Gr. ζωοειδής, *like an animal*). A term used to denote organic bodies, sometimes free and locomotive, e. g. spermatozoa, which resemble but are not animals. It has been misapplied to parthenogenetic progeny, which, in whatever degree they may be like their parents or unlike them, are equally either animals or plants. Thus the *bud* of the oak-tree, as that of the Hydra-polype, is the *zooid* of each respectively.

Zoolatry (Gr. ζῶον, *an animal*, and λατρεία, *worship*). A term employed to denote that worship of animals which was the characteristic of the ancient Egyptian religion most remarked upon by foreigners.

Zoology (Gr. ζῶον, and λόγος). The science of animals. It teaches their nature and properties, their classification, and their order of succession upon and their distribution over the earth.

A knowledge of the nature of animals, as it implies that of their organisation, and of the functions and interdependencies of their component parts, constitutes the two great branches of zoology, called *Zootomy*, or comparative anatomy, and *Physiology*. The doctrine of the succession of species of animals upon the earth, as it relates principally to such as no longer exist, is included in a third branch of the science of animals, called *Palæontology*, with which is closely connected that which treats of the geographical distribution of existing species. The term *Zoology* is practically restricted to the science of the outward characters, habits, properties, and classification of animals.

A classification is essentially based on the ideas of likeness, unlikeness, and proportion in its subjects. When it is purposed to define, in a classification of animals, their different degrees of resemblance, a natural system is aimed at. When a classification is restricted to the enunciation of a few likenesses which may be most readily detected and most easily retained in the memory, it becomes an artificial system. A likeness extends as far as a character is common; and the more extended or common the property or structure on which such character is founded, the more important and essential it becomes as an element of the classification.

Zoologists having ascertained as many of the characters common to all animals as served to form their complex idea of an animal, have, in the next place, sought to discover the difference which, added to the idea or definition of the animal, would form logically the most extended species of that genus.

Such a difference or character is not to be detected by a superficial examination. Aristotle thought that he had found it in the blood, recognising as blood only the red-coloured nutrient fluid, like that which flows in the arteries and veins of man. His primary division of animals was therefore into Sanguineous and Exsanguineous animals; the *Enaima* and the *Anaima*. The Enaima were the beasts, birds, reptiles and fishes; and the Anaima, or bloodless animals, included all the lower species.

Nothing, perhaps, can show more forcibly the nature and amount of observation required to frame a good classification, and the value of the information concentrated in its exposition, than the great and long-continued deference paid to this early step in the classificatory branch of zoology, and the minute and extended researches needed for the elimination of its erroneous element. First, it was found that many of the Exsanguineous animals of Aristotle did actually possess blood, differing only in colour from that of the so-called Sanguineous species. This discovery, however, led only to a nominal improvement in the primary division of animals; the Enaima being *red-blooded* and the Anaima *white-blooded* animals. It was reserved for Cuvier, in the course of his minute dissections of the lower animals, to discover that an extensive class of worms had red blood circulating in a closed system of arteries and veins; and this discovery first materially affected the value of the character adopted by Aristotle for the primary groups of the animal kingdom.

Now, if scientific classification were really based on the idea of likeness alone, and the grouping together of individuals into kinds in forming a natural system were regulated by a consideration of their resemblances only, then the modification of the Aristotelian system involved in Cuvier's discovery would be merely an extension of the group Enaima at the expense of the group Anaima; and the Anellides, or red-blooded worms, must have been united with birds, fishes, and other Sanguineous animals. But the zoologist, in the formation of a natural system, has to be governed at every step by the idea of difference as well as by that of likeness. Coincident with the discovery above mentioned, was the perception that if the Anellides resembled beasts in the colour of their blood, they differed from them in most other essential points; and thus the circulating fluid was rejected as a ground for the primary groups of the animal kingdom, and other characters were eagerly sought for.

Lamarck conceived that he had discovered the best substitute for the Aristotelian primary character in the vertebral column; this structure being present in all the Enaima of Aristotle, and absent in all the Anaima. He proposed, therefore, the name of *Vertebrata* for the one class, and *Invertebrata* for the other. The defect of this primary division of the animal kingdom was soon perceived to arise from the neglect of a third fundamental idea in a classificatory science, viz. that of proportion, or relative value, in the primary groups; and in the attempt to remedy this defect, the important discovery was made, that the vertebral column was a modification of structure subordinately related to a particular condition of an organic system of much higher importance in the animal body than the skeleton, viz. the nervous system. A knowledge of the anatomy of this system hence became essential to the zoologist; and the result of a long series of minute and elaborate dissections was the detection of at least three modifications of the nervous system of equal importance with that in regard to which a skull and vertebral column are dependent and subordinate. Hence arose the proposition by Cuvier to divide the animal kingdom primarily into four provinces or subkingdoms; viz. *Vertebrata*, *Mollusca*, *Articulata*, and *Radiata*; or, as they have been termed, in accordance with the modifications of the nervous system respectively characterising them, *Myelencephala*, *Heterogangliata*, *Homogangliata*, and *Acrita*.

All previous primary divisions of the animal kingdom (if we except some of the schemes of classification of the animal kingdom by John Hunter, found among his manuscripts after his death—see Preface to Palmer's edition of his *Animal Economy*) had been proposed in ignorance of the true characters by which such groups exist in nature. They are, therefore, now abandoned by the common consent of naturalists, nor would anything be gained by quoting them in this place. Herein the Linnæan method is inferior to the Aristotelian system: the class *Vermes* of the *Systema Naturæ*, as it included the *Ostracoderma* and *Malakia* of Aristotle, afterwards the *Mollusca* of Cuvier, with the true *Vermes*, was a retrograde step in this branch of zoological science.

The subkingdom *Vertebrata*, or *Myelencephala*, is subdivided into classes, according to the modifications of the respiratory and circulating organs. These modifications are essentially four in number, which may be thus expressed:—

1. Lungs suspended freely in a thoracic cavity; subdivided into minute air-cells. Heart divided into four cavities; pulmonic and systemic circulations distinct.

2. Lungs adherent to the walls of a thoracic cavity, communicating with large air-cells in other cavities of the body. Heart with four cavities; pulmonic and systemic circulations distinct.

3. Lungs suspended freely in or attached to the parietes of a thoracic-abdominal cavity; not divided into minute air-cells. Heart with

four or three cavities; pulmonic and systemic blood mixed in the general circulation.

4. Gills for respiration, with or without lungs. Heart with two cavities, transmitting all the blood to the breathing organs.

The first condition of the respiratory and circulating organs coexists with a viviparous generation, and lacteal organs for the nourishment of the new-born young; whence the class was termed ZOOTOCA by Aristotle, and *Mammalia* by Linnæus; and the latter term is retained, because it expresses a character which is truly peculiar to the class. The total or partial clothing of hair, and the other organic coexistences which proclaim the naturalness of the group in question, are mentioned under the term MAMMALIA.

The second condition of the respiratory and circulating organs characterises the class of Birds. It is associated in this class with an oviparous generation, a covering of feathers, and those other modifications of the vertebrate type of structure which are detailed under the head of AVES. This is the most natural and circumscribed of all the groups of animals of corresponding value. Both mammals and birds differ from all other classes of animals in being warm-blooded: whence they have been combined to form a group called *Hæmatotherms*.

The condition of the circulating and breathing organs which characterises the third class of vertebrate animals, called Reptiles, is associated with cold blood, and a covering of scales, bony plates, or a naked skin. Their generation is oviparous or ovoviviparous: the other characters are given under the head REPTILIA.

Fishes, besides breathing by gills, and having a heart composed of a single auricle and ventricle, have the skin defended by scales, or by bony plates, or are naked. They are likewise oviparous or ovoviviparous; and, with a few exceptions, as the tunny, the temperature of their blood corresponds with that of the surrounding medium. They are exclusively aquatic; and their general characters and classification are given under the heads ICHTHYOLOGY and PISCES. The two classes of fishes and reptilia are grouped together under the larger division of HÆMATOCRYA.

The subkingdom *Mollusca*, or *Heterogangliata*, is characterised by a ring of nervous matter surrounding the gullet, whence the nerves radiate, often unsymmetrically, to different parts of the body. There is a ganglion or little brain below the gullet, and sometimes also above that tube: the nerves of the body are generally connected with one or more detached ganglions. The form of the body corresponds with the disposition of the nervous system, and is often unsymmetrical; it is generally soft, covered with a mucous skin, and destitute of jointed limbs. In one class (*Cephalopoda*), in which the supraœsophageal nervous mass is large, it is protected by a cartilaginous cranium; but this is absent in other Mollusca, and a vertebral column exists in none. Many species have for their skeleton a calcareous plate or plates, called *shells*, developed by the skin. [CONCHOLOGY.] The animal functions are feebly enjoyed in the *Heterogangliate* subkingdom. Distinct organs of hearing and smell have as yet been found only in the highest class (*Cephalopoda*); the eyes are reduced to mere rudiments in the group next in subordination (*Gastropoda*); and the head is altogether wanting in the three lower classes, thence collectively called *Acephala*. The machinery of the organic functions, on the other hand, is largely and completely developed. Every mollusc has a heart, and a closed system of arteries and veins: in the higher Cephalopods the circulating system is physiologically as perfect as in the highest Vertebrates, and the heart is anatomically more complicated. An organ of respiration is never wanting; but it presents this character, that whereas in the *Vertebrata* it communicates with the mouth, in the *Mollusca* it is connected with the opposite termination of the alimentary canal. The *Mollusca* are either Diœcious or Hermaphrodite.

The primary division of *Mollusca* is, according to the presence or absence of a head, into the *Encephala* and *Acephala*.

The Encephalous Molluscs are divided, according to their locomotive organs, into the classes CEPHALOPODA, GASTROPODA, and PTEROPODA; the Acephalous Molluscs, according to their respiratory organs, into LAMELLIBRANCHIATA, PALLIOBRANCHIATA, and HETEROBRANCHIATA: the two latter classes are more commonly called BRACHIOPODA and TUNICATA. [MALACOLOGY.]

The third primary division of the animal kingdom, viz. the *Articulata*, is as well characterised, Cuvier states, as that of the *Vertebrata*. 'The skeleton is not internal, as in the latter; neither is it annihilated, as in the *Mollusca*. The articulated rings which encircle the body, and frequently the limbs, supply the place of it; and as they are usually hard, they furnish to the powers of motion all requisite points of support; so that we have here as many kinds of locomotion as among the *Vertebrata*. This external position of the hard parts, with the internal position of the muscles, reduces each articulation to the form of a sheath, and allows it but two kinds of motion, unless the limbs be united by flexible membranes, or fit into one another; and then their motions are more various, but have not the same force.

'The systems of organs in which the *Articulata* resemble each other the most is that of the nerves. Their brain, which is placed above the œsophagus and furnishes nerves to the parts adhering to the head, is very small. Two cords, which embrace the œsophagus, are extended along the abdomen, and united at certain distances by double knots or ganglia, whence arise the nerves of the body and limbs.

'Each of these ganglia seems to fulfil the

functions of a brain to the surrounding parts, and to preserve their sensibility for a certain length of time when the animal has been divided. If to this we add that the jaws of these animals, when they have any, are always lateral, and move from without inwardly, and not from above downwards, and that no distinct organ of smell has hitherto been discovered in them, we shall have expressed all that can be said of them in general.' The existence, however, of the organs of hearing, the presence, number, and form of those of sight, the kind of respiration, the condition of the organs of circulation, and the colour of the blood, present great differences, which characterise the subdivisions or classes of the Articulate or Homogangliate subkingdom.

These classes are: ARACHNIDA, INSECTA, CRUSTACEA, CIRRIPEDIA, and ANELLATA.

The first three are combined by Latreille into a large group, called *Condylopoda*, in reference to their possessing articulated members; but these are likewise possessed by the *Cirripedia*, which, although placed by Cuvier in the Molluscous subkingdom, are proved by their nervous system and metamorphoses to be essentially *Articulata*, nearly allied to the Crustaceans. With the Annelides the *Entozoa* are allied by close transitions: the *Bryozoa* have like relations to the *Tunicata*.

The Radiated, or fourth primary division of animals in the system of Cuvier, is so called because the low-organised species composing it agree, Cuvier says, in having their parts arranged round an axis, and on one or several radii, or on one or several lines extending from one pole to the other. The nervous system, when traces of it have been visible, is also arranged in radii. For classes of still lower organisms, sometimes ranked with animals, sometimes with plants, but not raised to the characters of either, see ANIMAL. The following table of the primary groups and classes of the animal kingdom is the most convenient:—

Kingdom ANIMALIA.

Subkingdom *Vertebrata*.

Hæmatotherma { *Mammalia*, *Aves* }

Hæmatocrya { *Reptilia*, *Pisces* }

Subkingdom MOLLUSCA.

Cephalopoda	*Brachiopoda*
Gastropoda	*Conchifera*
Pteropoda	*Tunicata*

Subkingdom ARTICULATA.

Insecta	*Cirripedia*
Arachnida	*Annelida*
Crustacea	*Entozoa*

Subkingdom RADIATA.

Echinodermata	*Anthozoa*
Acalephæ	*Hydrozoa*.

Zoonomy (Gr. ζῶον; νόμος). The branch of science treating of the laws of animal life.

Zoophytes (Gr. ζωόφυτον, *an animal plant*). The name given by Cuvier to his fourth and last primary division or subkingdom of animals. By Linné it was applied in a more restricted sense to an order of *Vermes*, comprehending those beings which were supposed by him to share the natures of both animal and plant. Mr. Hatchett's dissertation upon these subjects, in the *Philosophical Transactions* for 1800, contains nearly all the chemical information which we have respecting them. From their composition they may be arranged into four classes: 1. Those which consist almost entirely of carbonate of lime and gelatine. They are perfectly soluble (with effervescence) in muriatic acid, and the solution yields slight traces only of animal matter: when heated red hot, they evolve but little smoke or odour, and leave quicklime. Common white coral (*Madrepora virginea*) is an instance of this variety. 2. Those which, like the former, have carbonate as their hardening principle, but which when steeped in muriatic acid are less rapidly acted on, and leave membranous or cartilaginous films, and which, when heated, exhale smoke and the odour of burnt bone; these, therefore, consist of carbonate of lime, gelatine, and albumen. Such are the *Madrepora ramea* and the *Madrepora fascicularis*. The *Isis hippuris* is a curious variety of this class, in which separate portions of var. 1 are united by cartilaginous joints. 3. This class includes the *Gorgonia nobilis*, or red coral, the *Tubipora musica*, and some other varieties; the earthy part of which is not merely carbonate of lime, but contains a portion of phosphate of lime, whilst the animal part resembles class 2. 4. This class includes the various sponges. Some of these consist almost exclusively of what may be called *animal matter*, i. e. of a peculiarly organised albumen, with a trace of gelatine; others are hardened by abundant silicious or calcareous spiculæ. Mr. Hatchett has pointed out the resemblance which exists among the first three classes to porcellaneous shell, mother-of-pearl shell, and the crustaceous coverings of the crab and lobster.

Zoospores (Gr. ζωός, *living*, and σπορά, *seed*). A name given to the active spores of *Algæ*, belonging both to the green and dark-spored series. Their activity depends either on a general coat of short cilia on a circle at one extremity, or on two or more lash-like cilia variously disposed. The occurrence of spores endowed with apparently voluntary motion was formerly considered so surprising, that it was either rejected as unworthy of credit, or the organisms which produced them were considered as animals. It is now, however, generally allowed that there is no essential difference between animal and vegetable life, and that therefore the usual indications of either are not to be regarded as decisive of the especial kingdom to which beings belong in which they are manifested. Zoospores so long as they are free have indeed a great likeness to *Infusoria*, but as soon as they have found a fit resting-

place all traces of motion cease, and their offspring comports itself as a vegetable.

Zootoca (Gr. ζωοτόκος, *viviparous*). In Zoology, the name given by Aristotle to the class termed Mammalia by Linnæus. The name has, however, been restricted by some modern naturalists to a sub-genus of lizards distinguished by their viviparous generation.

Zootomy (Gr. ζῶον, and τέμνω, *I cut*). The branch of anatomical science which relates to the structure of animals generally. [Anatomy, Comparative.]

Zorgite. A name given to the varieties of Clausthalite in which part of the lead is replaced by cobalt and copper. [Raphanosmite; Tilkerodite.]

Zoroaster, more properly **Zarathustra.** The great legislator and prophet of the Bactrians, called by Plato a son of Oromazes [Ormuzd]. Of his personal history nothing is known. By some, Zoroaster is said to be a contemporary of Darius Hystaspis; by others, he is placed many hundred or even many thousand years earlier. (Gibbon, *Roman Empire*, ch. vii. with Milman's notes.) The Iranian lawgiver must therefore be placed in the class which includes Lycurgus, Numa, Romulus, Servius Tullius, Pythagoras, Zaleucus and Zalmoxis. The religion of Zoroaster, Dualism [Ahriman], was restored as the national faith of Persia by the Sassanidæ, 'the only instance, perhaps, of the vigorous revival of a pagan religion.' (Milman, *Hist. of Christianity*, book iii. ch. i.)

The Zoroastrian system is embodied in the Zend Avesta.

Zosteraceæ (Zostera, one of the genera). A small order of Endogens sometimes regarded as first of the group Fluviales. It consists of marine plants resembling seaweeds and living among them, but bearing long grass-like sheathing leaves, and perfect flowers enclosed in the sheathing bases of the leaves. They are found abundantly in the seas which border Europe, Asia, and North Africa, and also in the West Indies and Australia.

The genus *Zostera*, comprising two species, consists of marine herbs, usually growing in shallow water near the edges of the sea, their long rooting stems creeping along in the sand or mud, and sending up slender erect branches, bearing long narrow grass-like alternate leaves, sometimes forming such dense masses as to impede the passage of boats. *Z. marina*, the common Sea-wrack, Grass-wrack, or Grass-weed, has leaves varying from one to several feet in length, and rarely more than a quarter of an inch broad. These are commonly used for packing, and by upholsterers for stuffing mattresses and cushions, being sold for that purpose under the name of *Ulva* or *Alva marina*. They contain a small amount of iodine, and a considerable quantity of potash.

Zouaves. A class of soldiers in the French military service, whose name is said to be derived from that of a native tribe in Algeria. Originally the light infantry thus called were levied among the natives of that country; and their first organisation is attributed to General Clausel (October 1830, immediately after the conquest). Afterwards the corps was gradually, and is now exclusively, recruited in France, and consists chiefly of men transferred from the line to it as a corps d'élite. The natives are now enrolled in other corps, the 'Kabyle' infantry, &c., popularly known as Turcos. The French Zouaves first rose into European reputation in the Crimean war.

Zuinglians. In Ecclesiastical History, the followers of Zuinglius, the most advanced of the reformers of the age of Luther. Zuinglius regarded the sacraments as mere signs and symbols, and maintained that original sin was nothing more than a malady or evil tendency, in no degree involving guilt. He thus abandoned the notion of transmitted guilt, and the idea that children dying unbaptised can suffer for the lack of that which it was not in their own power or choice to obtain. With this doctrine he also abandoned of necessity the tenet of exclusive salvation, which was vehemently maintained by Luther and Calvin, and in all other reformed confessions. In the confession of faith written shortly before his death, Zuinglius describes that assembly of all the saints, the heroic, the faithful, and the virtuous, in which every upright and holy man who has ever lived will be present with his God. On reading this confession, Luther said that he despaired of the salvation of Zuinglius, while his practical advice was to hunt down the Zuinglians as mad dogs. It was only a natural consequence, that while Luther propounded and acted on this sweeping theory, Zuinglius opposed himself to the idea of persecution, and died fighting in the battle-field in defence of his liberal principles. (Hallam, *Literary History*, vol. i.; Lecky, *History of Rationalism*.)

Zumology (Gr. ζύμη, *leaven*, and λόγος). The doctrine of fermentation.

Zumometer or **Zumosimeter** (Gr. ζύμη, and μέτρον, *a measure*). An instrument intended to show the degree to which fermentation has proceeded in different fermenting liquors. [Saccharometer.]

Zurlite. A variety of Mellilite of an asparagus-green colour inclining to grey, which occurs at Vesuvius, generally in large rectangular prisms. Named after Signor Zurlo.

Zwieselite or **Zwiselite.** A variety of Iron-Apatite or phosphate and fluoride of iron and manganese, found at Zwiesel in Bavaria.

Zygadite (Gr. ζυγόν, from its occurrence in twin-crystals). A silicate of alumina and lithia found in thin tabular prisms and in twins like Albite, and of a reddish or yellowish-white colour near Zellerfeld in the Harz.

Zygæna (Gr. Ζύγαινα, the name of a fish in Aristotle). A genus of Cartilaginous fishes of the Squaloid or Shark tribe, remarkably characterised by the extreme breadth and flatness of the head, the sides of which extend outwards at right angles with and far beyond the body, just as the head of a hammer is placed on the handle: the eyes are placed at

the lateral margins of the head. The term *Zygæna* has also been applied by Tchsenheimer to a genus of *Lepidoptera*.

Zygænocephalus (Gr. ζύγαινα; κεφαλή, *the head*). A species of frugivorous bat allied to Pteropus, which has been described by Mr. A. Murray, from the Cabra river, Western Africa. The head is swollen and the nostrils inflated, so as to give to this remarkable cheiropterous form the appearance of having the head of a hippopotamus.

Zygantrum (a word coined from Gr. ζύγον, and ἄντρον, *a hole*). The articular cavity at the back part of the neural arch of the vertebræ of serpents and some lizards, which receives the zygosphene.

Zygapophysis (Gr. ζύγον; ἀπόφυσις, *a process*). The articular or oblique process of the vertebra, by which it is connected with the adjoining vertebræ.

Zygodactyles (Gr. ζύγον, and δάκτυλος, *a finger*). The name given by M. Temminck to an order of climbing birds, including those which have the toes arranged in pairs, two before and two behind; corresponding to the *Scansores* of Cuvier.

Zygoma (Gr. ζύγωμα, from ζύγον, because it transmits the tendon of the temporal muscle like a yoke). The cavity under the *zygomatic* process of the temporal bone. Hence, also, the term *zygomatic muscles*.

Zygophyllaceæ (Zygophyllum, one of the genera). A natural order of hypogynous Exogens, nearly allied to *Oxalidaceæ*, from which they differ in many characters; to *Simarubaceæ*, with which they accord in the stamens springing from the back of an hypogynous scale; and to *Rutaceæ*, from which they are distinguished by the leaves being constantly opposite, with lateral or intermediate stipules, generally compound, and always destitute of pellucid dots. They are shrubs or herbs, widely dispersed over the tropical and warmer parts of the globe, but occurring sparingly in temperate climates. They are characterised by their opposite stipulate leaves, their few-seeded finally apocarpous fruits, the pericarp of which does not laminate, and their albuminous seeds. The ligneous plants of this order are remarkable for their hardness. *Guaiacum*, or *Lignum Vitæ*, is one of them.

Zygosphene (Gr. ζύγον, and σφήν, *a wedge*). The wedge-shaped process from the fore part of the neural arch of the vertebræ of serpents and some lizards, superadded to the ordinary anterior zygapophyses, and articulated to a cavity in the antecedent vertebra.

Zymotic (Gr. ζυμωτικός, from ζύμη, *leaven*). In Medicine, diseases caused apparently by the reception into the system of a virus or poison, which is diffused through the frame, and operates upon it like a ferment or leaven. In the Registrar-General's Report, the following diseases are grouped together as *zymotic*: smallpox, measles, scarlatina, hooping cough, croup, thrush, diarrhœa, dysentery, cholera, influenza, purpura and scurvy, ague, remittent fever, infantile fever, typhus, metria or puerperal fever, rheumatic fever, erysipelas, syphilis, noma or canker, hydrophobia.

THE END.
